**Forming Special Joints in Stone.** Besides employing other materials to strengthen the joints between successive courses of stones, there are various methods used for strengthening such joints in the process of dressing the stone itself. Nearly all these methods involve a considerable amount of labour and some waste of material, and they are reserved for positions in which such additional strength as they give is essential.

The most usual of these is *jogging*, which has already been described [see page 2783]. If a stone head be built up of a series of small stones resembling terra cotta blocks, the same system of jointing them may be employed, but, as a rule, it is possible in masonry to get stones long enough to span any openings of ordinary length which it is essential should have a lintol and not an arch over them. But jogging is very usually employed for landings [150], where comparatively thin stones of considerable area have to be jointed up, and in such cases the joggle is usually stopped some little way back from the face of the stone, and is formed as a slightly tapering projection fitting into a corresponding mortice or sinking in the next stone. A rebated joint is sometimes used for landings, and sometimes a sinking is formed in the heading of each stone, and a long slate dowel inserted. This is more easily cut, but is less efficient than a joggle.

**Tabled Joints.** For strengthening horizontal joints *tabling* is sometimes resorted to [154]. This consists in working a projection on the upper bed of one course of considerable area and providing a corresponding sinking in the succeeding course into which it fits. This forms a strong joint, but entails a good deal of labour and waste, and is required only where there is likely to be considerable lateral strain, either as the result of shock or thrust. Such a joint is used in marine

161. SUNK JOINTS TO VOUSSOIRS, WATERLOO BRIDGE, LONDON

joint; this is first let into the heading of one stone and run with cement, and afterwards the next stone, which has had a cavity prepared for it, is placed against it [146].

**Vertical Cramps.** Occasionally it is necessary to unite two successive horizontal courses with a metal tie. One end may be enlarged, roughened, and let into the lower stone, and the upper end passes through a perforation in the course above and is tapped and fixed by means of a washer and nut. Another method of fixing the lower end without the use of either cement or lead is to form the lower part of the hole formed for the bolt in the form of a cone spreading towards the base. The rod has the lower end split by three or more cross cuts, and is fixed by inserting in the bottom of the hole a prepared metal cone, resting usually on the upper surface of the course below. The split

work, and in the lower course of spires, where horizontal joints are used; but for the latter a simple rebated joint may also be made use of. For very special work, as in the foundations of the Eddystone Lighthouse, the stones were very carefully framed together with dovetailed joggles [151] so as to withstand the shock of immense waves bursting against the base.

**Jointing Copings and Weathered Surfaces.** In jointing the copings of sloping gables a rebated joint should be used to prevent the penetration of wet to the wall, and care must be taken to see that the point *a* is lower than the point *b* [152], so that, in the event of the mortar perishing and water getting into the joint, it will pass out again and not get through the joint to the wall.

This form of joint is used when the upper surface is in one plane; but copings and water tables are often finished by using slabs not of uniform thickness, but tapered so that the lower edge, which is thick, is rebated over the thinner upper edge of the next block, and it may be provided with a small hollow moulding to serve as a drip.

For stones of which a large part of the upper surface is exposed to the action of the weather, as in the case of the large projecting stones of a cornice, there would be some danger that water would find its way into the joints of the upper surface which is *weathered*—that is, worked to a slope to throw any water falling upon it towards the edge. To protect such joints the weathering is not carried through the entire length of each stone, but at each end of it a narrow band or fillet of stone is left raised [153]. This may represent the original surface of the block, or it may itself be slightly weathered. The outer edge of the fillet corresponds with the heading joint; the inner edge is rounded off to meet the weathered surface, and this form of joint is termed a *saddle-back joint*.

#### **Moulded and Enriched Work.**

We have dealt so far with perfectly plain work built to form various classes of walling; and we may note that every stone must be to a greater or less extent wrought or dressed before it is built in, whereas most bricks are employed just as delivered. With masonry, therefore, to a greater extent than with brickwork, there are facilities for varying the surfaces, and particularly the arrises of the blocks, by the employment of mouldings, which give an added interest and beauty to the lines surrounding an opening, or in the form of bands or courses of mouldings; the highest art of the mason is exhibited in the setting out and working of moulded and enriched work on wall surfaces, including arcades and niches, in openings with tracery enrichments, and in vaults and domes. Such work often requires an advanced knowledge of geometry to enable the mason to set out his work as well as high technical skill to execute it.

But however great the elaboration of the enrichment or the irregularity in the form of the block to be worked the mason must start from a simple block of stone and reduce it to a regular shape, on which he can set out his mouldings, and from which he can sink his irregular surfaces, and all stones, whether elaborate or simple, go through the same kind of processes.

**Method of Sinking Mouldings.** The method of squaring up a stone has been already described. Let us assume that we have such an oblong block of stone which is to form part of the cornice of a building, and consider the processes of reducing it to its ultimate form. The mason is supplied by the architect with a full size section of the moulding to be worked; this is first transferred from the drawing to a

162. RUSTICATED MASONRY, SOMERSET HOUSE, LONDON

sheet of zinc on which the outline or profile is marked with a sharp point and then cut out accurately, so as to produce a very thin section of the exact form of the block to be worked. This section is termed a *template*. If, now, our block has been accurately reduced to the thickness of the finished stone, the template may be applied first to one end of the stone, and its outline scribed on the stone with a sharp point; it is then applied to the other end, and again scribed [155]. There will generally be found to be certain well marked planes which approximately contain the lines of mouldings within them, and these are also marked in the ends of the stone. The two ends of every such plane are marked on the face or bed of

the stone, and are connected by a line scribed on the surface. The first process is to knock off the superfluous stone and reduce the block to a shape approximating to the finished form, and for this work the pitching tool is often used. From this face the mouldings, if they be close to it, may be sunk direct, or, if necessary, further general sinkings may be made, and in marking and forming these the bevel comes into service; for the main surfaces being no longer at right angle, the square cannot be used. In every case where the moulding runs throughout the length of the stone, each successive plane is worked off along the whole length before the final process begins. In working the mouldings they are first roughly chiselled to their approximate size and shape but about  $\frac{1}{4}$ th in. full, and they are finally cleaned up with narrow and rounded chisels; but the ends of such mouldings for an inch or two next the heading joint are often not cleaned up till after the stones are fixed, to facilitate any slight adjustment of the alignment that may be required. The straightedge is used to test the accuracy of the long lines frequently, and care must be taken in the early stages not to sink any part of the work below the level of the finished face.

**Mouldings in Circular Work.** In the case of mouldings worked on a curved surface, as, for example, in the case of a moulded vaulting rib or an arch stone, the process is similar, but the block, after being squared, is next reduced to the form of the required curve before the sinking of the mouldings is taken in hand [156], and in doing this a face-mould is employed to mark out the curved block.

**Winding Surfaces.** For some purposes it is necessary to give to the stone not a true but a winding face; to do this, in place of using two parallel-sided straight-edges only one such is used, while the other has diverging edges set out to give the amount of twist required. The distance apart of the rods must be accurately fixed. The parallel-sided straightedge is placed on the near edge of the block of stone on a draft prepared for it, the other being applied to the further edge, on which a draft is worked down till the upper surfaces are found to be level when boned. Straight drafts are then worked along the sides of the stone connecting the two ends of those first formed for this purpose, the two ends are subdivided into any convenient number of equal parts— $a^1$   $a^2$   $a^3$  and  $b^1$   $b^2$   $b^3$ , etc.; then straight drafts are worked

across from  $a^1$  to  $b^1$ ,  $a^2$  to  $b^2$ , etc., and the intervals between them may be again subdivided and worked off similarly [157]. Such a surface is required in the soffits of stairs and for skew arches.

**Working Cylindrical Blocks.** In working a plain cylinder, the block must first be squared, the circle scribed on each end; and a series of points on the circumference found. The two diagonals may be drawn, and where they cut the inscribed circle four points are secured, and any number of intermediate points may be found. The cylinder may first be reduced to an octagon by setting out an octagon enclosing the circle and working off the angles, and straight drafts are then chiselled down the side from end to end of the stone [158]. If the column is diminished—i.e., if one end is to be smaller than the other—it will be necessary only to inscribe the two circles of the correct sizes; the diagonals, by their intersection, fix the centre or axis of the column at each end, and will divide each circle into four exact quadrants, and care must be taken to subdivide each of these into the same number of parts; in other respects the work is carried out as for a simple cylinder.

If the block is not only to be diminished but to have an *entasis*—that is, a slightly curved outline—it will be necessary, instead of using a straight edge for testing the working of these drafts, to have a profile cut to the exact curve required, which may be applied in the same way as a straight edge. In the case of all circular work, whether plain, as above described, or moulded, as in the case of balusters, the stones where machinery is available may be turned in a lathe.

**Cutting Voussoirs.** In cutting the blocks or voussoirs to form an arch it is not necessary to reduce every stone to a square block as the first process; but a long stone having first been squared, the shape of the blocks may be set out on the face and back by using the face-mould and reversing it for every alternate stone, and cutting out the blocks with a saw; sufficient room for the saw-cut must be left, and the sides of the voussoirs can be afterwards dressed with but little labour [159]. This method economises both stone and labour. So, also, two spandrel-shaped steps may be sawn out of a rectangular block of stone, provided they are of uniform section throughout and are not required to have a square seating for building into a stone wall.

page 1871

## GROCERS

We shall consider the business of a grocer who is also an Italian warehouseman. The Italian warehouseman, who at one time dealt in foreign fruits, lemons, oranges, olive oil, macaroni, and sardines, has become almost extinct as a separate tradesman, although here and there a department of this kind is carried on in conjunction with the trade of a general fruiterer. Practically, the trade is now merged in that of the grocer, who is also frequently a provision merchant, an oilman [see OIL AND COLOURMEN], and a wine and spirit merchant or bottled beer retailer under an off-licence; in fact, many modern grocers adopt the "sell-everything" principle which has proved so successful in the great stores. The theory is that customers who visit a shop to buy one article often buy others, and that it is wise, therefore, to leave them no excuse for seeking a rival trader's establishment.

**How to Start.** Many of the most successful grocery businesses have grown from very small beginnings. The grocery trade is one in which the personality and energy of the proprietor count for much, especially where the business is in its infancy. Also it goes without saying that the grocer beginning business should have a practical knowledge of his trade, although many a business has been started from the germ of a small general shop by persons whose only technical knowledge lay in acquaintance with a larger shop from which to buy "to sell again." Where such ventures succeed, it is usually because they possess the essential justification of existence in meeting the wants of a neighbourhood not better supplied. Villages, new suburbs, districts of all kinds, as a rule, grow, and shops grow with them. Many grocery shops have been started by young managers who have obtained a knowledge of a locality, and perhaps espied a growing corner when in the employ of old-established firms. But nowadays grocers when engaging assistants generally protect themselves against this by "restraint" agreements, under which the assistant binds himself not to start in business within so many miles of a given town until the expiration of a term of years after leaving the employer's service, under penalty of a named sum as liquidated damages.

**Capital.** Thus the question of starting becomes largely one of the capital at command. If the would-be grocer has money enough, he may often find advertisements in the trade papers of businesses to be bought as going concerns—in which case, goodwill, "the benefit arising from connection and reputation," may have to be purchased besides the fittings, stock, and book accounts. The services of a trade valuer should

be requisitioned in buying a business, and the buyer should be on his guard against being saddled with old stock, while he should also take care that debts and running accounts are made over to him in proper legal form lest he should subsequently need to prove his title thereto. But if the beginner has no more capital than the £170 or £200 mentioned elsewhere as the indispensable minimum, he is hardly likely to purchase a business. What he will probably do, either alone or in conjunction with a reliable friend of similar views, is to spy out the land until the suitable "pitch" for a new shop is found, then seek out the suitable shop, having regard most carefully to the length of his purse. He has to provide for (1) fitting the shop; (2) stock and renewal of same as required; (3) rent, rates, wages (if any), and working expenses; (4) his own maintenance.

**Selection of Premises.** In selecting premises for a shop, the first consideration will be, as a rule, the position, in view of the class of trade expected to be done. As the beginner's purse is so limited, he can hardly expect to obtain one of the coveted corner sites that are so valuable in all growing neighbourhoods for trades where the window display counts; but he will at any rate look out for a shop that has a good window, or possibly two windows; that does not get too much sun, though not in the shade; that has not a front door likely to get all the dust of the street; that has a room at back, or over, suitable for a stock-room, also a dry cellar if it be the intention to keep provisions. Take care, further, that the drainage is satisfactory, and that there are no rats. The rent of a shop for a grocer beginning business on £200 or so of capital can hardly exceed £50, with safety, and probably £30 or £35 will be the better limit, though this depends largely on circumstances.

**Fittings and Fixtures.** A good facia is always necessary for a grocer, and "good" does not mean one of the cheap and gaudy kind. Each window should be of plate glass in one piece where possible. "Fixtures" in a shop are ordinarily those fastened to the ceiling, walls, doors, and floors, while "utensils in trade" are movables; and it may be noted that fixtures and fittings which a tenant puts up in a shop for the purposes of his trade remain his property, and can be taken away by him. Having decided what amount of his ready cash he can allot for fixtures, fittings, and utensils in trade, the shopkeeper will doubtless call in the services of one of the regular shop-fitters to the trade. Unless second-hand counters and "fittings" can be obtained, and boxes utilised for ekeing out shelves and drawers, it will hardly be possible to expend less than £50 or £60 on fixtures and fittings, and very much

## SHOPKEEPING

more might easily be spent. Mahogany or baywood is needed for the top of the grocery, and white deal for that of the provision counter. Glass signs, bacon-rails, sunblinds, butter-stands, tea-canisters, a small coffee-mill, a currant cleaner, scales and weights, a truck, step ladder, vinegar measures, syrup-can—in such ways the money goes. Gas-fittings should be very carefully placed to give the best possible light.

**A Model Grocer's Shop.** The view given of an interior [1] fitted by Messrs. Maund, of 344, Old Street, London, E.C., suggests what can be done.

A brief description, with prices of fittings such as are shown, will assist the beginner to estimate the cost and will teach him how far his purse will stretch. The principal fixture is the wall fitting, which should not be less than 16 ft. long, 9 ft. 6 in. high to the top of the cornice, and 18 in. deep at the bottom part. The lower part to a height of about 2 ft. should be provided with continuous ranges of open lockers about 2 ft. long and in two heights.

Above these in the shop shown are patent tea-bins with metal-lined receivers under which is an ingenious fitting whereby the tea stored in the bins—to the amount of 60 to 80 lb.—flows automatically into the receivers beneath. The latter have lids for easy access when serving. This ensures that the bulk of the tea is kept from the air, and another important point is that the dust is sold together with the tea instead of accumulating in the last few pounds removed.

The fronts of the bins are decorated in gold and colours, a useful medium for advertisement, and, being at the eye level, are always prominent. An alternative design has mirror panel doors in front of the bins, which are decorated on the back of the glass. Between the bins are nests of spice drawers with glass fronts, having about  $\frac{1}{2}$  in. space at the back of the glass in which samples of the goods in the drawers are shown. Along the tops of all is a shelf for tea canisters, and above this a shelf for seed-tins. These, of course, can be used for packed or other goods at pleasure. All the fitting is faced on front with polished mahogany to ensure long wear.

In the centre of the upper part of the fitting is a plate glass and mahogany case for scents, patent medicines, or delicate goods requiring care to prevent depreciation by dust and air. The whole fitting is mounted with an artistically moulded cornice faced with polished mahogany and birdseye maple.

The ornamental pediment over the case is to match the cornice, and, if desired, an eight-day clock can be fitted in the centre. If the ceiling is not at least 15 in. above the top of the cornice, it is sometimes advisable to dispense with this pediment and to fit the cornice at the level of the ceiling.

The counter should be as long as the site permits, and should never be less than 24 in. wide or more than 2 ft. 11 in. high. The top of that in the model shop shown is of polished mahogany, 1 in. thick and thickened out on

front and ends with a light moulding. The front should be framed of solid mahogany and panelled with veneered birdseye maple, the mouldings being of belection or raised pattern.

The fronts may be upright or slightly sloping. The interior of the counter should have two rows of drawers for fruit and sugar, the top row about 15 in. long and the bottom row about 23 in. long, with skirting underneath, which should be recessed about 2 in. so that it is not in the way of the assistants' toes. On the top of the drawers should be rows of spaces for wrapping paper. A neat addition to this counter is a few display shelves of glass, 15 in. by 18 in., mounted on brass pillars about 30 in. high rising from the back of a small bent-fronted glass case about 18 in. long and 8 in. high with a door at the back. If these are placed on the counter about 3 ft. apart, the spaces between suit as serving places for assistants.

The wall fitting described is worth, per foot run. 65s. to 68s., or, with canisters, 70s. to 73s. The counter costs per foot run, without show cases described, 20s. to 22s.

The price of tea canisters to hold 14 lb. each is 7s., or included in the cost of the fitting, would make the latter 70s. to 73s. per foot run.

**Other Fittings and Appliances.** The grocer beginning with £200 cannot afford first-class fittings, but he will usually find it better to avail himself of trained and expert advice than to trust to his own ingenuity and the skill of the local carpenter. A common practice is to divide the shop into two departments—a grocery side and a provision side, each with its own window and separate counter and fittings; while in the centre of the shop may be placed show frames for green fruit, lemons, bananas, oranges, tinned goods, etc., and at the rear end a special fitting for such things as brushies, etc. A coffee roaster is a useful and necessary piece of machinery. Tea mills and mixers are not needed unless the grocer blend his own tea—a practice which has been dropped by many. Proper tea-bins are needed, however, as tea deteriorates unless the air be excluded from it. Warehouse bins, with rounded bottoms, are now commonly made of galvanised steel. When the grocer possesses suitable machinery for the purpose, it is often found an attraction to roast and grind coffee in the window.

In the same way a bacon-slicing machine, which is capable of cutting remarkably thin slices, is often a great "draw." Window-dressing is itself something of a fine art, and one that is well recognised as influencing trade and gaining customers. Ingenuity and an eye for colour and general effect are the personal qualities necessary; the other factors are a suitable window (as to which the shopfitters are the best guides) and suitable stock. Smart-looking tickets, and not too many, should be used. A good plan is to make special displays of seasonable goods—e.g., a window of house-cleaning materials and paraphernalia when the spring cleaning is at hand—and to change them frequently. Moving figures are often used, but though originality always counts, too much fondness for the stage properties and trappings

1. THE INTERIOR OF AN UP-TO-DATE GROCER'S SHOP

models affected by some dressers is not advisable for the grocer.

**Plan of Business and Stock.** This will depend naturally on the needs of the neighbourhood for which the grocer intends to cater, and the extent of his means for so doing. If there be a wholesale house in his neighbourhood it will be an advantage, since provisions and other goods lose weight rapidly by evaporation when kept in a shop, and this loss in shrinkage may be minimised by keeping stocks as short as possible. Moreover, the fresher goods are the better. It should be possible to buy provisions so that the capital invested in stock shall be turned over 52 times a year, and to buy groceries so that the capital shall be turned over eight times or more in a year. With regard to such staples as tea and coffee, it is necessary to take especial care to buy in the right quarter. Nowadays, comparatively few grocers in a small way buy "originals"—teas as originally packed at the tea gardens; nor do they carry out their own milling, mixing, and blending. They buy ready blended teas from a house on which they can rely; and there is the extra advantage in this, that the blend which customers are found to like can be more readily continued without noticeable change, although, of course, the ingredients are constantly varying as supplies of particular leaf give out or the character of a new crop changes. Avoid packet teas,

and study the water of your locality. Coffee should also be a strong point; like tea, it is one of the things by which customers judge their grocer, and which they criticise among themselves, either to his disadvantage or his good reputation. If possible, the grocer should always roast his own coffee, roasting, if a proper machine be used, being quite a simple process, though demanding skill and care, and when properly performed being a good advertisement, since it gives his coffee the absolute freshness which is so much appreciated. It is by no means necessary to buy an expensive and elaborate roaster; the best in practical use are also the simplest. In addition, a good mill should be employed for grinding the coffee. Of sugar, butter, bacon, and cheese a ten days' supply will usually suffice; of any other goods a month's sales, at most, will suffice. In first stocking, make out a careful list of stock required and get two or three good wholesale houses to quote for cash. On every invoice insist upon a guarantee of purity, such as "All goods named on this invoice are guaranteed genuine," and this must be either signed or initialled in handwriting, care being also taken that the goods are really named, not simply "black" for "black pepper," and so on.

**Terms and Discounts.** The retailer should always make a point of getting the utmost discount his means allow. Best possible

## BOOKKEEPING

terms are obtained, of course, by those who buy for cash and in large quantities. So that it is sometimes possible for men in a small way to get level with their bigger competitors by combining their orders for certain goods, and "combination buying," especially for certain well-known proprietary goods which everybody stocks, is coming more and more into vogue, often through the medium of the grocers' associations which now exist in so many towns and country districts. Certain goods also are bought subject to special terms and conditions. These particulars are too long to be quoted here; the shopkeeper can hardly carry on his business intelligently without informing himself of such matters by buying and studying the detailed year-books or diaries issued by the trade papers—for instance, "The Grocer" Diary, published annually.

**Stockkeeping.** Another detail, which is, nevertheless, of great importance, is the keeping of stock and its allocation in shop, cellar, warehouse, or all of these. The details will depend on the accommodation available—the shopfitters will usually be able to give good advice—and a variety of hints on the treatment of the multifarious goods a grocer handles will be found in "The Practical Grocer," a four-volume guide to the trade and allied branches, published by the Gresham Publishing Company. Briefly, the cellar is best for stores of provisions, wines, or goods that require a cool and even temperature. The warehouse with a back entrance should have bins for sugar, etc., shelves for sauces, jam, pickles, unused paper bags, twine, and so on. Note the condition of walls and the relative dryness and heat of different positions in warehouse or shop. If a wall be damp, the shelves upon it are unsuited for cornflour, cocoa, or jam, but may serve for canned goods and mineral waters. Hot shelves near the ceiling are not suited for candles and nightlights. It is particularly necessary that such scented articles as soap or onions should be kept away from goods that readily absorb odours, such as tea, butter, cornflour, baking-powder, and flour. Drawers are convenient for rice, sago, sugar, spices, etc., and should be filled up every morning from the warehouse. Have a place for everything, and keep everything in its place. Weigh, count, measure, or gauge, as required, everything that is bought; neglect of this elementary rule is a fruitful source of loss. Either the grocer himself or a competent deputy should receive and check all goods as they come in, noting and reporting all damaged or faulty goods, or inaccuracies of account or carriers' charges, and so on. A "buying book" should record all goods purchased, with price terms and other remarks, and the stock should be inspected every day that wants may be noted and older goods pushed forward before newer. For heavier goods, such as tea, sugar, rice, cheese, a stock book, or warehouse book, is useful to show weekly the amount of stock, quantity added or sold, and stock at end of week, with such remarks as "sale brisk," "price falling," "bought too dear."

A "wants" book or slate is often kept. In a fairly large shop the "grocery side" may be usefully divided into compartments—say (1) biscuits, jams, canned fruits, patent medicines; (2) cocoas, chocolates, teas, patent foods, extracts of meat, bottled fruits; (3) toilet soaps, perfumes, candles, boot and furniture creams, polishes, and so on.

**Account Books.** Where a business attains respectable dimensions the proper double-entry system of bookkeeping is always best. But it is certain that very many smaller businesses are successfully conducted without it. A set of books which some grocers find suits their needs consists of (1) journal, or day book; (2) petty sales ledger; (3) sales ledger; (4) purchase book; (5) bought, or merchants' ledger; (6) cash book; (7) detailed cash and credit book; (8) petty cash book; (9) private ledger. In very many businesses conducted on a cash basis, and in some where credit is given, it is found a great saving of time and labour to use "duplicate" or "triplicate" books, so that the first writing of the order provides the necessary record and check slip. There are also several useful "systems" for saving unnecessary repetition and labour in the proprietor's own particular accounts.

**Rates of Profit Necessary.** In a brisk cash business on a limited number of articles  $12\frac{1}{2}$  per cent. gross profit may prove sufficient, while in a credit business, where orders have to be solicited, goods delivered by horse and cart, and periodical accounts rendered, 20 per cent. may be too little. The "Practical Grocer" quotes as results obtained from certain actual experience: Wages,  $3\frac{1}{2}$  per cent.; rates, taxes, licences, and insurances, 1 per cent.; lighting, heating, and general repairs,  $\frac{1}{2}$  per cent.; paper, twine, pins, etc., 1 per cent.; incidental expenses and depreciation, 1 per cent.; delivery of goods, hiring, etc., 1 per cent.; total,  $8\frac{1}{2}$  per cent. But horse-and-cart work alone may account for as much as 4 or 5 per cent. in some businesses. Reckoning rent in addition to the above, and allowing for breakages, spoilt stock, bad debts, etc., interest on capital, and 6 per cent. as a reasonable net profit, it is calculated that from 15 to  $17\frac{1}{2}$  per cent. gross profit is needed, and this should be reckoned not on cost, but returns. The grocers' associations commonly advise that even proprietary articles, which are sold in packets and simply handed over the counter as supplied, should show a profit of 15 per cent. for safe trading. In a large grocer's business the percentages of gross profit will probably be as follows: Tea, 16 per cent., stock turned over eight times in a year; coffee and cocoa, 21 per cent., twice to three times; sugar,  $2\frac{1}{2}$  per cent., ten to twelve times; biscuits, 11 per cent., seven times; jam, 15 per cent., twice; dried and tinned fruit, 15 per cent., three times; green fruit, 14 per cent., weekly; soap and candles, 21 per cent., three to four; small grocery sundries, edible, 20 to 30 per cent., twice; household sundries, non-edible, 20 to 25 per cent., twice.

**Assistants.** The number of assistants varies greatly, of course, according to the nature and requirements of the business. A small grocery shop may be run by the proprietor himself with the aid of a single assistant and a boy. In a typical London shop there may be, say, five grocery and two provision assistants, a clerk or bookkeeper, cellarman, vanman, and porter. In a typical good class grocery and provision shop in the country there may be a "first hand," or "manager," two other assistants—one of whom is a "provision" hand—an apprentice, a porter, and a couple of errand boys. "Living in" is becoming less and less common. Where the men live out an hour for dinner and half an hour for tea is usually allowed. Managers give or receive a month's notice; other assistants commonly a week. In many shops rules are enforced, each assistant being obliged to hold a copy and to give his written assent to them. Fines are only deducted legally when the assistants have thus assented. A grocer's assistant is not a "workman" within the meaning of the Employers and Workmen Act, but comes under the Truck Act.

**Side Lines.** Provisions are most commonly sold in the same shop with groceries. They are discussed in a separate article in this course. Other side lines and allied trades or branches of the trade are, as indicated above, very multifarious. Oils, fermented liquors (with licence or licences), tobacco (with licence), china and earthenware, patent medicines (with licence), and green fruit may be mentioned. For hawking any groceries that are not victuals a hawkor's licence is needed.

**Cash and Credit.** Many grocery businesses are now conducted on strict cash lines; but mixed cash and credit is very common. In a "family" business, in which profits are commonly good, it is often next to impossible to insist upon cash, and a credit trade, conducted with caution and due inquiry, is found steady and lucrative. It is wise to be on one's guard against the prevalence of fine furniture supplied to needy debtors on the hire system.

**Laws and General Policy.** The Food and Drugs Acts, Margarine Act, and Merchandise Marks Acts, which are more fully dealt with in the article "Provision Trade" [q.v.], are mainly those which apply to the grocer's business. As regards his shop, he has to pay attention, as a matter of course, to the laws on shop hours, seats for assistants (females), children, sale of goods, weights and measures, and so on. A special point is that of weighing paper with goods, which so far seems to be allowable when the goods are such as are commonly sold wrapped in paper, provided that the paper is of reasonable weight and thickness; it is not permissible to sell a great quantity of tea-lead at the price of tea. Under the Food and Drugs Acts goods that are mixed, such as coffee and chicory, may be sold provided there is a declaration to the purchaser, which may be by means of a printed statement on the wrapper. But the added article must not be such

as increases the bulk fraudulently. In the case of coffee, it would cease to be even conventionally called "coffee" if more than 50 per cent. were chicory; it would then become chicory to which coffee was added, rather than vice versa, and should be labelled "chicory with coffee." But the whole of the Food and Drugs Acts should be carefully studied by every grocer. In his general policy his whole aim should be to give his customers intelligent, honest, civil, and efficient service; he should try to make his own personality so acceptable and useful to them as to outweigh the advantages he cannot command, since at large stores the lower working expenses and the ability to buy better are sometimes counterbalanced by the necessity of employing none but paid assistants, who have not the proprietor's keen personal interest in their work. A well-trained, well-informed, intelligent, and energetic grocer working his own shop at a reasonable rate of profit can usually do something more than hold his own, no matter what the competition.

**Trade Instruction.** An excellent course of technical instruction for those engaged in the grocery and provision trade is given at the Borough Polytechnic Institute, London, and should be taken advantage of by every ambitious grocer who can make it convenient. The course consists of over 20 lectures, beginning in the month of October, and the cost of attending the lectures is 7s. 6d. The scope of the instruction will be best indicated by giving a synopsis of the subjects:

#### GROCERIES

**TEA, COFFEE, AND COCOA.** Countries of origin and kinds, preparation, shipment, market and prices, blending and preparation for sale at home, relation to waters of different districts, judging of quality and value, practical tests for purity, etc. Special attention to the detection of adulterants.

**SUGARS, CEREALS** (rice, tapioca, sago, flour, and various meals), **DRIED FRUITS.**

#### PROVISIONS

**BACON, HAMS, AND CHEESE.** Various cuts, character of the supplies from different countries, processes of preparation for market and their comparative effect on the value of the product, method of handling so as to show a profitable result.

**BUTTER, MARGARINE, AND BUTTER SUBSTITUTES.** The chemistry and natural history of butter; judging its value, keeping qualities and specially its purity, freedom from excess of moisture, artificial colouring, and preservative and adulteration.

#### TRADE LAWS

**GENERAL.** Landlord and tenant, method of holding property, taxation and rating—the Income Tax, duties and licences, master and servant agreements, recovery of debt, bankruptcy, etc.

#### SHOP MANAGEMENT AND ROUTINE

**SPECIAL.** The Food and Drugs Act, the Margarine Acts, the Shop Hours Acts, etc.

Buying and stockkeeping, window dressing, staff management.

The lecturers are successful practical experts in the subjects which they teach, and no grocer can attend the classes without learning much regarding the science of his trade.

**The Licensed Grocer.** Many grocers are also wine and spirit merchants, or sell beer for consumption off the premises. So far as England is concerned this branch of the trade

## SHOPKEEPING

was greatly developed as the result of Mr. Gladstone's action in 1860, when he reduced the duty on the light French wines, and created a new licence to enable those wines to be distributed by the grocer rather than by the older branch of the licensed trade. The capital required for such a branch of the grocery business, or even for an off-licensed business as a sole trade, is not very large; and the facilities offered by the large wholesale firms enable it to be prosecuted without any difficulty. Some of these firms will not only supply the liquor in bottles ready for sending out, but also procure the licences necessary. It is this simpler branch of the licensed trade with which we are here chiefly concerned. To conduct a business in which wines or spirits are bought in the wood and bottled by the merchant himself requires not only capital but very considerable experience and training. It should be noted that in the licensed trade each part of the United Kingdom has its own special laws and licence regulations—and these laws are not only numerous but in many points involved and intricate.

**Licence Needed.** No person can carry on a business in intoxicating liquors without (a) a licence from the magistrates; (b) a licence from the Excise and Inland Revenue authorities. The magistrates' licence is granted at a special session held in February each year. Before appearing to apply for it the applicant has to give and to publish various notices. He has to give notice to the overseers of the parish where his shop is situated, and to the Superintendent of Police; and to exhibit a notice on the door of the premises, on the church door or some conspicuous place if there be no church, and also in a local newspaper. If the magistrates grant the licence it has to be confirmed at another meeting of the justices, and in granting or refusing it the justices have absolute discretion, while the applicant must not only prove the publication of his notices in due form and at the proper time and place, but must produce evidence that he is a person of good character; and in view of the probability of opposition, he also, as a rule, deems it prudent to produce a memorial or petition to the effect that the licence for his shop is desired in the neighbourhood. Having run this gauntlet and obtained the magistrates' permission to hold his licence or licences, he has to apply to the Inland Revenue Commissioners for the licences sanctioned. A grocer may obtain licences, all or any, for (1) the sale of beer and porter for consumption off the premises; (2) the sale of wine off the premises; (3) the sale of spirits off the premises. In 1906 the Excise Duty (annual) for the off beer licence was £1 5s.; the off wine licence £2 10s.; and for the off spirit licence an amount *ad valorem*, according to the value of the premises. This latter licence permits the licensee to hold off beer and wine licences without further payment of duty.

**Regulation of Premises.** The grocer holding any of these licences is bound to obey the provisions of the Licensing Acts so far as they apply to his particular case. He

has to be very careful, of course, as to the hours in which his premises are open for the sale of intoxicating liquor. In a town he must close at 11 p.m. and not open before 6 a.m.; in a village he must close at 10 p.m. On Christmas Day and Good Friday also his premises must be closed; and on Sundays there are special hours only on which they can be opened. If a grocer wishes to keep open his shop for the sale of groceries after the hour at which the law obliges him to close the sale of liquors, he is obliged to cover up the liquors in some way so that they are not "exposed for sale," as either exposing or selling them would cause him to incur serious penalties and risk the loss of his licence altogether. It is also very necessary to take care as to the quantity of liquors sold, this being a point minutely specified according to the licence held; and again as to the non-consumption on the premises; while if there be branches, the grocer has to take care that the orders are not accepted there (if they be not specially licensed), but merely forwarded to his licensed shop to be accepted or rejected there and the liquor appropriated there to the customer according to the order. Detailed instructions as to how to apply for and obtain the licences, and the law as to the points to be observed by licensees, such as are referred to above, are given in such trade annuals as "The Grocer" Diary.

**Shop and Window.** In the shop the fittings for an off-licence business need not be expensive—a few racks and shelves for bottles and a window or part of one. A few attractive shop and window bottle display stands are shown in the accompanying illustration [2]. The bottles should be displayed neatly and attractively and showards kept in evidence. If there is a cellar the greater part of the stock should be kept there; if not it has to be provided for in the shop as best may be. In that case bottles of wine should be stored as near to the floor as possible, to avoid unevenness of temperatures; and the bottles should always be placed on their sides and not standing up, as the corks of bottles of wines that stand up become dry speedily and the wine at once deteriorates. For this reason only empty bottles of wines and "dummies" should be used for a window display, the wine itself never being placed in the window. With regard to bottles of spirits, these can be used for the window or shop at will, and are better standing up than lying on their sides. Bottled ales and beer should also be kept upright. In passing, we may note that the legal term is "beer," which includes ale, porter, stout, spruce beer, black beer, or any other description of beer which contains a greater proportion than two per cent. of proof spirit. Even herb beer, ginger beer, hop ale, etc., are deemed to be beer, and come under the licensing laws if on analysis they are found to contain more than that amount of alcohol; so that small shopkeepers are sometimes fined for dealing in such "intoxicating liquors."

**Cellar Storage.** The cellar should be bricked round, with concrete floor, cool and

well ventilated so that the air shall be pure, but free from draughts. It should be kept clean and sweet by giving walls and ceiling a good coat of limewash at least once a year, and having the floor swept and sawdusted nightly. A little chloride of lime mixed with the sawdust is desirable in summer. In a cellar the great desideratum is an even temperature. Beers keep best at a fairly low temperature; about 55° to 60° F. is found suitable for cask and bottle alike. Port wine does best at about 58° to 60° F.; lighter wines at a rather lower temperature. For stands and bins iron is best. Casks should be placed horizontally, a few inches above the ground, on what are called gaunttrys, which are best made of solid concrete or framed double battens. Those gaunttrys with legs are not desirable, as the cask should be as rigid as possible. When sawdust is put down in the cellar see that it is not allowed to become damp and to stay in that condition.

#### Treatment of Beer.

When a cask of beer is received it should be placed on the gauntry in a position with just sufficient cant to allow all the hops to settle in the bulge of the cask and to allow the beer to be drawn off clear by the tap-hole. Then, with a large gimlet bore a hole in the highest part of the cask just behind the bung and in a line with it. In this place a vent-peg or "spile." This peg should be eased out carefully each day to allow the gas generated in the cask to escape, and then replaced; but care should be taken not to leave it out so long as to let the beer get flat. Beer brewed in March or October usually improves in quality, and keeps better after bottling if allowed to rest at least six weeks on the gauntry before bottling. Summer-brewed beer should be bottled off as soon as the beer becomes bright, which is in ten or fourteen days.

**Treatment of Spirits.** Brandy, rum, and whisky are not allowed to be sold (except as "diluted spirits") at a strength lower than 25 under proof—i.e., they must contain 75 per cent. of proof spirit. Gin may be sold as low as 35 under proof, though a good gin should be 20 under proof. ("Proof" means the strength of spirit as ascertained by Sykes's hydrometer; and by weight "proof" consists of 49.24 parts of alcohol and 50.76 parts of water.) In cask, spirits are often sent out considerably stronger than the above figures indicate and may, therefore, be "reduced" by

the retailer, who adds to them water as required, taking care that he does not bring the strength below the legal limit. Tables for "reducing" will be found in such trade handbooks as the "Wine Trade Review" Whisky Guide.

**Treatment of Wines.** Wines in the wood require very careful treatment, being very sensitive to any change of temperature. The cask should be placed on the gauntry as nearly horizontal as possible, in order that the "lees" may collect in the centre of the cask. The "lees" is the solid matter which is held in suspension, and by depositing which the wine clears itself. Sharp changes of temperature disturb the wine and cause the lees to rise again. For this reason, to prevent the lees

mixing again with the cleared liquor, the process of "racking" is resorted to—that is, the clear wine is drawn off and transferred to a clean cask. When this fails to clear wines they may have to be filtered and "fined," by the use of isinglass or white of egg, etc., as to which directions are given in various trade handbooks.

#### Profits of Licensed Branch.

It goes without saying that in the licensed branch of the grocery trade, as in any other, profits run according to the amount of skill the shopkeeper is called upon to exercise in handling his goods.

As indicated above, the business can be conducted in different ways: (a), as an agent, with a minimum of trouble; (b), buying goods in bulk and retailing one's own brands; (c), as a full-blown wine and spirit and bottled beer merchant, keeping a fully-stocked cellar and handling a large stock both wholesale and retail. The profits will naturally be in proportion — small

for (a), where little risk is taken and small skill required; larger for (b), in which both elements are increased; largest for (c), where the greatest expert knowledge and highly trained skill are required and brought into play. In the space at command we can hardly pretend to teach the whole art and mystery of judging vintages, blending spirits, and so on. But it may be useful to note that even (b) as a mode of conducting the licensed trade shows substantially better results than (a), the simplest form of that trade. Thus, the bottling of wines may show 25 or 30 per cent. profit on returns, instead of less than half that percentage. To *brew* beer for sale, we may note, a special licensee is required, and duty has to be paid upon the beer itself.

2. SHOW STANDS AND BRACKETS FOR BOTTLES

# HEALTH AS CAPITAL

Nature and Production of Vital Force. Causes of its Variation in Amount. Preservation and Expenditure of Our Strength. Health Paupers

By Dr. A. T. SCHOFIELD

IT is necessary to inflict one more financial chapter on the reader in order to bring home to him the real analogy there is between health and wealth. There is indeed amongst a vast number of the population more than an analogy, there is an actual substitution of the one for the other, for there are numbers of working men, who form the very backbone of their country, whose *only* wealth is their health, and who can, therefore, so well understand the terms here used, seeing that their daily vital force is their sole income, their reserve of health their sole capital. How important, therefore, it is that the working man should understand how to take care of the one, and to rightly spend the other. Though a sound practical knowledge of personal hygiene is essential to all, it is of far the most value to those who know *no other wealth than health*, and to whom its loss is nothing less than a calamity, and spells bankruptcy in every sense of the word. We have spoken already in general terms of health finance; we will now consider the question of *capital and income*.

**Capital.** Capital is the reserve force that constitutes sound health. A hand-to-mouth existence without capital is not consistent with a healthy life. A person who leads such a life is absolutely dependent from hour to hour on the food he takes, without which he would utterly collapse. This is not health; for while a strong man requires food, he is not dependent upon it in the same way at all. The author had before him, for instance, the other day, a brisk, energetic man, over 5 ft. 9 in., and weighing under 8 st. He came to consult about some special symptoms of nerve trouble, but otherwise was in what he called "good health." Here, then, was a man with no capital, dependent from hand to mouth on his food force—one walking gaily along the edge of the precipice, who *might* walk there safely for some time, but who, on the other hand, *might not*, for the smallest push from any sudden disease would assuredly send him over. There are many such, making a brave show with practically no capital. On this reserve force or capital, then, depends the duration of our happiness and health.

**Life Force.** The next point is to understand a little more about our life reserve force. As regards *length of life*, this depends, as we have seen, upon heredity, and can be roughly calculated, but the *amount* of life force depends upon ourselves.

The period of growth is the real time when it is being stored, for although force at this period is largely spent in building up the body, it is produced so rapidly that capital is quickly accumulated. During adult life it can also be stored

more slowly until forty-five or fifty; but from that time it is spent a little faster than it is made, and is gradually used up in old age as income, until when a person dies a natural death hardly a (health) shilling should be left in the bank. Those who die prematurely die with much unspent capital, which is wholly wasted. Of course, the need for storing up capital in youth shows as nothing else does the importance of avoiding a drain on our resources at this time by youthful excesses; for there is no doubt whatever that a fast life is a short life and an unhealthy one, and not only can the store we accumulate thus be quickly dissipated, but the life itself ends in a premature bankruptcy. Our stock of vitality in relation to length of life is strictly limited, and though we may slightly prolong it by care, we can much more easily shorten it by excess.

Although we have given a table to calculate roughly the *duration* of life force, we know no way of computing its *volume* or amount during life. We can, of course, tell practically when it is running short, because our cheques are not honoured, but returned marked "No assets." In other words, we are easily tired in body and mind, and cannot recuperate as we should do.

**The Body's Many Systems.** Let us now touch on another point concerning capital, and for this we must cease to regard our personality as one, and look at ourselves as a community of seven or eight systems—the nervous, locomotor, digestive, circulatory, secretory, respiratory, reproductive, etc., each with its own banking account and its own separate capital, which, moreover, *cannot be transferred*, save quite exceptionally, from one account to another.

Thus, if a man has spent all his respiratory force, he really cannot make it up from any other system. If his nerve capital has run out, it is little consolation that his locomotor account shows a strong credit balance. He cannot transfer his reserve of respiratory food to an exhausted digestion, nor can the bankruptcy of a worn-out heart be averted because the secretory system is solvent.

The total health of the individual is, of course, made up of the reserve capital of the different systems; but the bankruptcy of an important system may mean the death of the man; or, if the ruin is only partial, his ill-health at least.

**Reserve of Nerve Force.** We shall point out the different values of the various capital funds, and, above all, the pre-eminent importance of nerve reserves. Health, and even strength of body, are really valueless if there be no nerve force to spend it; and while, on the one hand, we must fail if our heart capital be all spent, we can often live a long time if the nerve system be solvent, though many

other systems be well-nigh bankrupt. Of course, capital has a different importance at different times. The reserves in the vaults of the Bank of England might almost as well not be there in specie for perhaps fifty-one weeks of the year; it is on the fifty-second, when the run on the bank comes, that they have all their value.

**Inroads of Disease.** And so it is with multitudes around us. Numbers are what Sir B. Ward Richardson used to call the *morituri*, or those liable at any time to death, simply because theirs is a hand-to-mouth existence. We have given an example of such an one. Others are doing very well, because the times are quiet and healthy; but let a sudden run on the bank come in the shape of struin or shock, and the bank breaks at once; whereas, on the other hand, if the reserves are strong, the drain of minor diseases is hardly felt at all, or they pass us by as too strong even to be attacked. Banknotes owe all their value to the solid reserve of specie in the vaults, and are worthless without it; and that health which does not rest on a solid reserve of force in each of the various systems of the body is only like so much paper currency.

One last thought before we leave this general survey of capital. It is of the utmost importance in any run on the bank, in sickness of any sort, not only that it should be promptly met, but that the excess of capital paid out should, as soon as possible, be replaced; in short, that the man should not be content with the sickness being stopped; he must have his full health and strength restored. Hence the *supreme importance* of a thorough convalescence.

There are in health, as in wealth, *three classes* of people—those who *live beyond* their income, those who *live up to it*, and those who *do not spend it*. Before considering these classes, let us look for a moment at what in life represents *income*, as opposed to capital.

**The Daily Amount of Our Strength.** The average amount of food consumed by the average man at average work produces in or about 3,400 foot-tons of force daily. (A foot-ton is a ton raised 1 ft. high.) There is no need here for any greater accuracy, for what we want to understand is the principle on which we live, and not the exact details in figures.

Now, what is meant by the above? Let us briefly explain. To lift a ton, or 2,240 lb., 1 ft. off the ground requires a considerable amount of force. The combustion of food daily, combined with the oxygen we inhale, sets free from the service of the body daily 3,400 of such foot-tons. This force may be used as motion, heat, or in other ways. As a matter of fact, it is found that about nine-tenths of it is used unconsciously for the warming of the body, and for the maintenance of life, making good the wear and tear of the body, and manufacturing the various complicated products necessary for its existence, as, for example, a gallon of gastric juice and a quart of saliva daily.

This leaves us some 300 foot-tons of force still available for use consciously in any way that the will of the person pleases—in moving

the body about, including the tongue, as much or as little as we please; also in thoughts and emotions, which are expensive—in short, in living.

**Economical Expenditure of Force.** So that it appears that an average man in perfect health has a large income, of which, however, he can consciously control the expenditure of only about *one-tenth part*.

Considering this world for a moment as our school, we may say that an all-wise Creator puts into the hands of His creatures 300 foot-tons of force each morning as pocket-money—He meets all the school bills with the rest—and the way we spend it, wisely or foolishly, or hoard it, do good or evil with it, displays our character.

The income, then, of which we principally speak here is that tithe that is at our own disposal, and, as we have said, we may *exceed it, live up to it, or live below it*.

Those who exceed it are in danger, because to exceed income means to trench on capital—for in life there is *no credit* given, no getting into debt with others. We must pay our way, and if we get into debt, it can only be with ourselves by spending our principal, which is the way that leads to ill-health and death or bankruptcy.

Those who live up to their income and leave their capital untouched, are the wise, the happy, persons in perfect health; while those who live below it and try to save it, find that health cannot be hoarded, and that unspent income soon leads to ill-health, not through starvation, but plethora.

We must, then, be neither misers nor spend-thrifts if we would be healthy, but use wisely and well what is given us to spend, be it much or little; and while looking on health as well as on wealth as a good gift of God, we should never regard its accumulation as the object of life.

To spend the whole of life in acquiring health and strength, and to die without using the one or the other for any wise or useful purpose, is like amassing riches and having to leave them unspent and unused.

**Approximate Daily Expenditure.** But since living up to and not beyond our income—here set down at an average of 300 foot-tons—be such an advantage, is it not of the first importance to have some means of knowing whether we are doing so or not? Undoubtedly it is. But inasmuch as we cannot count our foot-tons as we can sovereigns in our pockets, we can only estimate our expenditure approximately.

If we spend what mental and physical force we have without strain each day, in order to produce a healthy fatigue of mind and body, which entirely disappears in sleep, so that we rise fresh and well; if we are conscious of no running down in weight or in our powers, especially of nerve force; if we have not to use any stimulants of any sort to keep up our energy, then we may justly believe we are not exceeding our income nor trenching on our capital. The man who habitually lives beyond his income needs stimulants, which, indeed, are but *drafts upon his capital* or reserve force.

But why should any live extravagantly since doing so can only bring disaster upon themselves?

## HEALTH

From several causes. In the first place, there is a large class of people who are in a distressing position through poverty, which obliges them to spend all their income in earning it; and even then, with all their efforts, they cannot quite earn what they are obliged to spend, and hence are perpetually overstepping their limits through sheer necessity.

**Health Paupers.** These form our large army of workers for their daily bread, who often find great difficulty in providing what are called the necessities of life—i.e., the 3,400 foot-tons the body requires for its maintenance. Indeed, their life is peculiarly hard, for the work they have to do is so arduous that they require far more foot-tons of force than the average man, and thus they fall short through insufficient food. We cannot call such people extravagant; they call for our sympathy and help, which can be best given by showing them how to economise force, and how most easily to generate it. Many thousands are in poor health, and many thousands die in consequence, because they live in such circumstances that good health cannot be maintained. They are obliged to become health paupers. But we do not write only for this distressed class, but also for those who, with a good income, often entirely provided for them without effort of their own, are free to spend it all, or nearly all, in any direction they please, and are at no time under the necessity of exceeding it. Why, then, should such ever be extravagant?

The motives, indeed, differ widely, though the results are the same. But although it is true that Nature takes no account of motives, and considers only the "what" and not the "why," and visits all extravagances with the same penalties, there is no reason why we should not consider them.

**Health Spendthrifts.** There are those who exceed their daily health income, as we have said; from a spirit of emulation or pride. They wish to show they are as rich and strong as others, and to such an extent will some go in keeping up deceptive appearances of being "grands" when they were never made for anything but "cottage" pianos, that, like the traditional "soldier" who lived on his pay, they "spend a half-crown upon sixpence a day." You will see a girl, with perhaps but 150 foot-tons of force for her daily pocket-money, emulating in all things her brothers, who have 300 or more to spend.

What would be thought of an engineer who drove his engine to double its power? The result would be the same as with a human being who spends double his health income—a complete breakdown.

Others are extravagant simply because their tastes and wants are expensive, and far beyond their income. Where fashion is concerned, for instance, all questions of health finance, if they ever exist, are forgotten; and if its votaries are required to live at high pressure through a London season, they are very near bankruptcy at the end; hence the almost universal custom with

such of a "cure" at some foreign spa in the autumn.

Many, through love of pleasure, fashion, or sport, or even from restlessness of disposition, are living at this extravagant rate, and make a great display of energy and health; all their goods, as it were, are in the shop window, without reserves behind.

Others, again, are extravagant from some fixed purpose for God or man. These set out quite prepared to suffer in health, even, if needs be, to lay down their lives in fulfilment of their call or mission.

As we have said, the reasons for extravagance differ immensely morally, but physically the result is the same. To God the motive is everything, to Nature nothing. The vicious man of pleasure and the overworked missionary both pay the penalty if they make reckless drafts on capital.

**Live Cheaply and Naturally.** Of course, the cheapest way to live is to live easily, and well within the limits of exhaustion. Fatigue is good, exhaustion bad. Life is so largely a matter of habit and temperament that many live healthily and wisely in a way that would kill others. We know one doctor who does all his hard study between half-past five and half-past seven in the morning, going to bed, of course, soon after nine, for the rule against burning the candle at both ends is one of the few that are well-nigh universal. Early rising, however, by no means makes all men either "healthy, wealthy, or wise." Many can work much more economically and easily at night than in the morning; all depends not only on the individual, but on the character of the daily occupation. That life is easiest that is most in harmony with our environment.

On the other hand, what does spend force with wasteful rapidity is hard work under severe mental shock, or when weak bodily, after some severe illness or under great pressure without sufficient rest or change. Working really "against the grain" is nearly always expensive. All forced labour is unhealthy.

Sudden changes of surroundings or occupation are often fraught with danger, and many men can no more bear transplanting after a certain age than some trees. Habit counts for so much.

We cannot overrate the importance, if there be a strain, of putting it always on the strongest and not on the weakest parts of the body. If, for instance, the brain is strong and the heart weak, do more head work, and less paid manual labour, and so on.

There is one form of spending which only makes us the richer and stronger in the practice. There is an income that only grows as it is spent, which we can never exhaust. It is well indicated in a book called "In Tune with the Infinite"; and the principle of it is simplicity itself. Once we are really in touch with a source of infinite energy and love, we can *give, give, give*, and be none the poorer. In the sphere of spirit life, at any rate, we are free from the care of ever being beggared.

*Continued*

# RAILWAY CONSTRUCTION

Considerations in the Inception of a Railway. Potential Earning Powers and Costs of Construction and Maintenance

Group 11  
CIVIL  
ENGINEERING

21

continued from page 2880

By R. W. WESTERN

**T**HE objects for which railways have sometimes been built are very diverse, and include military and political objects. Many railways in Russia and other parts of Europe and in India have been constructed with a single eye to the movement of troops in time of war. Other railways, of which the Canadian Pacific Railway is an example, have been initiated, if not maintained, to effect or consolidate the political union of the countries or provinces through which they run. The Uganda Railway has been built to introduce civilisation into that part of Africa, and in numerous instances, particularly in British India, there are railways the construction of which would have been indefinitely postponed, if not utterly abandoned, had it not been for the necessity of providing work for a famine-stricken population.

All these examples of railway building, though their existence should be borne in mind, are in their nature exceptional. The main object of railway building is to supply a commercial need in return for a commercial recompense. The great majority of railways are built with this object alone, and there are no railways, even among those referred to, which have not been built with a careful regard to this end.

**What a Railway is.** A railway may be regarded from more than one point of view. Considered merely as a physical entity, it may be defined as a roadway adapted for the exclusive use of vehicles provided with flanged rails. This definition would also include street railways, or what we now call *trams*. A railway as understood in this country is confined to ways with rails raised above the level of the ground. A railway may also be regarded as an economic organism; and this is an aspect that must never be lost to view, since upon the success or failure of a railway as an economic organism its expansion or decadence as a physical entity depends. Economically considered, a railway is simply one of the numerous organisations necessarily evolved by all civilised communities for the purpose of carrying its members and their goods.

If successful, it will develop and expand as the numbers and wealth of the community grow, and its success will depend upon the efficiency with which its functions are performed in competition with other railway organisations and with different forms of locomotion.

**Competition.** When once it has been ascertained that a district affords sufficient traffic to justify the construction of a railway, there is no other consideration of such far-reaching importance as that of the competition which may immediately or ultimately arise.

The profits to be derived from a commercial undertaking can under ordinary circumstances never exceed greatly that of the usual return from other enterprises of like standing, since if the profits are much higher, competitors will be attracted to its particular sphere of activity, and thus tend to reduce the profit to a more usual level.

Exceptions occur when the enterprise is in some way protected from competition, whether by law or from physical causes.

When the line of an existing railway occupies the only feasible route between two or more centres of population it is protected by physical causes from the competition of other railways, and, to a great extent, from the competition of other forms of land locomotion. In default of an only feasible route, if a railway occupy the best possible route which the topography of the country affords, a great measure of protection will be secured. By this it will be seen how important it is, in fixing the line of a new railway, to discover and decide upon one which is not merely good enough, but as nearly as possible the best.

**The Land Occupied.** The ground over which a railway runs is for ever spoiled for any purposes other than a road. This is one of the serious risks of railway enterprise. In almost any other kind of commercial undertaking the land purchased can, in the event of failure, be sold without any great loss of value. Even a canal may be converted into a railway. Many have been so converted. But a railway cannot be converted into a canal. The possession of land gives to the railway—that is, to the railway organisation—occupying it, the rights of a landlord in the monopoly of its use. Such rights unmodified would afford a very strong protection against competition of all sorts. But since the land required for a railway is a long thin strip which it would in almost every case be impossible to acquire without the assistance of the Legislature, the authorities, in granting the necessary powers, are always able to stipulate for such modifications as may seem necessary for the protection of the public.

**Concession or Act of Parliament.** The legal enactments enabling the construction of railways are treated in **PARLIAMENTARY SURVEYING** [page 1237].

It is sufficient to point out here that the terms of the concession necessarily exercise a very important influence upon the general plan and details of construction and equipment. The maximum rates for passengers and for the various classes of goods are usually fixed, together with a number of physical quantities, among

which the most important are the gauge, or width of the road, the greatest permissible gradient and sharpness of curve; the minimum distance at which the trains may be allowed to pass buildings, signal posts, and other trains; the lowest height at which the line may pass over public roads and rivers, &c. Such stipulations may, and often do, materially restrict and hamper the engineer in his choice of expedients.

**Nature of the Organism.** An undertaking of the magnitude and national importance of a railway can very seldom be the work of one individual, but must in practically every instance be done by the public for the public. Certain members of the community will specialise themselves for the purpose, devoting as shareholders a part of their property to carrying it out, or, as employees, their time and labour to carrying it on. Others, as customers, will contribute some of their means in order to participate in the benefits it affords.

The ordinary form in which the revenue account of a railway appears shows how the services rendered and the sacrifices made by the different groups of persons are balanced one against the other, of which we give a condensed summary:

## REVENUE ACCOUNT.

| Dr.                       |           |                  |   |  | Cr.      |
|---------------------------|-----------|------------------|---|--|----------|
| Wages and materials ..    | £ 582,000 | Traffic Receipts | £ |  | 964,000  |
| Dividends and Interest .. | 382,000   |                  |   |  |          |
|                           | £964,000  |                  |   |  | £964,000 |

The *traffic receipts* are contributed by customers. *Wages* (and if the railway be great enough to mine and manufacture for itself, the item *materials* also) are the remuneration of employees, while *interest and dividends* are the recompense of those who have sacrificed their property for the construction or development and expansion of the railway.

**The Working Ratio.** The ratio of the wages and material to the traffic receipts, obtained by dividing the former by the latter, is called the *working ratio*, and is usually presented as so much per cent. The working ratio in the present instance is 60 per cent., a very usual figure in Great Britain.

The following is a list from the principal countries for which railway statistics are available of the working ratios that obtain in each instance:

|                          | Per cent. |                  | Per cent. |
|--------------------------|-----------|------------------|-----------|
| Australia ..             | 68        | Holland ..       | 66        |
| Austria-Hungary ..       | 65        | Ireland ..       | 62        |
| Belgium ..               | 61        | India ..         | 44        |
| Canada ..                | 64        | Italy ..         | 75        |
| Cape Colony and Natal .. | 71        | Roumania ..      | 59        |
| Dutch Indies ..          | 57        | Scotland ..      | 54        |
| England and Wales ..     | 63        | Spain ..         | 47        |
| France ..                | 62        | Switzerland ..   | 57        |
| Germany ..               | 65        | Turkey ..        | 50        |
|                          |           | United States .. | 65        |

It will be seen that this most important relation is a very variable quantity. In the language of elementary algebra we may say, if  $R$  represent the traffic receipts of a railway—i.e., the amount shown on the right-hand side of the revenue account, of which an example is given above—and  $X$  and  $E$  represent the amounts of the two groups of items brought together on the other side of the account, in the order given, then  $R = X + E$ , since the two sides of the account must balance.

The working ratio, to be represented by  $\eta$ , then becomes equal to  $\frac{X}{R}$ , and  $\frac{E}{R} = 1 - \eta$ , where  $E$

represents the net earnings. But it has been shown that  $E$ , the recompense for investment of capital, tends, under the influence of competition, to become a proportion thereof approximating to the rate of return upon capital invested in other business of equal standing.

This tendency may be exhibited by actually equating the two, and we have  $\frac{E}{C} = \frac{J}{100}$ , where

$J$  is the per cent. of the rate in question, or the value of money for commercial purposes in the country at the period considered. Multiplying

both sides of this equation by  $\frac{R}{E}$  we obtain

$$\frac{R}{C} = \frac{J}{100} \cdot \frac{R}{E} = \frac{J}{100} \cdot \frac{1}{1 - \eta}$$

Thus, the very important quantities  $R$ ,  $C$ ,  $J$ , and  $\eta$  constantly tend towards values the relation of which is conveniently expressed by

the equation  $\frac{R}{C} = \frac{J}{1 - \eta}$ , where  $\eta$  as well as  $J$  is expressed in per cent.

In Great Britain, as a whole, the working ratio has risen from under 50 per cent. during the sixties to over 60 per cent. at the present time, this change being in a great measure accounted for by the diminished value of money, as above explained.

**Cost of Construction.** Before going further, it will be desirable to form some idea as to the cost of a railway. Anything from £4,000 to £60,000 or even £100,000 per mile, though true, is rather too vague for our purpose. It is important that anyone engaged in railway work, immersed in detail—as, of necessity, he usually is—should retain a clear vision of the cost of the whole, as well as its objects and function, in order that he may not be at fault in estimating the value and the relations of his particular part.

$$£ \times \text{lb.} + 10 \times \text{lb.}$$

is a formula easily remembered and applied. The symbol  $\text{lb.}$  here represents the number of pounds avoirdupois which one yard of the rail used will weigh, and the symbol  $£$  the number of pounds sterling that the rails cost per ton delivered.

This quantity doubled will give approximately the least cost of the permanent way of a single line of railway per mile of open line in sovereigns. The formula is not intended for practical use, but merely to fix ideas. The *permanent way*

includes the rails, the chairs which support the rails, the sleepers to which the chairs are fixed, the broken stone or ballast upon which the chairs are laid, together with the bolts and other fastenings, for main line and sidings.

The *earth work*—the cuttings and embankments upon which the permanent way is laid—together with the necessary bridges, etc., will cost in a moderately undulating country about the same, and the necessary buildings and other works a similar amount. The minimum of equipment—*i.e.*, the engines and vehicles—will probably come to less, say

$$\frac{2}{3} \{ (lb. \times £ + lb. \times 10) \}$$

But the cost of obtaining the necessary legal powers to build, and the expenses of acquiring the land, cannot be included in a general statement.

The approximation of the results of this formula to actual figures depends upon the fact that, in a well-designed railway, the weight of the rails per yard of length is to some extent a gauge as to the number and size of the sleepers taken, as well as to the amount and quality of the ballast beneath them; while the cost of the rails per ton delivered is a rough measure of the whole cost of the material utilised, as well as of the expense of doing the work. As a rule, the heavier rail is associated with a more level road, and therefore with more earth work.

According to the formula the permanent way of a single line of railway with 80 lb. rails at £6 per ton would be:

$$\begin{aligned} & 2 (80 \times 6 + 80 \times 10) \\ &= 2 (480 + 800) \\ &= 2 \times 1,280, \text{ or } \dots \text{£}2,560 \text{ per mile.} \\ &\quad \text{Earth work, etc.} \dots 2,560 \text{ " " } \\ &\quad \text{Other works} \dots 2,560 \text{ " " } \\ &\text{Total cost of road} \quad \text{£}7,680 \text{ " " } \end{aligned}$$

With 30 lb. rails it would come to about half, as the cost per ton would be rather more. Neither of these figures are very far from the average results of actual working.

**Estimation of Receipts.** The main factor in deciding the construction of a railway is the amount of its estimated annual traffic receipts. The cost of construction comes second, as this can be modified in various ways in order to deal with the greater or less amount of traffic.

Numerous formulæ have been invented for determining the receipts to be anticipated from a proposed railway, all of which, however, have but a local, or very restricted, application.

In settled countries the density of population, or the number of inhabitants per square mile, in the district through which it is to pass is the basis in every case. In new territories the estimate involves a further estimation as to the amount of immigration and probable commercial development.

In all cases comparison must be made with other districts as nearly like it as circumstances permit, and the estimate calculated on the

assumption that the local traffic receipts per mile of line will vary directly with the density of population and with the area served. The through traffic, which is derived from other railways, or the seaboard, etc., will usually be of a competitive character, and will depend upon the special facilities that can be afforded.

The chief difficulty consists in finding suitable subjects for comparison. The demand for railway accommodation depends chiefly upon the industrial development of the population. When a number of self-providing families occupy the land, there is little occasion for wholesale carriage except of passengers for pleasure. But where the land is occupied by numerous communities, each devoted to some special production, the materials for which and the results of which they exchange among themselves or with foreign countries for mutual consumption, a very high contribution per head will be made to the traffic receipts of the railways. The extent to which this specialisation of employment is carried is also dependent upon the density of population when other circumstances are similar; consequently the traffic receipts of an established railway tend to increase in a geometric ratio rather than in an arithmetic ratio to the density of population. Often the traffic receipts will be found to vary approximately with the density of population squared.

The method of estimating the probable traffic receipts of a railway by careful calculation of the output of mines and factories, etc., both actual and potential, accompanied by the detailed compilation of road statistics—*i.e.*, the number and character of passing vehicles—is extremely laborious, and no more certain than the foregoing method, since the amount of such traffic that can be diverted to a railway remains a matter of conjecture. It is, however, useful as a check upon the former.

**Working Cost.** It has already been pointed out that the establishment of a railway is the result of a public effort to provide a public service of locomotion. The effort is made in two ways. The first is measured by initial capital expenditure, and the second by the annual working expenses, the amount of which we shall now consider.

The chief thing to remember is that the whole aim and object of the first is to diminish the amount of the second. This point will be developed later. For the present purpose it is sufficient to note that every detail of the construction of a railway must be studied in respect to its influence upon the ultimate amount of working expenses, having regard to the kind of work—that is to say, the description of service—the railway is constructed to afford.

The railways of the United Kingdom began the present century—to take a conspicuous date—with a cash subscribed capital of almost exactly £1,000,000,000, which brought in a gross revenue of almost £100,000,000. Thus the figures of the combined revenue account for that year present themselves at once as percentages of the whole.

# CIVIL ENGINEERING

The expenses were as follow in thousands of pounds :

|   |               |
|---|---------------|
| Maintenance of way and works .. .. .                    | 9,540         |
| Locomotive power (including stationary engines) .. .. . | 19,288        |
| Repair and renewal of carriages and waggons .. .. .     | 5,173         |
| Traffic expenses (coaching and merchandise) .. .. .     | 19,348        |
| General charges .. .. .                                 | 2,459         |
| Rates and taxes .. .. .                                 | 3,757         |
| Government passenger duty .. .. .                       | 330           |
| Compensation to employees .. .. .                       | 146           |
| Compensation for personal injuries, etc. .. .. .        | 192           |
| Compensation for damage and loss of goods .. .. .       | 517           |
| Legal and parliamentary expenses .. .. .                | 306           |
| Steamboat, canal, and harbour expenses .. .. .          | 3,031         |
| Miscellaneous working expenditure .. .. .               | 648           |
| <b>Total working expenses .. .. .</b>                   | <b>64,735</b> |

These heads of expenditure are those prescribed by law for this country, and require some rearrangement before they can be turned to account for our present purpose. In the words of a well-known authority: "Rates and taxes and government duty we may best strike out altogether. They represent not so much an actual expenditure as a deduction from income. Compensation ought to come in where it belongs. Compensation to an injured plate-layer is properly part of the 'maintenance of way' expenditure; to an engine driver is part of 'locomotive power,' and so on. Parliamentary expenditure, if incurred in the promotion of a new line, is properly part of the capital cost of that line. If incurred in opposing a scheme believed to be contrary to the company's interest, it is a 'general charge'; or, in other words, is included in expenditure incurred, not in any special department of work, but for the benefit of the undertaking as a whole. Similarly, legal expenses should go where they belong. Fighting a claim for compensation for damage to goods is a necessary part of the cost of carrying goods; prosecuting for trespass on the line belongs to the expense of 'maintenance of way'; as would also litigation with, or drawing a contract with, a builder for station repairs, and so forth."

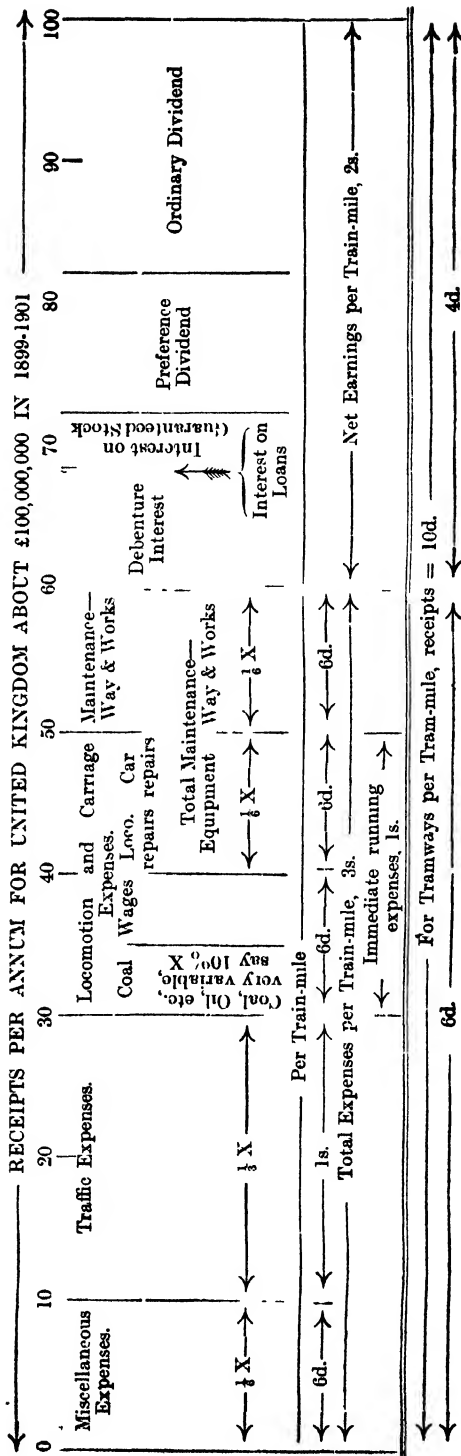

**Maintenance Departments.** The destination of the whole revenue of a railway company may be described as maintenance of one sort or another and grouped under four heads.

*Maintenance of Physical State* will comprise maintenance of the rails, fastenings, sleepers, ballast, earth work, bridges, culverts, fences, stations, signals, locomotives, carriages, waggons, etc.

*Maintenance of Traffic* will comprise the cost of running the trains, coal, wages of engine drivers, stokers, guards, porters, stationmasters, watchmen, signalmen, inspectors; cost of lighting, cleaning, stationery, etc.

*Maintenance of the Organism* will include the cost of co-ordinating the actions of the whole, and consist chiefly, of expenses incurred at the head office.

Thus, all the working expenses can be distributed under these three heads, while the net earnings, which, together with these, account for

the whole revenue, are devoted to the maintenance of the proprietors, who, after paying the interest on the debts of the undertaking, have the balance for their own enjoyment. And it is usually found that if the railway cannot adequately maintain its proprietors, its proprietors will cease adequately to maintain the railway. In the scheme on the preceding page, the expenses and earnings of an English railway have been separated out and divided into aliquot parts of the whole. This gives an arrangement of figures easily understood and remembered, as well as one that closely corresponds to average conditions, the adjustments needed to divide the expenses into equal divisions being very much smaller than the deviations found in actual working.

**Facts for the Constructor.** The business of the builder of railroads is chiefly concerned with those items of expense included under the headings, "Maintenance of way and works," and "Locomotive, carriage, and waggon expenses." The object of a railway is to reduce the cost of transportation. A heavy capital expenditure is incurred for this purpose. A railway is so efficient a means of doing this, that when originally introduced almost any construction might be a commercial success. In these days, however, the constructor must do his utmost to ensure that such work is done, and in such a way, as to reduce the cost of transportation in working to the lowest amount possible, having regard to the kind of traffic to be dealt with and the amount of the capital expenditure required to so reduce it.

The scheme presents also the items of expenditure in amounts *per train-mile*. The meaning of this is that the amounts in every case have been divided by the number of miles that have been traversed by the trains run during the period with which the accounts of expenditure deal. The object of presenting the items of expenditure in this form is to afford a convenient means by which the cost of working on different railways can be compared with one another.

**Running Expenses.** It will be seen that the actual cost of running a train one mile is approximately 1s., this being the average amount of the expenditure upon oil, fuel, wages of employees on the train, repairs to locomotive and vehicles. The cost of dealing with the train-load at each end of its journey appears as *traffic expenses*, and amounts also to an average of approximately 1s. The wear and tear to the railway itself and the works—i.e., buildings, etc.—that belong to it comes to about 6d. per train-mile. Adding to this the amount required to keep in repair and renew when necessary the vehicles and locomotive of the train itself, we

have once more 1s. on the average devoted to maintaining the whole plant of the organism in efficient physical condition.

**Physical Maintenance.** The cost of maintaining the railway, buildings, and plant is obviously in a different category to that of running trains and attending to traffic, of which the remaining expenses of a railway chiefly consist. The latter will depend upon competition and public demand to a much greater extent than the former.

Quickness in despatching parcels and goods, punctuality in trains of all kinds, comfort in passenger carriages, convenience at stations, are costly means of attracting traffic, but will not affect the item now under consideration. The cost that is incurred under it will, on the other hand, depend to a very great extent upon the solidity and workmanship of the structures, on their appropriateness to the purposes they were intended to fulfil, and the skill with which they were designed.

**The Minimum Conditions.** Before passing to the study of construction in detail, it may be well to point out the least conditions that must be fulfilled before railway construction of any kind is justified.

The expenses of keeping a railway of the lightest description in proper repair and its equipment in a state of working efficiency will amount at least to the average wages of one man for every mile of way open. The other expenses of dealing with traffic are not likely to be reduced to less than one-third of the receipts. The minimum value of  $X$  is not, therefore, likely to be reducible to less than  $w + \frac{R}{3}$  when  $w$  is the

average wages of an employé. Hence, if the estimated value of  $R$  is not greater than  $w + \frac{R}{3}$  by an amount sufficient to pay adequate interest on the capital required to build and equip the railway, the conditions will not suffice to justify construction at all, a railway is too ambitious a scheme, and humbler means of transportation must be adopted.

In Great Britain the minimum conditions are reached when the estimated receipts are no more than £1 per day or £360 a year per mile of line open to traffic. If the average wages of employees per head be as small as 25s. or £65 per annum, the total expenses might be brought down to  $65 + \frac{360}{3} = £175$ , which, deducted from £360, leaves £185 as net earnings, thus enabling, at 4 per cent., a capitalisation of £4,625 per mile, which is less than that of any light railway in this country would be unless built in very favourable circumstances.

By Amalia de Alberti

**Possessive Adjectives and Pronouns.** Possessives follow the rule of adjectives ending in o. They agree with the thing possessed, not with the person or thing possessing. They may be classed as possessive adjectives, and possessive pronouns.

POSSESSIVE ADJECTIVES.

These directly precede or directly follow the noun. They are as follow :

| Masculine.     |                 | Feminine.      |                                   |
|----------------|-----------------|----------------|-----------------------------------|
| Singular.      | Plural.         | Singular.      | Plural.                           |
| <i>mio</i>     | <i>mios</i>     | <i>mia</i>     | <i>mias</i> my                    |
| <i>tuyo</i>    | <i>tuyos</i>    | <i>tuya</i>    | <i>tuyas</i> thy                  |
| <i>suyo</i>    | <i>suyos</i>    | <i>suya</i>    | <i>suyas</i> his, her, its, yours |
| <i>nuestro</i> | <i>nuestros</i> | <i>nuestra</i> | <i>nuestras</i> our               |
| <i>uestro</i>  | <i>uestros</i>  | <i>uestra</i>  | <i>uestras</i> your               |
| <i>suyo</i>    | <i>suyos</i>    | <i>suya</i>    | <i>suyas</i> their, your          |

1. When *mio*, *tuyo*, and *suyo* precede the noun they lose their last syllable, and are the same for both genders, viz. :

|           |        |            |
|-----------|--------|------------|
| <i>mi</i> | plural | <i>mis</i> |
| <i>tu</i> | „      | <i>tus</i> |
| <i>su</i> | „      | <i>sus</i> |

2 The possessive adjective precedes the noun when no particular stress is intended. Examples : *mi padre*, my father ; *mi madre*, my mother ; *nuestra casa*, our house ; *sus tierras*, their lands.

3. As *su*, *sus* may mean either his, her, its, or their, the appropriate pronoun is added when there is any possibility of mistake : *su vida de él*, his life ; *su vida de ella*, her life ; *sus vidas de ellas*, their lives (f.).

4. Politeness demands this construction with *Vd*, even when there is no ambiguity : *su vida de Vd*, your life ; *sus vidas de Vds*, your lives.

5. *Vuestra* is used when the form of address is the formal *vos*, to one person, or the familiar *vosotros* to several. Examples : *Puedo imaginarme vuestra alegría á todas*, I can imagine how pleased you all were ; *Rogamos á Vuestra Majestad*, We beseech your Majesty.

6. The possessive adjective follows the noun in direct address (vocative case) : *Padre Nuestro*, Our Father ; *amigo mio*, my friend.

7. The possessive adjective follows an impersonal noun preceded by a definite article, for greater effect in poetry or oratory : *el alma tuya*, thy soul ; *la muerte mia*, my death.

8. With an adjective, the possessive adjective precedes or follows the noun according to the intensity of the meaning ; for instance, *Mi*

*querido amigo*, My dear friend, would be appropriate as the opening of an ordinary letter ; *Querido amigo mio* denotes more affection and familiarity, while *Amigo mio querido* might serve for the opening of a love-letter.

9. In phrases such as "a friend of mine," "neighbours of ours," the possessive adjective follows the noun : *un amigo mio*, *unos vecinos nuestros*.

10. The personal pronoun in the dative must be used with the verb and the definite article with the noun, instead of the possessive adjective, when referring to parts of the body or articles of dress : *Se quitó el traje*, She took off her dress ; *Me duele la cabeza*, My head aches.

POSSESSIVE PRONOUNS.

These are accompanied by the articles which agree with them ; they are as follow :

| Masculine.        |                     |                       |
|-------------------|---------------------|-----------------------|
| Singular          | Plural.             |                       |
| <i>el mio</i>     | <i>los mios</i>     | mine                  |
| <i>el tuyo</i>    | <i>los tuyos</i>    | thine                 |
| <i>el suyo</i>    | <i>los suyos</i>    | his, hers, its, yours |
| <i>el nuestro</i> | <i>los nuestros</i> | ours                  |
| <i>el vuestro</i> | <i>los vuestros</i> | yours                 |
| <i>el suyo</i>    | <i>los suyos</i>    | theirs, yours         |
| Feminine          |                     |                       |
| Singular.         | Plural.             |                       |
| <i>la mia</i>     | <i>las mias</i>     | mine                  |
| <i>la tuya</i>    | <i>las tuyas</i>    | thine                 |
| <i>la suya</i>    | <i>las suyas</i>    | his, hers, its, yours |
| <i>la nuestra</i> | <i>las nuestras</i> | ours                  |
| <i>la vuestra</i> | <i>las vuestras</i> | yours                 |
| <i>la suya</i>    | <i>las suyas</i>    | theirs, yours         |

1. The neuter possessive is the same as the masculine singular with the article *lo*, *lo mio*, etc. ; it has no plural.

2. Possessive pronouns lose their article when they stand as predicate of the verb to be. Example : *Esos guantes son mios*, Those gloves are mine.

3. But if particular emphasis is intended, they retain the article. Example : *Esos guantes son los mios*, Those gloves are mine.

**Demonstrative Pronouns.** There are three demonstrative pronouns which agree with the noun in gender and number, except the neuter forms, which are invariable :

| Singular.    |                |                |      |
|--------------|----------------|----------------|------|
| Masculine.   | Feminine.      | Neuter.        |      |
| <i>este</i>  | <i>esta</i>    | <i>esto</i>    | this |
| <i>ese</i>   | <i>esa</i>     | <i>eso</i>     | that |
| <i>aquel</i> | <i>aquella</i> | <i>aquello</i> | that |

|                   | Plural.          |       |
|-------------------|------------------|-------|
| <b>Masculine.</b> | <b>Feminine.</b> |       |
| <i>estos</i>      | <i>estas</i>     | these |
| <i>esos</i>       | <i>esas</i>      | those |
| <i>aquellos</i>   | <i>aquellas</i>  | those |

1. *Este* generally means something near the speaker, *ese* something near the person addressed, and *aquel* something at a distance from both.

2. The demonstrative pronoun regularly precedes the noun: *esta iglesia*, this church; *esa ciudad*, that city.

3. It follows the noun, which is preceded by a definite article in such sentences as the following, when the meaning may often be intensified in English by the addition of *here*: *los buenos amigos esos*, these good friends (here); *el hombre ese*, that man (there).

4. The definite article is also used as a demonstrative pronoun to signify *that*; it can often be rendered by the English possessive case. Example: *mi perro y el de mi hermano*, my dog and that of my brother (or my brother's); *nuestra casa y la de Vd.*, our house and yours (literally, *that of you*).

5. The neuter forms *esto*, etc., can never be used with a substantive; they have a thought, phrase, etc., for their antecedent. *Esto*, something said by the speaker; *eso*, something said by the person spoken to; and *aquello*, something referred to by either. Example: *esto es lo que me han dicho*, this is what I have been told; *eso no me importa*, I do not care for that; *aquello no fué verdad*, that was not true.

6. *Este* used substantively refers to the last-mentioned of two persons or things, and *aquel* to the first; *este* and its variations may, therefore, be translated "the latter," and *aquel* and its variations "the former." *Este*, *ese*, and *aquel* are also used substantively as *this*, *this one*, *that one*, etc. Examples: *¿quién es éste?* who is this (man); *el marido de ésta*, y *el padre de aquél*, the husband of this (woman) and the father of that (man).

7. The masculine and feminine demonstratives take an accent when used emphatically.

## EXERCISE VIII. (1).

Translate the following into Spanish:

- That overcoat is mine, and that dress is yours.
- These flowers are mine, these books are thine.
- I saved my life with a lifebelt.
- Thy hands are clean. Her face is pretty.
- Your life is laborious.
- God keep your Majesty.
- My friend, it is snowing; one cannot go out.
- My dear friend, I do not fear the snow.
- Some neighbours of ours have been killed by a thunderbolt.
- That child is ill.
- A sky rocket fell on that woman.
- Those clouds darken the sky.
- That is sea water.
- That man killed his brother—that is what they have told me; I do not believe it.

## EXERCISE VIII. (2).

Translate the following into English:

- No me importa lo que han dicho.
- Aquello que han dicho no es verdad.
- Eso es mío, es mi sombrero, y mi libro.
- Esos hombres son buenos.

5. Mi perro está en casa con aquel hombre.
6. Esta casa y esta iglesia son mías.
7. Esto es malo, y aquello es bueno.

KEY TO EXERCISE VII. (1).

1. El amor no se oculta.
2. Vd está enamorado de la hija de su vecino.
3. Si, señor, y se lo dije ayer.
4. Vd le es indiferente. No lo creo.
5. No tenga impaciencia; la paciencia es una virtud.
6. Una persona que odia busca venganza.
7. Esos son malos sentimientos, tenga bondad, y perdone.
8. El capitán, además de ser marino, es escritor.
9. El doctor de quien le habló es un especialista, pero no es un oculista.

10. Le han robado sus instrumentos de cirugía.

11. No tiene dolor de muelas, porque sus dientes son postizos.

12. El periodista es poeta, su periódico es un diario muy bien escrito.

KEY TO EXERCISE VII. (2).

1. He spoke to him, and he did not listen.
2. Give him the bread; I have given it to him.
3. Do you know this woman? I know her.
4. It is not true; I do not believe it.
5. He has hurt himself; call the doctor.
6. They have gone; call them.
7. It seems to me that he hates that man.
8. He met them in your house, and they fought.

## ITALIAN

used from  
c 20, 22

**Degrees of Comparison.** The qualifying adjective may be of three degrees: positive (*buono*, good), comparative (*migliore*, better), superlative (*ottimo*, best). The student will observe that the adjective given as an example is irregular in Italian as it is in English.

**COMPARATIVE DEGREE.** The comparative degree may be of three sorts: of equality, superiority, and inferiority.

1. THE RELATION OF EQUALITY is expressed in Italian by:

*così . . . come*, or *tanto . . . quanto*, as . . . as, so . . . as; *tanto, -a . . . quanto, -a*, as much . . . as, so much . . . as; *tanti, -e . . . quanti, -e*, as many . . . as, so many . . . as.

*Questa stanza è così grande come quella*, This room is as large as that.

*Noi abbiamo scritto tante lettere quante voi, ma voi non avete scritto tanto quanto noi*, We have written as many letters as you, but you have not written so much as we.

**NOTE.** In the forms *così . . . come*, *tanto . . . quanto*, *così* and *tanto* are generally omitted, so that the above examples may be written: *Questa stanza è grande come quella. Noi abbiamo scritto tante lettere quante voi, ma voi non avete scritto quanto noi.*

2. THE RELATION OF SUPERIORITY is expressed by:

*più . . . di*, or *più . . . che*, more . . . than. *Il ferro è più utile dell'oro*, Iron is more useful than gold.

*Quell'uomo è più morto che vivo*, That man is more dead than alive.

*Meglio tardi che mai*, Better late than never.

3. THE RELATION OF INFERIORITY is expressed by:

*meno . . . di*, or *meno . . . che*, less . . . than. *Noi siamo meno ricchi di voi*, We are less rich than you.

*Quella signora è meno bella di questa*, That lady is less beautiful than this.

*Più . . . che* and *meno . . . che* are used when the second of the two terms of comparison

## By Francesco de Feo

is an adjective, or a verb or an adverb. In many cases *più . . . di*, *meno . . . di*, and *più . . . che*, *meno . . . che* are equally correct.

The preposition *di* is coupled with the article according to the rules already given—e.g.:

*Mio padre è più vecchio di vostro padre*, My father is older than your father. In this sentence *di* must be used and not the compound article *del*, because the possessive *vostro* precedes the noun *padre*. [See the Possessive Adjectives, page 2771.]

*Questo libro è più utile di quello*, This book is more useful than that. In this sentence *del* would be incorrect, because *quello* is never preceded by the article. [See Demonstrative Adjectives, page 2632.]

*Il nostro giardino è più grande del loro*, Our garden is larger than theirs; here *del* must be used and not *di*, because *loro* always requires the article. [See the Possessive Adjectives.]

The comparison of superiority and inferiority may be strengthened by adding *molto*, *assai*, etc., to *più* and *meno*—e.g.:

*Mio fratello è molto più diligente di mio cugino*, My brother is much more diligent than my cousin.

*La vostra casa è molto meno comoda della nostra*, Your house is much less convenient than ours.

**NOTE.** The second of the two terms of the comparison of superiority and inferiority is often understood, as:

*La vostra casa è grande, ma la nostra è molto più grande (della vostra)*, Your house is large, but ours is much larger (than yours).

*Non ho mai visto un uomo più impudente (di Pietro)*, I never saw a man more impudent (than Peter).

*Quanto più . . . tanto più*, or *più . . . più* = the more . . . the more.

*Quanto meno . . . tanto meno*, or *meno . . . meno* = the less . . . the less—e.g.: *Quanto più leggiamo, tanto più impariamo, or più leggiamo, più impariamo*, The more we read, the more we learn.

EXERCISE XVII.

*fare* (fähreh), to make, to do  
*fa* (fah), it makes, it does  
*faceva* (fahchévrah), it made  
*farà* (fah-ràh), it will make  
*fa freddo*, it is cold  
*fa caldo*, it is hot  
*fa vento*, it is windy  
*passaggiata* (pahsseh-dgeeh-tah), walk  
*fare una passeggiata*, to take a walk  
*andare* (ahn-dàh-reh), to go  
*fedele* (feh-dèh-leh), faithful  
*ieri* (ee-eh-ree), yesterday  
*oggi* (òdgee), to-day  
*domani* (domàh-nee), to-morrow,

1. Pietro è buono come Carlo. 2. Io ho danaro quanto voi. 3. Mio padre è più ricco del vostro amico. 4. Quell' orologio è più caro di quella catena. 5. Il cane è più fedele del gatto. 6. L'inverno è molto più freddo dell' autunno, e la primavera è molto meno calda dell' estate. 7. Questo case sono più alte che larghe. 8. Ieri faceva freddo, ma oggi fa molto più freddo. 9. Se domani farà più caldo, andremo tutti a fare una passeggiata in campagna. 10. Questa strada è troppo lunga, l'altra è molto più corta.

**SUPERLATIVE DEGREE.** To indicate the highest degree of a quality the terminations *-issimo*, *-a*, *-i*, *-e*, are added to the last consonant of the adjective, as: *caldo*, *caldissimo*, hot, hottest; *puro*, *purissimo*, pure, purest.

The adjectives in *co* and *go* add the terminations *-issimo*, *-a*, *-i*, *-e* to the last consonant of their plural, as: *poco*, *pochissimo*, little, very little; *ricco*, *ricchissimo*, rich, very rich; *cattolico*, *cattolicissimo*, catholic, very catholic.

The adjectives ending in *io* drop both vowels before the terminations *-issimo*, *-a*, *-i*, *-e*; but if the *i* is accented, only the *o* is dropped, as: *savio*, *savissimo*, wise, wisest; *pio*, *piissimo*, pious, most pious.

**NOTE.** The Latin forms of some adjectives ending in *ico*—as: *magnifico*, *magnificentissimo*; *benefico*, *beneficentissimo*, etc.—are only used rhetorically. Some adjectives ending in *re*, *ro* retain in the superlative the Latin form in *erimo*—e.g., *cèlebre* (*chèh-leh-bre*), famous, *cèleberrimo*; *misero* (*meèsh-ro*), miserable, *miserrimo*; *salubre*, healthy, *saluberrimo*.

1. The **ABSOLUTE SUPERLATIVE** may also be formed by placing an adverb before the positive, as: *molto caldo*, very hot; *assai bella*, very beautiful; *estremamente buono*, extremely good; etc.

The superlative of some adjectives is also formed by placing *-arci* or *-stra* before the positive, as: *milionario*, millionaire, *arcimilionario*; *grande*, large, *stragrande*.

Another way of forming the superlative is to reduplicate the adjective, as: *lungo lungo*, very long; *corto corto*, very short; etc.

2. The **RELATIVE SUPERLATIVE** is formed by placing the article before the comparative degree of the adjective.

The relative superlative may be of superiority, and is then expressed by *il più*, *la più*, *i più*, *le più*, the most; or of inferiority, and is expressed

by *il meno*, *la meno*, *i meno*, *le meno*, the least—e.g., *Pietro è il più diligente scolaro della scuola*, Peter is the most diligent pupil of the school; *Carlo è il meno ricco di tutti*, Charles is the least rich of all.

If the adjective comes after the noun preceded by the article, it is better not to repeat the article: *lo scolaro (il) più diligente*. But the article is necessary before *più* and *meno* if the noun is preceded by the indefinite article, as: *un uomo il più cattivo*.

The following adjectives, besides the regular, have also a comparative and superlative of Latin form:

*alto*, high; *superiore*, superior; *supremo* or *sommo*, supreme, very high.

*basso*, low; *inferiore*, inferior, lower; *infimo*, the lowest.

*buono*, good; *migliore*, better; *ottimo*, the best.

*cattivo*, bad; *peggiore*, worse; *pèssimo*, the worst.

*grande*, great; *maggiore*, greater; *màssimo*, the greatest.

*piccolo*, little; *minore*, less; *minimo*, the least.

Pronounce: *àhl-to*, *soopèh-reeò-reh*, *sooprèh-mo*; *bàhssò*, *eenfèh-reeò-reh*, *cèn-feemo*; *boo-òno*, *mee-leò-reh*, *òtteemo*; *cah-tèè-vo*, *peh-dgeò-reh*, *pèhsseemo*; *gràhn-deh*, *mah-dgeò-reh*, *màhsseemo*; *peèccòlo*, *meenò-reh*, *meenèemo*.

For *migliore*, *peggiore*, and *minore* in familiar language may be also used the adverbial forms *meglio*, *peggio*, *meno*: *Le peggio cose for le cose peggiori*, the worst things.

*Il maggiore*, *il minore*, etc., mean also the elder, the eldest, the younger, the youngest; *il fratello maggiore*, *la sorella minore*.

In familiar language a few substantives may also assume a comparative and superlative, as: *più asino*, *asinissimo*, *servitorissimo*, *padronissimo*.

EXERCISE XVIII.

*mùsica* (modseecah), music  
*pàgina* (pàh-dgeenah), page  
*stòria* (stòreeah), history  
*spesso* (spèhssò), often  
*speso* (spèhso), spent  
*ferro* (fèhrro), iron  
*acciaio* (ah-chee-àheeo), steel  
*soddisfatto* (dì), satisfied (with)  
*studiato* (stoo-dee-àhto), studied  
*rimedio* (reemèh-deeo), remedy  
*male* (màhleh), evil  
*tanto meglio*, so much the better  
*tanto peggio*, so much the worse  
*vi piace?* (vee pee-àhcheh), do you like?  
*mi* (mee) *piace*, I like  
*è meglio*, it is better

1. Questa musica è bellissima. 2. Dante è il più grande poeta d'Italia. 3. Questa è la più bella pagina della nostra storia. 4. Il più grande debito è un beneficio ricevuto. 5. I poveri sono spesso più felici dei ricchi. 6. Se avete speso tutto il vostro danaro, tanto peggio per voi. 7. L'acciaio è più duro del ferro. 8. Noi siamo molto soddisfatti dei nostri studi. 9. I ragazzi hanno studiato tutto il giorno. 10.

Tanto meglio, più studiano, più imparano. 11. E meglio non parlare di certe cose. 12. Quella ragazza è bellissima; ha gli occhi neri neri e i capelli biondi come l'oro. 13. Mio fratello minore è in collégio; egli è un ragazzo intelligentissimo; è il migliore di tutti gli scolari. 14. Vi piace il mio vestito nuovo? 15. Non mi piace tanto, è troppo chiaro; il mio è molto più scuro. 16. Io abito (I live) molto lontano, ma il nostro amico abita molto più lontano. 17. Spesso il rimedio è peggior del male.

KEY TO EXERCISE XVI.

1. Fifty francs. 2. Fifty-one horses. 3. Here is the laundress's list: shirts twenty-one, collars forty-one, handkerchiefs eleven. 4. A pound sterling is five and twenty francs. 5. At

FRENCH

continued from  
page 2626

III. From the PAST PARTICIPLE are formed all the COMPOUND TENSES by adding it to the respective tenses of the auxiliary *avoir* or *être*.

| DONNÉ        | FINI            |
|--------------|-----------------|
| j'ai donné   | j'avais fini    |
| REÇU         | VENDU           |
| j'aurai reçu | que j'aie vendu |

IV. From the PRESENT INDICATIVE the IMPERATIVE is formed by omitting the personal pronouns. In the first conjugation the final *s* of the second person singular is dropped. The imperative has no third persons of its own, but borrows those of the subjunctive:

| INDICATIVE.   | IMPERATIVE.   |
|---|---|
| 1. <i>tu donnes</i><br><i>nous donnons</i><br><i>vous donnez</i>    | <i>donne</i><br><i>donnons</i><br><i>donnez</i>     |
| 2. <i>tu finis</i><br><i>nous finissons</i><br><i>vous finissez</i> | <i>finis</i><br><i>finissons</i><br><i>finissez</i> |
| 3. <i>tu reçois</i><br><i>nous recevons</i><br><i>vous recevez</i>  | <i>reçois</i><br><i>recevons</i><br><i>recevez</i>  |
| 4. <i>tu vends</i><br><i>nous vendons</i><br><i>vous vendez</i>     | <i>vends</i><br><i>vendons</i><br><i>vendez</i>     |

Exceptions:

1. Third Conjugation:

| INDICATIVE.  | IMPERATIVE.                                     |
|--|---|
|  | AVOIR   |
| <i>tu as</i> , thou hast<br><i>nous avons</i><br><i>vous avez</i>        | <i>aie</i><br><i>ayons</i><br><i>ayez</i>       |
|  | SAVOIR  |
| <i>tu sais</i> , thou knowest<br><i>nous savons</i><br><i>vous savez</i> | <i>sache</i><br><i>sachons</i><br><i>sachez</i> |

2. Fourth Conjugation:

| INDICATIVE.   | IMPERATIVE.                                  |
|---|--|
|   | ÊTRE   |
| <i>tu es</i> , thou art<br><i>nous sommes</i><br><i>vous êtes</i> | <i>sois</i><br><i>soyons</i><br><i>soyez</i> |

V. From the PAST DEFINITE the IMPERFECT SUBJUNCTIVE is formed, by changing *s* of

Marathon ten thousand Greeks under the command of Miltiades defeated a hundred thousand Persians. 6. In the last battle our enemies lost three thousand men. 7. We are at home on Wednesday and Friday. 8. The months of January, March, May, July, August, October, December have thirty-one days, February has twenty-eight, the others thirty. 9. The year has four seasons: Spring, Summer, Autumn, Winter. 10. Tarquinius Superbus was the seventh and last King of Rome. 11. At present my son has only two thousand francs a year, but in two or three years he will have almost (the) double. 12. Louis the XVI was beheaded in January, 1793. 13. It is half past eight and the train starts at five minutes past nine.

By Louis A. Barbé, B.A.

the second person singular into *sse*, *ssez*, *t*, *ssions*, *ssiez*, *ssent*. In the third person singular, the vowel immediately preceding the final *t* takes a circumflex accent:

| tu DONNA-S                   | tu FINI-S                    |
|------------------------------|------------------------------|
| <i>que je donna-ssse</i>     | <i>que je fini-ssse</i>      |
| <i>que tu donna-sssez</i>    | <i>que tu fini-sssez</i>     |
| <i>qu'il donnât</i>          | <i>qu'il finît</i>           |
| <i>que nous donna-ssions</i> | <i>que nous fini-ssions</i>  |
| <i>que vous donna-ssiez</i>  | <i>que vous fini-ssiez</i>   |
| <i>qu'ils donna-ssent</i>    | <i>qu'ils fini-ssent</i>     |
| tu REÇU-S                    | tu VENDI-S                   |
| <i>que je reçû-ssse</i>      | <i>que je vendi-ssse</i>     |
| <i>que tu reçû-sssez</i>     | <i>que tu vendi-sssez</i>    |
| <i>qu'il reçût</i>           | <i>qu'il vendît</i>          |
| <i>que nous reçû-ssions</i>  | <i>que nous vendi-ssions</i> |
| <i>que vous reçû-ssiez</i>   | <i>que vous vendi-ssiez</i>  |
| <i>qu'ils reçû-ssent</i>     | <i>qu'ils vendi-ssent</i>    |

1. **Special Remarks.** All prepositions but one require the verb which follows them to be in the infinitive. The single exception is *en* (in) which takes the present participle after it:

*Il joue au lieu de travailler.* He plays instead of working; *Il me regarda sans rien dire.* He looked at me without saying anything; *Après avoir lu la lettre il me la donna.* After having read the letter he gave it to me; *Les ouvriers travaillaient en chantant.* The workmen sang as they worked; *Elle nous regarda en souriant.* She looked at us smiling.

2. In English, "one," "ones" frequently take the place of a noun after an adjective. In French, there is no such construction, and the adjective alone must be used:

There are two books on the table, a large one and a small one, *Il y a deux livres sur la table, un petit et un grand*; Take the good ones and leave the bad ones, *Prenez les bons et laissez les mauvais*.

3. An adverb must never be placed between subject and verb. Its usual place is after the verb in a simple tense, and between the auxiliary and the verb in a compound tense:

I never see him, *Je ne le vois jamais*; He has never spoken to me, *Il ne m'a jamais parlé*.

4. An "if" clause must have its verb in either the present or the imperfect indicative.

With an "if" clause in the present, the "result" clause must be either in the present or the future indicative, or in the present imperative. With an "if" clause in the imperfect, the "result" clause must be in the conditional:

*S'il est ici, il doit nous voir*, If he is here, he must see us; *S'il est ici, il nous verra*, If he is here, he will see us; *S'il vient demain, nous le verrons*, If he comes to-morrow, we shall see him; *S'il est ici, qu'il vienne nous parler*, If he is here, let him come and speak to us; *S'il était ici, il viendrait nous parler*, If he were here, he would come and speak to us.

5. *Assez*, enough, always precedes the adjectives which it modifies:

*Le plus petit ennemi est toujours assez grand pour être dangereux*, The smallest enemy is always big enough to be dangerous.

|---|--|
| <i>le bout</i> , end, tip                                 | <i>le laboureur</i> , husbandman           |
| <i>la cause</i> , cause                                   | <i>le mal</i> , ailment                    |
| <i>le charançon</i> , weevil                              | <i>la maladie</i> , illness                |
| <i>le chef-d'œuvre</i> , masterpiece                      | <i>le mensonge</i> , falsehood             |
| <i>la chenille</i> , caterpillar                          | <i>la moisson</i> , harvest                |
| <i>la chose</i> , thing                                   | <i>la mouche</i> , fly                     |
| <i>le commencement</i> , beginning                        | <i>le nez</i> , nose                       |
| <i>la contrariété</i> , vexation                          | <i>le panier</i> , basket                  |
| <i>le crime</i> , crime                                   | <i>la perte</i> , loss                     |
| <i>le défaut</i> , defect                                 | <i>le point</i> , spot, speck              |
| <i>la dent</i> , tooth                                    | <i>la postérité</i> , posterity            |
| <i>envie</i> (f.), envy                                   | <i>la progéniture</i> , progeny            |
| <i>éléphant</i> (m.), elephant                            | <i>le rhume</i> , cold                     |
| <i>enfant</i> (m.), child                                 | <i>la ruine</i> , ruin                     |
| <i>ennemi</i> (m.), enemy                                 | <i>la sauterelle</i> , grasshopper, locust |
| <i>ennui</i> (m.), annoyance                              | <i>la ténuité</i> , tenuity, minuteness    |
| <i>la famille</i> , family                                | <i>le tour</i> , turn                      |
| <i>la fluxion de poitrine</i> , inflammation of the lungs | <i>la treille</i> , vine-stalk             |
| <i>la haine</i> , hatred                                  | <i>la vanité</i> , vanity                  |
| <i>importance</i> (f.), importance                        | <i>la verrue</i> , wart                    |
| <i>insecte</i> (m.), insect                               | <i>le vice</i> , vice                      |
| <i>la jalousie</i> , jealousy                             | <i>le voisinage</i> , neighbourhood        |
| <i>continuel</i> , continual                              | <i>le voisin</i> , the neighbour           |
| <i>dangereux</i> , dangerous                              | <i>le voleur</i> , thief                   |
| <i>durable</i> , lasting                                  | <i>insupportable</i> , unbearable          |
| <i>imperceptible</i> , imperceptible                      | <i>mortel</i> , deadly                     |
| <i>implacable</i> , implacable                            | <i>permanent</i> , permanent               |
| <i>indifférent</i> , indifferent, of no consequence       | <i>petit</i> , little, slight              |
| <i>indulgent</i> , indulgent                              | <i>pourri</i> , rotten, bad (of fruit)     |
| <i>innocent</i> , innocent                                | <i>seul</i> , alone, only                  |
| <i>arriver</i> , to arrive, come                          | <i>vilain</i> , ugly, nasty                |
| <i>causer</i> , to cause                                  | <i>gâter</i> , to spoil, decay (of teeth)  |
| <i>coûter</i> , to cost                                   | <i>mépriser</i> , to despise               |
| <i>craindre</i> , to fear                                 | <i>négliger</i> , to neglect               |
| <i>dépouiller</i> , to despoil, plunder                   | <i>réformer</i> , to reform, cure          |
| <i>à cause de</i> , because of                            | <i>aujourd'hui</i> , to-day                |
| <i>assez</i> , enough                                     | <i>bien</i> , very                         |

*ôien de (des)*, many  
*bientôt*, soon  
*contre*, against  
*d'ailleurs*, moreover  
*demain*, to-morrow  
*en herbe*, in the blade  
*en outre*, in addition  
*ensuite*, afterwards, then  
*malheureusement*, unfortunately

*presque*, almost  
*parmi*, amongst  
*quand*, when  
*quelquefois*, sometimes  
*sans*, without, but for  
*seulement*, only  
*sur nos gardes*, on our guard  
*toujours*, always.

#### TRANSLATE INTO FRENCH.

Those who despise small defects are very wrong. The smallest enemy is always big enough to be dangerous. It is not elephants that cause the loss of harvests and the ruin of husbandmen; it is locusts and little caterpillars, when the corn is in the blade; weevils and other imperceptible insects, when it is ripe. It is not big robbers only that despoil the vine-stalk and the orchard of their fruit; it is little ones also, sparrows and even flies. Without being deadly, little ailments are sometimes enemies as unbearable as the big illnesses of which we are afraid. It is almost always through little neglected ailments that the serious (great) ones come. To-morrow the little cold of to-day will perhaps be inflammation of the lungs. But for little defects there would not be any vices. Moreover, a little defect is not a slight thing, and where there is one, there will never be any masterpiece. A wart is not very big, but if you have it on the tip of your nose, it will be for you a continual cause of annoyance and of vexation. A small defect is never of slight importance if it is permanent. What is lasting is never slight. Moreover, a little defect is always the beginning of a big one; vices themselves are the children of little defects. The little defect will soon be great; where there was one there will soon be several. A little defect is never alone. It always has a family. If it is not for itself, it is for its posterity that it is to be feared. You have a tooth that has a little black spot. It is nothing; but, if you neglect it, it will soon be the whole tooth that will be decayed. After that one it will be the neighbour (f.), and then the neighbour's neighbour, and the little black speck that you have neglected will have cost you several teeth. If there is a bad plum in a basket of plums, all the plums will soon be bad. The neighbourhood of a little defect is never of no consequence. Vanity seems to be a slight defect; but it is a slight defect that has a very nasty progeny. It has for (its) son, falsehood, which, unfortunately, is not its only child. It has, in addition, two daughters, who are jealousy and envy. Amongst their posterity they will have hatred, which will, in (à) its turn, be the mother of many crimes. It is because of their very minuteness that little defects are so dangerous. If they did not look so innocent we should be afraid of them, we should be on our guard against them. Be indulgent towards (à) the little defects of your friends, if you are not in a position to cure them; but towards yours, which are always under your hand, be implacable.

KEY TO EXERCISE XXII.

1. A qui sont ces livres ? Ils sont à mon frère.
2. J'avais besoin de parler à votre père, mais il n'y était pas.
3. L'âne est sobre et patient ; il serait le plus beau des animaux domestiques s'il n'y avait point de cheval.
4. Les Gaulois étaient braves et robustes.
5. Le Maréchal Lannes avait été teinturier ; le Maréchal Ney fut tonnelier avant d'être soldat.
6. Le père du philosophe Diderot et celui de l'historien Rollin étaient couteliers.

7. Le pardon vaut mieux que la vengeance.
8. Les Romains ont été les maîtres du monde.
9. Il y avait une fois deux hommes qui étaient bien pauvres et bien malheureux.
10. Le premier était aveugle de naissance ; le second était paralysé.
11. Ils étaient l'un et l'autre (tous deux) incapables de rien faire.
12. L'aveugle, qui était robuste, porta le paralytique.
13. Le paralytique qui était doué d'une bonne vue dirigea son compagnon.
14. Seuls ils seraient morts de faim.
15. Unis ils furent à même de gagner leur vie.

By P. G. Konody and Dr. Osten

**LV. Comparison of Adjectives.** As in English, the comparison of superiority of quality, in monosyllabic and in many dissyllabic adjectives (also in participles and adverbs), is expressed by the addition of the suffixes -r or -er in the second degree or comparative, and -st or -est in the third degree or superlative. Examples : *breit*, bold ; *breit-er*, bolder ; *breit-est*, boldest. The *superlative* is either used attributively with the definite article (*der*, *die*, *das breit-este*, the boldest), and with the inflections of gender and declension ; or predicatively, preceded by the dative preposition *am* (3) with the corresponding termination of the dative. Examples : (attributive) *der breit-este Tisch*, the widest table ; (predicative) *der Tisch ist am (3) breit-esten* (dative), the table is the widest [among those compared].

1. In accordance with the rule of euphony the comparative adjectives and adverbs ending in -e have only -r added to the positive ; all others take -er. For the same reason adjectives ending in -el, -er, -en often cast off the -e in the comparative : *eitel*, noble, *et(e)l-er* ; *finster*, dark, *finst(er)-er* ; *offen*, open, *off(e)n-er* ; *verlassen*, dejected, *verlass(e)n-er* ; but the -e is retained in *befonnen*, considerable, *circumspect*, *befonnen-er*.

It must be remembered that the adjectives ending in -el, -er, -en, which cast off the -e in the comparative, retain this vowel in the superlative : *eitel*, vain, *eitler*, but *eitelst* ; *heiter*, merry, *heiterer*, *heiterst* ; *eben*, even, *ebener*, *ebenst*.

2. The *superlative* is formed by the addition of -st when the positive terminates in -d, -t, or in the hissing sounds -ß, -sch, -s : *rund*, round, *rund-est* ; *nackt*, naked, *nackst* ; *süß*, sweet, *süß-est* ; *merck*, brittle, *merck-est* ; *stolz*, proud, *stolz-est* ; in all other cases it is formed by the addition of -st : *fein*, fine, delicate, *fein-st* ; *langsam*, slow, *langsam-st*. The superlative of *groß*, great, *groß-est* (with modification of the vowel) is generally used in the shortened form *größt*—attributively *der*, *die*, *das größte*, and predicatively *am größten*.

In the case of many adjectives—especially monosyllables—the comparison is not only denoted by suffixes, but also by the modification of the vowel : *flug*, prudent, *flüg-er*, *flüg-st* ; *jung*, young, *jüng-er*, *jüng-st* ; *lang*, long, *läng-er*, *läng-st*. In compounds the same adjectives do *not* modify the vowel : *weitslug*, worldly-wise, *weitslug-er*,

*weitslug-st* ; *arm*, poor, *ärm-er*, *ärm-st* ; but *blutarm*, anæmic (also miserably poor, poor as a church-mouse), *blutärmer*, *blutärmst* ; *warm*, warm, *wärmer*, *wärmst* ; but *brühwarm*, boiling hot, *brühwärmer*, *brühwärmst*, etc.

In several adjectives both forms of comparison (with and without modified vowel) are employed alternatively : *bläß*, pale, *blässer*, *blässest*, or *blässer*, *blässest* ; *gesund*, healthy, *gesünder*, *gesündest*, or *gesunder*, *gesundest* ; but the comparative and superlative *without* modification of the vowel is generally preferable.

3. IRREGULAR COMPARISON. The comparison of the following adjectives is irregular :

- 1, *hoch*, high ; 2, *höher* ; 3, *höchst* (the *e* is omitted in the comparative) ;
- 1, *nahe*, near ; 2, *näher* ; 3, *nächst* (a *e* is added in the superlative) ;
- 1, *gut*, good ; 2, *besser* ; 3, *best* ;
- 1, *viel*, much ; 2, *mehr* ; 3, *meist* (the form "*mehrst*" is scarcely used) ;
- 1, *gering* (*wenig*), insignificant, little ; 2, *ger nger*, also *minder*, *weniger* ; 3, *geringst*, *mindest*, *wenigst* ;
- 1, *früh* (also *eh*), early ; 2, *früher*, *cher* ; 3, *früheist*, *cheft* (also *erft*).

4. The declension of the comparative and superlative follows the mode of declension of the positive.

5. The Comparison of Equality occurs when persons or objects whose qualities are compared are of equal standing. It is formed by the particle *wie*, like, as (denoting equality or similarity), preceded by the demonstrative particle *so* or *ebenso* (as or just as), which is placed before the adjective. The adjective naturally stands in the positive : *Ihre Augen waren so blau, wie der Himmel*, her eyes were as blue as the sky ; *mein Hund ist ebenso flug, wie der seinige*, my dog is just as clever as his. After *ebenso* the particle of superiority *als*, than, is also used, but *wie* is more correct.

6. In the Comparison of Superiority the conjunction *als*, than, is *always* used : *er ist fleißiger als ich*, he is more diligent than I. The two conjunctions used with the comparison of equality and superiority, *wie* and *als*, are very frequently confounded, even by Germans themselves.

The comparison of superiority is often intensified by the addition of such words as *viel*, much; *sehr viel*, very much; *bedeutend*, un'gemein, um ein Bedeutendes, considerably; etwas, something, somewhat; weit, bei weitem, far, by far; wenig, ein wenig, a little; am meisten, mostly; allerwenigstens, least, etc.

For reasons of euphony the adjectives terminating in -er, when used attributively, often form the comparative with *mehr*, more, etc.—for instance, the clumsy comparative of bitter: ein bitterer-er Geschmack, a bitterer taste, is replaced as in English by: ein mehr bitterer Geschmack, a more bitter taste; or by: ein Geschmack von größerer Bitterkeit (a taste of greater bitterness). For the same reason the clumsy superlative of adjectives ending in -isch is avoided by the use of *sehr*, very; *äußerst*, un'gemein, exceedingly; *höchst*, most, etc. Instead of the superlative of *schmeich'lerisch*, adulatory, cajoling—der *schmeich'lerischste*; or of *phanta'stisch*—der *phanta'stischste*, it is better to use the circumlocution: der *sehr* (ungemein, *höchst*, *äußerst*) *schmeich'lerische*, *phanta'stische*.

**LVI. Numerals** [see XXXII.]. The *Ordinal Numerals*, substantively or adjectively used with the definite, and sometimes with the indefinite article, are derived from the *Cardinal Numerals* [page 2050], and are formed by the suffix -te added to the numerals from 1 to 19, and -te to all others. Exceptions to this rule are the ordinal numerals of 1, eins, 3, drei, and 8, acht, which are formed: der erste, der dritte, der achte. Thus the ordinal numerals are:

|              |                |                |
|--------------|----------------|----------------|
| der erste    | der neunte     | der sechzehnte |
| der zweite   | der zehnte     | der achtzehnte |
| der dritte   | der elfte      | der neunzehnte |
| der vierte   | der zwölfte    |                |
| der fünfte   | der dreizehnte | der zwanzigste |
| der sechste  | der vierzehnte | der einund-    |
| der siebente | der fünfzehnte | zwanzigste     |
| der achte    | der sechzehnte | etc.           |

The ordinal numbers added to the names of kings, etc., are written in Roman figures without the article, as in English, but when pronounced the article must not be omitted: Die Frauen Heinrichs VIII. (the wives of Henry VIII.) is pronounced die Frauen Heinrichs des Achten.

The declension of the ordinal numerals follows that of the attributive adjective [see XXVI.]. They can be employed as such with the indefinite article and the case ending: der zehnte, the tenth, and ein zehnter.

**LVII. Derivatives of Numerals.** From the cardinal numerals are derived:

1. THE DISTRIBUTIVE NUMERALS, by use of the adverb je: je fünf, by fives; je zehn, by tens, ten of each. This form is also employed with ordinal numbers: je der erste, je der zehnte, implying the first, or the tenth, in each group. The distributive numerals are subject to declension.

2. REITERATIVES are formed by the addition of the substantive -mal (times): ein-mal, zwei-mal, drei-mal, etc., once, twice, thrice, etc.; and also in connection with the indefinite numerals viel, much; manch, some; kein, none; einige, several, a few. Examples: viel-mal, many a time, often; manch-mal, sometimes, fein-mal, never; einige-male, several times; alle-

mal, always; ein paar mal, a couple of times. When used as attributive adjectives, they are declined as such [see XXVI.].—e.g.: nach drei-malig-em Sturm-lauf, after three assaults [thrice undertaken]; das ein-malig-e Signal (weak, with the definite article), and ein-malig-es Signal (strong, without article) genügt, one signal [the signal once given] sufficed. Mal is also applicable to ordinal numerals: zum ersten, zweiten, dritten mal, etc., for the first, second, third time, etc.

3. MULTIPLICATIVES are formed by the addition of -fach, -fältig (or -fältig), -fold, indicative of multiplicity: zwei-fach, drei-fach, hundert-fach, hundert-fältig, etc., twofold, threefold, a hundred-fold, etc.; also with indefinite numerals: vielfach, vielfältig, mannigfaltig, mannigfach, many-fold. They are used as adjectives and declined.

4. VARIATIVE NUMERALS are formed by the addition of the suffix -erlei, which indicates variety, kind, etc.: ein-erlei, zwei-erlei, of one sort, of two sorts; and with indefinite numerals: viel-erlei, manch-erlei, mehr-erlei, all without declension and employed adverbially.

5. DISTINCTIVES are derived from the ordinal numerals by the suffix -ns or -ens (-ly): erstens, zweitens, drittens, firstly, secondly, thirdly, etc.

6. FRACTIONAL NUMERALS are formed by the suffix -tel, an abbreviation of the substantive Teil, part, added to the numerals from 1 to 19 (the t is dropped in 8: Acht-el; ein Drittel, one-third, is irregular) and -stel to the numerals from 19 upwards: ein fünf-tel, one-fifth; das Acht-el, the eighth; ein zwanzig-stel, one-twentieth. The bisection of one (1) is denoted by ein Halb (half): ein halb-es Huhn, half a chicken (used adjectively and declined); zweieinhalb Pfund, two pounds and a half. The division with halves can also be expressed by the direct amalgamation of halb with the ordinal numeral; two and a half can be denoted by dritt(e)halb, in the sense of three with half of the last unit missing; viert(e)halb, three and a half, etc. One and a half is expressed by anderthalb, ander (the other one) being an ancient word for "the second." Halb, half, and ganz, whole, when used as adjectives, are declined; the other fractionals add only -s in the genitive singular, and remain unaltered in all other cases. Halb never precedes the article, but must always follow it: eine halbe Stunde, half an hour; ein halber Tag, half a day; etc. Halb and Ganz take no article before geographical names: halb Europa, half Europe; ganz Amerika, the whole of America, etc.

**LVIII. THE INDEFINITE NUMERALS**, wenig, a little; viel, much; all, alles, all; ein paar, a few; einige, some, several; jeder, jeglicher, jedweder, everyone; mancher, many a; keiner, none; etliche, several, are used as substantives and as attributive adjectives, and are declined as such. But wenig, little, and viel, much, remain at times undeclined when used poetically: Viel Steine gab's (gab es) und wenig Brod'laib, literally translated: Much (instead of "many") stones there were and little (few) loaves of bread. Genug, enough; nichts, nothing; insgesamt, altogether; mehr, more; weniger, less, are not subject to declension. Weir, both, is declined like an adjective and is never followed by an article or pronoun: die

beiden Männer, both men, but never beide die Männer; meine beiden Söhne, my two sons, but not beide meine Söhne. Beide is also used substantively: Beide waren ehrliche Männer, both were honest men.

# EXAMINATION PAPER XV.

1. Which suffixes denote the comparative and the superlative in the comparison of superiority, and is there any difference in the suffixes thus employed in English and in German?
2. Which preposition must be used with the superlative of adjectives used predicatively? What is then the case of the adjective?
3. How does the consideration of euphony affect the comparison of superiority of adjectives ending in -el, -en, -er?
4. Which adjectives take the suffix -st in the superlative, and which only -st?
5. What rule concerns the formation of the superlative of adjectives ending in -el, -en, -er, which cast off the -e- in the comparative?
6. Which adjectives modify their stem-vowel in comparison, besides taking a suffix?
7. When do they not modify their stem-vowel?
8. Which adjectives are irregularly compared?
9. Which is the conjunction used for the comparison of equality, and by what other word is it generally preceded?
10. Which conjunction has to be employed for the comparison of superiority?
11. How do the rules of euphony affect the formation of the comparative and superlative of adjectives terminating in -er?
12. How are the ordinal numerals from 1 to 19 and from 20 upwards formed?
13. Which ordinal numerals correspond to the cardinal numerals 1, 3, 8?
14. Which additions to the cardinal numerals serve to form the distributive, reiterative, multiplicative, variative, distinctive, and fractional numerals?
15. What difference is to be noted in the use of the article with the fractional numerals halb, half, in English and in German?
16. What is the origin of the addition made to the cardinal numerals in the formation of the fractional numerals, and how is this suffix spelt in the numerals from 1 to 19 and from 20 upwards?

EXERCISE 1 (a). Form the comparative of the following adjectives:

Der Tisch ist breit. Das Seil ist dick. Der Wein  
The table is broad. The rope is thick. The wine  
ist fein. Die Rose riecht herrlich. Wir kaufen  
is fine. The rose smells splendidly. We bought  
schöne Blumen. Er sah traurig aus. Der Himmel  
beautiful flowers. He looked sad. The sky  
ist düster. Der Baum ist kahl. Das Schloß war lose.  
is dreary. The tree is bald. The lock was loose.  
Mein Pferd ist edel. Mein Pferd ist von edler  
My horse is noble. My horse is of noble  
Abstammung. Er sandte mir einen süßen Beten.  
descent. He sent me a quick messenger.  
Ich sah ein schlankes Mädchen. Die Kerze brannte hell.  
I saw a slender girl. The candle burnt brightly.

Mein Papier ist weiß und Ihres ist gelb.

My paper is white, and yours is yellow.

Nette Leute findet man selten.

Nice people are rarely (to be) found.

(b) Transpose the following positives into the comparative and superlative:

Das Pferd läuft schnell. Die Sonne Italiens  
The horse goes [runs] swiftly. The sun of Italy  
scheint hell. Ich wohne nahe. Der Ton klingt  
shines brightly. I live near by. The note sounds  
rein. Das Kind lernt fleißig. Der Ballon  
pure. The child studies diligently. The balloon  
steigt hoch.  
rises high.

(c) Change the following positives into superlatives.

Dieses Kind ist eitel. Die Straße war eben.  
This child is vain. The road was level.  
Die Gesellschaft ist fröhlich und heiter. Der tiefe  
The company is gay and merry. The deep  
Brunnen war auch breit. Man muß vorsichtig sein.  
well was also wide. One has to be careful.  
Der Turm ist hoch. Das hohe Haus kostet viel.  
The tower is high. The high house costs much.

Ich habe das gute Pferd gekauft.

I have bought the good horse.

Der edle Wein schmeckt gut.

The fine wine tastes well.

(d) Fill in the missing words and suffixes.

Ich bin . . . größer . . . du. Ich bin größer . . . du.  
I am as tall as you. I am taller than you.  
Sie sind . . . . . liebenswürdig . . . Ihre Schwester.  
You are just as amiable as your sister.  
Sie sind liebenswürdiger . . . Ihr Bruder. Dieser  
You are more amiable than your brother. This  
Schüler ist weniger fleißig . . . jener, ebaldich er  
pupil is less diligent than that one, though he  
. . . . . alt ist . . . er. Das Haar des Mädchens  
is just as old as his. The hair of the girl  
war . . . . . ein Sternfeld. Das Haar des Mädchens  
was as fair as a cornfield. The hair of the girl  
war lighter . . . ein Sternfeld.  
was fairer than a cornfield.

EXERCISE 2 (a). Form the ordinal numerals of the following figures:

Ich war der 15 . . . in der Reihe. Der Offizier  
I was the fifteenth in the row. The officer  
las zuerst den 3 . . . Namen und dann den 8 . . .  
read first the third name and then the eighth.

Sharks and Rays. Sturgeons. Bony Fishes. Fishes as Parents. Lung Fishes. Lampreys and Hags. Lancelets, Sea-Squirts, and Acorn-headed Worms

continued from  
page 2002

By Professor J. R. AINSWORTH DAVIS

**FISHES** are aquatic, cold-blooded vertebrates, with a defensive armour of scales or bony plates embedded in the skin. They breathe throughout life by means of gills, which are delicate folds or filaments connected with openings (gill slits) in the sides of the throat. Flattened expansions of the body—i.e., fins—are present,

340. PIKED DOGFISH

A. Dorsal fin B. Tail fin C. Pelvic fin D. Pectoral fin  
Photographed by Prof. B. H. Bentley

some of which, *unpaired*, are in the middle line, while others, *paired*, correspond to the fore and hind limbs of amphibians, etc. All the fins are supported by firm rods, the *fin-rays*.

**Classification of Fishes.** Four orders are recognised—namely, (1) **SHARKS and RAYS** (*Elassmobranchii*); (2) **END-MOUTHED FISHES** (*Teleostomi*), divided into the three sub-orders of (a) fringe-finned fishes (*Crossopterygii*), (b) sturgeons and their allies (*Ganoidei*), (c) bony fishes (*Teleostei*), including the most common forms—for example, salmon, cod, mackerel, eel; (3) **LUNG FISHES** (*Dipnoi*); (4) **LAMPREYS and HAGS** (*Cyclostomata*). The last two orders differ so much from the others that they are often considered as separate classes.

**Order 1. Sharks.** The sharks and their small allies, the dogfishes, are the typical members of this order [340]. The body is spindle-shaped, and well adapted to make its way through the water by wriggling movements from side to side. Propulsion is furthered by the largest of the unpaired fins—i.e., the caudal,

or tail fin, in front of which, on the upper side of the body, are two others of similar kind, the dorsals, which help to balance the fish in the water. The front pair of paired fins (pectorals) are capable of a certain amount of movement, and help in steering the course, while the hinder paired fins (pelvics) are subordinate aids to swimming.

The unsymmetrical shape of the tail fin is particularly noteworthy, and is well seen both in the illustration of a dogfish [340] and that of a porbeagle shark [341]. These creatures are chiefly ground-feeders, and when they swim forwards without steering this sort of tail enables them to move directly downwards to the sea floor, which constitutes their chief area of operations. But by appropriate movements of the pectorals they can also swim straight ahead or obliquely upwards as may be desired.

It is characteristic that in members of this order the mouth should be on the under side of the head, a somewhat inconvenient situation, since to seize its prey the fish is obliged to turn over on to its back. Five gill slits are visible on either side in front of the pectoral fin [342], and just behind the eye there is an aperture known as the *spiracle*, which is the opening of a gill slit that is losing its use as a breathing organ, and serves to conduct waves of sound to the internal organs of hearing possessed by these fishes [340 and 342].

342. HEAD OF SHARK

Showing (A) five gill slits

**Tough Skin and Flesh.** The skin of a shark or dogfish is extremely rough, owing to the presence of little bony structures, the placoid scales, which closely resemble teeth in nature. Indeed, near the edges of the jaws they gradually pass into teeth, which may be considered as evolved from modified scales—from which it follows that the possession of teeth by mammals, reptiles, and amphibia points to their descent from fish-like ancestors. Owing to the fact that the skin of a shark is full of sharp scales, it is capable of being used, under the name of "shagreen," for various polishing purposes. The skin is also used in the manufacture of a kind of leather employed for ornamental purposes.

341. SKELETON OF PORBEAGLE SHARK

A. Dorsal fin B. Tail fin C. Pelvic fin D. Pectoral fin E. Gill arches F. Eye G. Jaws

Sailors have long been in the habit of indulging in shark steaks, and the question has lately been raised as to whether dogfishes, the plague of fishermen, might not be used as food. The question can no doubt be answered in the affirmative, and, as a matter of fact, these fishes are often exposed for sale in some of our ports—Dover, for example.

**Rays and Skates.** These well-known fishes [348], rhomboidal in form, with a long, slender tail, are closely related to the sharks and dogfishes, with which they are connected by a series of transitional forms. They constitute an important article of diet. The edible part, from which "crimped skate" is prepared, consists of the triangular sides or "wings" of the body, which are no other than the enormously enlarged pectoral fins. Sharks, dogfishes, and skate alike, are "gristly fishes," their skeletons being mostly composed of gristle, commonly hardened by the deposition of salts of lime.

The eggs of these forms are large, owing to the presence of a great deal of nutritive matter (food-yolk). They are fertilised internally, and may either develop within the body of the mother or be laid in horny cases, known popularly as "mermaids' purses" [369 A and B.]

**Order 2. End-mouthed Fishes.** The name of this order is derived from the fact that, as a rule, the mouth has been shifted forwards to the front end, which is undoubtedly the most convenient place for it. The gill slits are protected by a flap, the gill cover or operculum, and the skeleton is more or less bony. A swim-bladder containing air is commonly present, its primary use being to help in balancing.

The three sub-orders must be considered separately.

(a) **Fringe-finned Fishes.** These ancient forms are so called because the paired fins are in the form of large paddles bordered by a membranous fringe supported by fin-rays. At a remote epoch of the earth's history they were represented by numerous marine types, but by pressure of competition were gradually driven into estuaries and rivers, and now only include two freshwater African fishes. These are the bichir of the Nile (*Polypterus*) [343] and the slender reed-fish (*Calamoichthys*) [372], which lives in the rivers of Old Calabar. These forms are covered by rhomboidal bony plates, the tail fin is rounded, and there is a series of little finlets, each supported by a strong spine in front, running along the middle of the back.

(b) **Sturgeons, etc.** Here are included a small number of primitive fishes inhabiting the fresh waters and estuaries of the Northern Hemisphere, and in many cases so dissimilar that they would not be grouped together if it were not for the evidence afforded by extinct forms. This clearly shows that they are the surviving remnants of what was once a dominant marine group, and owe their preservation to the fact that they have taken refuge in the waters of the land, where the struggle for existence is not so keen as in the sea.

We may employ the term "ray-finned" in describing these fishes, for the thickened bases of

the paired fins are largely absorbed into the body, so to speak, while their projecting parts are thin and supported by diverging fin-rays. The bony pike (*Lepidosteus*) of North America is clothed in bony armour, and its strongly toothed jaws are drawn out into a sort of narrow beak [350]. The widely distributed sturgeons are distinguished by the possession of a long snout, used apparently for stirring up mud in order to secure worms and other small creatures as food. The small mouth is on the under side of the body, as in sharks, to which another resemblance is afforded by the extremely unsymmetrical tail, in relation to the ground-feeding habit. Armour is sometimes entirely absent, or may be represented by large keeled plates, as in our only native form, the common sturgeon (*Acipenser sturio*) [346] sometimes to be seen in fishmongers' shops. The swim-bladders of European species are made into isinglass, and their hard roes are salted to be sold as caviare.

The bow-fin (*Amia*) of North America is not so archaic in appearance as the forms so far considered. The tail is rounded, and the body covered with thin flexible overlapping scales [354].

(c) **Bony Fishes.** This large and dominant group, which still appears to be on the up grade, includes the great majority of existing species, and represents the most perfect product of evolution, so far, along the fish line. It is true that sharks and rays (including something less than 300 species) are still flourishing, but the important forms now to be considered embrace no less than 7,000 species, in round numbers.

The distinctive characters of bony fishes can largely be explained as adaptations to swift and accurately directed swimming. Some of them will readily be appreciated by examination of a herring [355], trout [356], or mackerel. The body is shaped like a rounded wedge, somewhat flattened from side to side, and eminently suited for sliding through the water with the minimum of friction.

Friction is still further reduced by the covering of thin flexible horny scales, bathed in a slimy secretion. Propulsion is effected by lateral undulations of the body, the effect of which is greatly enhanced by the powerful tail fin. The cumbersome armour-plating of the more ancient types has of necessity been abandoned, though it has been reacquired by a few sluggish forms, and safety from foes is sought in speed rather than in defence. But as adequate support is required by the body and firm attachments for the powerful muscles, the loss of a strong external skeleton is fully compensated for by the presence of a very elaborate internal skeleton largely consisting of bone [357].

The task of supporting the body in the water is to some extent lightened by the presence of a swim-bladder situated immediately below the backbone, obviously the best position for maintaining the balance. This organ is in reality a pouch which grows out from the front part of the digestive tube, with which it may remain connected throughout life, as in the herring, or else get separated off, as in cod.

## NATURAL HISTORY

**Parachuting Fishes.** It is particularly interesting to notice that in these fishes the tail fin is externally symmetrical, so that in unsteered swimming the course is straight ahead. A remarkable exception is afforded by the flying fishes, where the forked tail is markedly unsymmetrical, but with a large lower lobe, clearly for the purpose of giving an upward tendency to undirected swimming [358]. And it is well known that these fishes, especially when pursued by their enemies, are in the habit of rising out of the water, and remaining for some time in the air, to which their enormous fore fins, used as parachutes—not as wings—offer a very large supporting surface.

There can be no doubt that backboneed animals were originally evolved in the sea, and it is therefore only to be expected that the organs of respiration and circulation in fishes should have become adapted to an aquatic life. Indeed, as we have previously had occasion to notice, the backboneed animals of the land have been obliged to grapple with the difficulty of modifying the fish type of circulatory organs to suit the exigencies of terrestrial life. Amphibians and reptiles have done this to some extent, but only birds and mammals have

356. TROUT

A. Gill cover B. Pectoral fin C. Pelvic fin  
Photographed by Prof. B. H. Bentley

completed the process, and it is to this fact that their success in life is due.

**Structure of Gills.** Anyone who takes the trouble to lift up the gill cover of a herring or other bony fish will at once see several comb-shaped aggregates of scarlet gill filaments, collectively presenting a large surface for the purification of the blood [366]. They are attached to narrow bony bars, between which are the gill slits. The course of the water used in breathing can easily be observed in an aquarium of goldfish. It is taken in at the mouth, passes through the gill slits over the gills, and thence to the exterior. The heart receives impure blood from all parts of the body, pumps it to the gills for purification, and from these it flows to all the organs.

Many points in the life histories of bony fishes are worthy of special study. The small eggs are fertilised externally, and in the large majority of marine species float on the surface of the water, though some of them—for example, those of the herring, are sticky and adhere to stones, etc., on the bottom.

355. HERRING

A. Pelvic fin B. Pectoral fin C. Gill cover  
Photographed by Prof. B. H. Bentley

In some of the shore fishes, such as the little blennies, they are enclosed in protective capsules [359]. The fry, or larvæ, which hatch out from the eggs are very unlike the adults in appearance, and have to pass through many changes before acquiring the characters of the species to which they may happen to belong [360]. Both eggs and fry are eagerly sought out as food by a host of enemies, but they are produced in immense numbers, so that extinction is prevented. The hard roe of a cod, for instance, has been calculated to produce over nine million eggs each season.

**Colouration.** The colouration of fishes is to a large extent protective, rendering them inconspicuous by harmonising with the surroundings. Seen from above, the darker upper side is confused with the dark sea-floor; seen from below, the white or pale under surface blends with the glimmering background caused by the penetration of light into the water; seen from the side, the "reversed shading" takes away from the appearance of solidity, as already described for many of the backboneed animals of the land. In many cases the colours change to suit different surroundings. During the spawning season some fishes, usually the males, assume bright courtship colours. The most familiar example is that of the little sticklebacks (*Gasterosteus*) of our inland streams [361], in which at this time the male (then known as a "robin") arrays himself in a scarlet livery, and is unusually pugnacious, fighting to the death other suitors who attempt to interfere.

**Care of the Young.** Parental affection among fishes is usually notorious by its absence. But to this there are some honourable exceptions, and in such cases fewer eggs are produced, for each has a better chance of hatching out into a larva destined to attain maturity. In one of the freshwater catfishes (*Aspredo*), for example, the eggs are attached to the roughened under surface of the mother's body.

357. SKELETON OF A CODFISH

A. Pelvic fin B. Pectoral fin C. Gill cover

Strange to say, however, it is to the paternal side that we must mostly look for examples of the care of eggs or young. The sticklebacks are well known in this connection. The male constructs a muff-shaped nest, made up of fragments glued together by a sticky secretion of the kidneys [361]. In this his wives lay their eggs, which he jealously guards till they hatch out, a procedure rendered necessary by the depraved cannibalistic tendencies of the females, and when the tiny fry emerge he protects them for some time. The male of the curious little seahorse (*Hippocampus*), which holds on to seaweeds by means of its curly tail, has a sort of pouch on the under side of the body in which the eggs pass through their development, and which serves as a city of refuge for the fry [345]. The same is true of the pipe-fish (*Syngnathus*), a related form [370].

Salmon and eels are curious instances of precautions taken for the benefit of the rising generation. It is a familiar fact that the former ascend rivers to spawn, the eggs being deposited in a sort of trench scooped out in the gravel or sand at the bottom. Exactly the reverse is true of eels, for it has been discovered of late years that they descend rivers to spawn in the deep sea, from which later on the little "elvers" return to the proper home of the species.

**Adaptation to Circumstances.** The great bulk of bony fishes resemble the herring and trout in shape, but there are, of course, considerable differences in detail, which may be illustrated by comparing the blunt-headed swordfishes [349]. There are also very considerable variations in the character of the fins, and even their number in the case of those which are unpaired. The original position of the hind fins (*pelvics*) appears to have been pretty far back [356], but there is a tendency for them to shift forwards, till in some cases they lie under the throat [357], being actually in front of the fore fins (*pectorals*).

But there are far more considerable deviations from the average type than those just mentioned. Sometimes the body is long and narrow as in pipe-fishes [370] and eels. In the former an advantage is gained when prey is being stalked on the sea-floor, for a body so shaped is very inconspicuous when seen from the front. The slimy cylindrical eel can easily wriggle through mud in the search for worms and molluscs. The seahorse (*Hippocampus*) [345], a fairly

358. FLYING FISH

near relative of the stickleback, is sufficiently remarkable. The long axis of the body is here directed upwards, and the head has been sharply bent down, as otherwise it would be in an unfavourable position for seeing and seizing food. This curious little fish is able to swim in a vertical position by the rapid movement of the dorsal fin from side to side.

**Methods of Securing Food.** Sometimes the head is of disproportionate size, as in some forms which are not good swimmers, but lurk under stones or elsewhere on the look-out for prey. The bullheads of our shores and streams are examples of this. A still more conspicuous case is that of the angler-fish or fishing-frog (*Lophius*) [364], which half buries itself in sand or mud, awaiting the approach of little fishes, which are attracted by a peculiar "lure" constituted by a much elongated fin-ray with a flap at the end. Such curiosity is commonly fatal, and there is no escape from the huge mouth

359. EGG CAPSULES OF  
BLENNY  
A. Enlarged360. WRASSE JUST HATCHED  
E. Yolk sack

with its long, sharp backwardly-curved teeth, which bend down to facilitate entry, but render exit

almost impossible. There are some deep-sea anglers in which the lure is phosphorescent.

Sometimes the body has acquired a rounded shape, as in the globe fishes (*Diodon* and *Tetrodon*) of tropical seas [353]. These are able to blow themselves up with air, and drift about back downwards, with their sharp spines erected for defensive purposes. The coffer-fish (*Ostracion*) also deviates from the normal type, and is further distinguished by its armour of bony plates [352].

A considerable number of bony fishes are flat in shape, the flattening being from side to side, not from above downwards, as in skates and rays. Some such forms—e.g., the John Dory (*Zeus faber*), swim with the body vertically disposed, and are likely to escape the notice of prey which happen to be in front of them; but the flat fishes par excellence (turbot, sole, plaice, etc.) are ground forms which, so to speak, lie down on the right or left side of the body, and either shuffle along or swim by undulating movements. In a plaice, for example, the dark surface of the body, mottled with orange spots, is not the upper but the right side [362], while the pale left

361. NEST OF STICKLEBACK

## NATURAL HISTORY

side [363] is directed downwards. It is obvious that the left eye, if retained in its proper place, would not merely be useless but liable to injury by friction against the sea-floor, and in the course of development it moves round the edge of the head on to the right side. To begin with, the young fish is symmetrical, and swims in the usual fashion, but gradually becomes lop-sided and takes to living on the bottom. It is then that the left eye shifts its position. In most flat fishes both eyes are on the right side, as in the plaice, but in turbot and brill they are on the left.

The most remarkable and weird-looking bony fishes live at great depths in the sea, and suggest dream visions caused by acute indigestion rather than matter of fact living beings. We give illustrations of stomias [365], malacosteus [373], macrurus [374], and saccopharynx [367]. They are extremely voracious, with huge mouths and business-like teeth, and their eyes are either very large or much reduced, sometimes indeed absent. Many are studded with phosphorescent organs, and without light of this kind, supplied by various creatures, the abyss of the ocean would probably be pervaded by the profoundest gloom. Probably these unfortunate creatures have been driven into the deep sea from shallower waters by the stress of competition,

### Order 3. Lung Fishes.

It may be taken as an axiom that in all cases where more or less impure blood is separated by a thin membrane either from air or from water in

which air is dissolved a certain amount of respiration will take place—that is to say, oxygen will diffuse into the blood, and the waste product, carbonic acid gas, will diffuse out of it. The swim-bladder of fishes offers an opportunity of this kind, for numerous blood-vessels run in its walls, and it contains air, or a mixture of gases, of which one is oxygen. It is well known that in the Polypterus of the Nile, the bow-fin of the North American lakes, and certain bony fishes inhabiting fresh water, breathing is

furthered in this way. The process has gone a stage further in the lung fishes, which are at present represented by three freshwater types, the insignificant remnant of a group that was once dominant in the sea, and would have become entirely extinct if some of its members had not taken to live in the waters of the land. These types are the eel-shaped mud-fishes of West Africa (*Protopterus*) and South America (*Lepidosiren*) [351], and a Queensland form

(*Ceratodus*) [344]. In all these the swim-bladder has been converted into a regular lung which returns purified blood to the heart. The African form lives in streams which are liable to dry up, and were it not for the possession of a kind of lung capable of breathing air would perish during the dry season; whereas it remains embedded in the mud in a torpid state till the rains return. They are eaten by the natives, who dig them

out of the mud. Enclosed in their covering of clay, they have been brought alive to this country.

The Queensland lung fish lives under somewhat different conditions, for its native rivers do not entirely dry up, but are reduced to a series of deep holes connected by mere trickles of water. These holes become so foul from decaying vegetation and dead fish that the possession of a lung is a vital matter, and if the *ceratodus* were not able to come to the surface and breathe air it would probably succumb.

### Order 4. Lampreys and Hags.

These eel-shaped forms are represented in Britain by the freshwater lamprey (*Petromyzon fluviatilis*), the sea lamprey (*P. marinus*) [374], and the marine hag-fish (*Myxine glutinosa*) [347]. All of these are jawless, and the mouth is in the middle of a sort of sucker, studded with horny teeth, some of which are

also present on a so-called tongue. By means of the sucker they attach themselves to living prey, scraping away the flesh with the tongue.

### PRIMITIVE BACKBONED ANIMALS

There are three chief features by which backboneed animals are distinguished—namely, (1) the central nervous system is tubular and situated near the upper side of the body; (2) underneath part or all of this a longitudinal supporting rod, the *notochord*, is present at

## NATURAL HISTORY

some time or other during life, being, as a rule, entirely or partly replaced by a backbone in the adult; (3) the throat is perforated by gill slits during part or all of life. If these characters are taken as tests the backbone animals include not only mammals, birds, reptiles, amphibians, and fishes, but also three other groups, the members of which are unfamiliar to all but specialists. These are: (1) LANCELETS (*Cephalochorda*); (2) SEA-SQUIRTS or ASCIDIANS (*Tunicata*); (3) ACORN-HEADED WORMS (*Hemichordata*), etc.

**Lancelets.** The Lancelet (*Amphioxus*) [375] is a little flattened animal some two inches long, of very wide distribution, and formerly considered as a primitive sort of fish. It is in possession of all three characteristics mentioned above, but, like the lampreys and hags, and all primitive backbone animals, is jawless. It is sharply pointed at either end, whence the name, and burrows in shallow water where the sea bottom is sandy. When feeding it is embedded in the sand in a vertical position, and water flows into its bell-shaped mouth, serving both for breathing purposes and also to convey the minute organisms which serve as food.

376. SIMPLE SEA-SQUIRT  
The arrows indicate the course of the water

**Sea-squirts.** Living in the sea, and attached to various objects, are a number of curious animals resembling in shape one of the wine-skins of ancient times, and covered by a tough protective investment [376]. There are two openings in the body, into one of which currents of water continually flow for feeding and breathing purposes, while waste products of all kinds are as continually swept out of the other. On dissection we find that the equivalents of gill slits are present, but there is nothing to represent a backbone, and the central nervous system consists of a little thickening between the two openings of the body, which is no help to classification. From the eggs of this curious creature, tadpole-shaped larvae [377] hatch

378. COLONIAL SEA-SQUIRTS

out, which satisfy all three of our tests except that the notochord is limited to the tail region. Later on they become attached, lose their tails and notochords, and at the same time the central nervous system becomes reduced. We have here, in fact, a good example of degeneration, due to the enervating influence of a fixed or sedentary life, which reduces the necessity

375. LANCELET (*Amphioxus*)  
A. Tail fin B. Mouth

for individual effort.

Many of the sea-squirts are colonial, consisting of a number of individuals connected together, and these may be either attached or free-swimming [378].

### Acorn-headed Worms, etc.

The best-known members of this small group are the acorn-headed worms (*Balanoglossus*) [379], which burrow in mud by means of the projecting front end of the body, which alternately elongates and shortens, the second process pulling the animal forward. A short elastic rod by which this region is supported possibly represents a notochord, while numerous gill slits are to be seen on the upper side of the body, and the central nervous system, though ill-developed, is situated as in typical

377. TADPOLE LARVA OF SEA-SQUIRT  
Gill slit b. Mouth c. Notochord

backbone animals.

These creatures are protected by a disagreeable smell, and are brightly coloured. The two sexes differing in this respect. They are, perhaps, the nearest living representatives of the ancestral stock from which all backbone animals have descended.

Unfortunately, traces of such soft creatures are hardly ever found preserved in the "record of the rocks," so that there is a good deal of scope for speculation.

It is a matter of great doubt which group of the innumerable backboneless animals, which we must next consider, comes closest to the backbone forms. There are, however, certain unsegmented marine worms (*Nemertines*), devoid of gill slits, notochord, and hollow central nervous system placed dorsally, but approaching backbone animals in some respects.

Henry III. and the War with the Barons. Welsh and Scottish Attempts at Independence. The First Prince of Wales. Beginning of the Hundred Years War

By JUSTIN MCCARTHY

**HENRY III.**, who succeeded his father, King John, in 1216, was born on October 1st, 1207, and was only a child when he became nominal ruler of England. The State affairs were managed meantime by a regent, but in 1227 Henry declared himself of age, and took the control of the realm into his own hands. He became engaged in a war with France, and, not getting the better of his opponent, might have come to severe loss had not the French sovereign, Louis IX., behaved with remarkable forbearance and generosity.

Henry was not an estimable sovereign. He was surrounded by favourites and parasites, and was sometimes reckless in the extortion of money to maintain his own prodigal expenditure. He did, indeed, adopt and proclaim the Great Charter, but he made his confirmation of it an excuse for obtaining a new money grant.

**The Barons' War.** The reign of Henry was made famous by the struggle known as the Barons' War. Henry's extortions and other caprices had exhausted the forbearance of the barons, whose Order held a constitutional position already, and in 1258 Parliament, led by Henry's own brother, Simon de Montfort, Earl of Leicester, rose against him, and enacted a series of statutes which they strove to make the King accept, and under which Henry was compelled to hand over his power to a commission of the barons. Henry kept terms for a short time, but disunion soon arose among the barons, and Henry took advantage of this to repudiate his contract and to break his oath. Then followed a struggle between the King and the barons, as a result of which, neither gaining anything that could be called a victory, the question was referred to the arbitration of the sovereign of France, who gave judgment in favour of Henry.

**Beginning of Representative Government.** But de Montfort was not content to let the matter end so easily. He collected his forces, and with the help of London and other English towns, he denounced the arrangement come to with the French King, attacked King Henry's army at Lewes, and captured Prince Edward, the King's son. Then it was arranged that the settlement of the country should take place under the control of three electors—Simon de Montfort, the Earl of Gloucester, and the Bishop of Hereford—by whose nomination nine councillors were to be appointed for the formation of a Ministry. In order that this should have the approval of the whole kingdom a sort of parliament was to be called together, in which, along with the barons and the prelates, there were to sit four knights chosen from each shire, and, for the first time in England's history,

two representatives from some of the larger towns. The whole system of our modern representative government in the House of Commons may be said to trace its origin from this definite attempt to construct a parliament.

**Death of Simon De Montfort.** The experiment scarcely came into actual organisation. The barons could not endure the supremacy of De Montfort, and King Henry, allying himself with some of them, took arms against Simon. Simon was defeated at Evesham on August 12th, 1265, and was killed on the field of battle. De Montfort was regarded by a large proportion of the people, and by the clergy in general, as a saint, and there are legends that miracles had been wrought by him. There was much in Simon's character which does not reconcile itself with modern ideas of sanctity, but he undoubtedly had the genius of a great constructive statesman, and foresaw the course which the constitutional development of Britain was destined to take.

Henry's reign lasted until 1272, when he died at Westminster. He was in a sense a fortunate sovereign—fortunate in the fact that his reign coincided with the opening of some great institutions which must ever be associated with England's advance in civilisation.

In his reign, although not by his inspiration, the first organised attempt to create a parliamentary system was made and, to a certain extent, carried out in England. By him, also, the first charter to the University of Oxford was granted. The belief that King Alfred founded the schools out of which the University grew is not now regarded by historians as other than a legend which naturally attached itself to Alfred's well-deserved fame. King Henry deserves credit for having encouraged the movement which led to the establishment of the Universities, but he cannot be regarded as the creating influence in that great development of England's national progress. The growth of the University of Cambridge goes back to the mythical period, and all that can be said of King Henry is that in the instance of Cambridge and of Oxford he gave his Royal sanction and support to the system. His name will probably be best remembered in history because of this and of the encouragement which he gave to the elevation of school teaching.

**Accession of Edward I.** Edward I. succeeded Henry in the natural course, for Edward was the elder son. He was born at Westminster, June 17th, 1239. On his marriage he received from his father the rulership of Gascony, Ireland and Wales. His earliest education in the business of war was received in Wales, where there was at the time much

disturbance. In the opening of the struggle against Simon de Montfort Edward took part with his father, but he afterwards lent his support to some of the conditions insisted on by De Montfort. He took part in the last crusade, distinguishing himself there as a knight, and it was on his return that he heard of the death of his father, which had taken place two months before.

**Edward's Foreign Policy.** When he returned to England, and had gone through the ceremony of coronation, he received the homage of the King of Scotland, Alexander III.; but it was remarked that Prince Llewelyn of Wales did not offer his homage until long after. It was then one of the institutions of the time that the rulers of Scotland and of Wales should be regarded as holding the crowns under the over-rule of the Kings of England. Edward was soon to be engaged in a war for the complete conquest of Wales, and its settlement as a part of the English Kingdom. The King afterwards proved that his principle of government was to give up altogether the idea of holding by force the foreign territories which his predecessors had won and had always struggled to maintain, and at the same time to devote all his energy and capacity to consolidating England, Scotland, Wales, and Ireland into one kingdom. The first task to be accomplished was the conquest of Wales. There had been continual risings in different parts of Wales against the authority of England, and when Edward I. succeeded to the throne these risings began to assume the form of a Welsh national movement.

**Last Struggle for Welsh Independence.** Llewelyn, the Welsh Prince, stood out against Edward and the army of the English sovereign invaded North Wales. The difficulties then to be encountered were too great for the Welsh resistance. Wales was divided into localities with separate chieftains, and it was hardly to be expected that all these should hold firmly together in support of a policy which might end in making them mere vassals of the Welsh prince if he should succeed in making his country independent of England. Llewelyn was defeated, and died on the field during a great battle in December, 1282. This defeat closed, to all intents and purposes, the struggle for Wales for independence.

Edward made on the whole a wise and generous use of his victory. He applied himself to establish trade guilds in the Welsh towns; to introduce the best forms of English jurisprudence into Wales; to divide the country into counties and shires, according to the methods prevailing in England, and to abolish some of the barbaric customs which still struggled against growing civilisation. The story that Edward ordered a massacre of the Welsh bards to prevent them from stirring up their people into another rebellion is now regarded as mere fable. The effect of his policy was, for the most part, satisfactory. The good relations between England and Wales did not remain undisturbed for ever after—in those days there were few countries in which domestic peace remained for long

unbroken—but no part of England's dominions gave her less trouble during the years to come than that which had been made part of Great Britain by the policy and the action of Edward I.

**The Dispute for the Scottish Throne.** Edward had a more severe struggle to encounter in Scotland. A dispute had arisen for the succession to the Scottish Crown on the death of the young queen, who had been betrothed to Edward's son, and this claim appears to have suggested to Edward the opportunity of setting up his own claim to the sovereignty of Scotland. The claimants to the throne of Scotland were Baliol, descendant of a great Anglo-Norman family, some members of which had held succession to the crown of Scotland for a long time, and Robert Bruce, Lord of Annandale, whose name is best preserved to fame by that of his grandson, Robert Bruce. Edward was invited to act as arbiter between the rivals, and he declared Baliol to have the higher claim.

Baliol was not long content with his position as subordinate to the over-rule of the King of England, however, and events gave him the opportunity which he was seeking. The French king, Philip IV., who had just begun to reign, made an effort for the recovery of all French lands from the English. Philip soon made open preparations for war. Thereupon the Scots, under Baliol, determined to take advantage of the chance thus offered to them, and there was soon war between the two countries. Edward invaded Scotland; Berwick was captured, but not without fierce resistance and much slaughter. The rest of the work, so far as that invasion was concerned, became comparatively easy. Edinburgh, Stirling, and other cities, opened their gates to the conqueror, and Baliol surrendered, and was consigned to an English prison.

**Battle of Stirling Bridge.** The real struggle, however, was yet to begin. William Wallace, the famous Scottish patriot, the descendant of a powerful Scottish family, made himself the leader of a movement against King Edward, which had purposes at once more direct and broader than those avowed by Baliol. Wallace went in for the complete freedom of Scotland from English dominion, and gathered around him a great force of patriotic followers. He defeated one of Edward's generals, the Earl of Surrey, in the battle of Stirling Bridge, and the whole Scottish kingdom then declared in favour of Wallace's leadership. The Scottish chief crossed the Border and carried the war into England, as far, at least, as Newcastle. He returned to Scotland, and was there proclaimed governor of the country in the name of King John, King John being the Baliol who had been unable to make his own Royal claims effective. The appointment conferred on Wallace was declared to be given by consent of the Scottish nation. King Edward was not a man to be easily put off any enterprise he had undertaken, and was, indeed, in the military sense, a foeman worthy of the Scottish hero's steel. Edward invaded Scotland with an army

of some 90,000 men, and Wallace, taken by surprise at this sudden and tremendous effort, was compelled to give battle whether he would or no, and underwent a total defeat at Falkirk. Wallace escaped to France, but did not remain there long. Returning to Scotland, probably in the hope of making some new effort, he was captured near Glasgow by one of Edward's Scottish governors, and carried a prisoner to London. There he was tried for high treason in Westminster Hall, found guilty, and sentenced to death in 1305.

**Execution of Wallace.** The sentence was carried out after a fashion which would now seem only worthy of a barbarous nation. The head of the illustrious Scotsman was cut off, and, having been derisively crowned with a chaplet of laurel, was set at the top of a pillar on London Bridge, while the body was disembowelled and quartered, the quarters being sent as a sort of warning to Newcastle, Berwick, Stirling, and Perth. Edward was generally inclined towards acts of mercy, and it is said in his defence that he was willing to show mercy if Wallace would have made some act of submission to his conqueror. But Wallace refused to make any submission, and stood up for his cause in the court where he was tried as he would have done on the battlefield.

Edward showed magnanimity in his manner of dealing with the Scottish people after he had got rid of Wallace. Some course had to be adopted for the reconstitution of Scotland under the new conditions, which no doubt Edward believed to be complete and lasting. A new form of government had to be arranged, and Edward entrusted the government of the country for the time to a council of Scottish nobles, several of whom had taken part in the war against England, but who were pardoned and invited to help in the re-establishment of peace and order.

Edward had in mind an entirely new constitution for Scotland, one principle of which was the representation of the Scottish people in the Parliament of England. This movement, however, did not come to any success. The longing of Scotland for actual independence was still fervid and unsubdued, and a man was soon to come to the front who could give it a more powerful expression. This man was Robert Bruce.

Edward did not live to see the more serious part of the struggle. He was in weak health, and was sinking into years, but he was making preparations for still another Scottish invasion when he died on July 7th, 1307.

**The First Prince of Wales.** He was succeeded by his son, Edward II., born in 1284, and in 1301 created Prince of Wales, the first heir-apparent to the British Throne who bore that now historic title. This first Prince of Wales had not in his early years given any promise of a successful rule; he had associated himself with unworthy favourites, one of whom, Piers Gaveston, acted in so lawless and shameless a fashion that the nobles of England rose against him, and demanded his banishment. When he returned to England, and endeavoured to regain

his former position, they compelled King Edward to assent to his execution.

Robert Bruce had sworn fealty to Edward I., and had even served in his army; but he joined the Scottish uprising under Wallace, and when that movement had ended, he appears to have accepted the new arrangements by which Edward I. endeavoured to bring about a final settlement between the two countries.

In those days, of course, the relations between England and Scotland were so unsatisfactorily defined, and even the boundaries between the English and Scotch realms, and between English and Scotch populations, were so indiscriminate, that the changes in the policy of a man like Robert Bruce are not difficult to understand. Bruce took a decisive course at last, and put himself at the head of Scottish resistance to England's overruling power. Bruce asserted his own right to the throne of Scotland, and was crowned King at Scone. The English Army entered Scotland in the reign of Edward II., and Bruce was defeated more than once. He had to take refuge on the north coast of Ireland, but afterwards returned to his own country, organised a new army, and, after the death of Edward I., in 1307, succeeded in driving the English forces out of most parts of Scotland.

**The Battle of Bannockburn.** On June 24th, Bruce encountered the English Army under Edward II. at the memorable battle of Bannockburn. The English Army is said to have amounted to 100,000 men; but Bruce, with an army of less than one-third in number, won a brilliant and complete victory. The military capacity of Bruce had made good preparation for this battle. He had drawn the English on to the spot where he could best confront them with his far inferior forces. He had dug the field with pits, which he carefully covered, and kept his own forces well drawn back. The English Army, who had to cross a broad stream to reach their enemies, fell into the pits, which caused so great confusion that Bruce and his soldiers were able to turn the defeat into a complete disaster. King Edward narrowly escaped with his life from the battlefield, and some 50,000 of his soldiers—at least half his army—were either killed or taken prisoners.

In 1317, Robert Bruce crossed to Ireland to assist his brother Edward, who had been engaged like him in the struggle for Scottish independence, and was invited by the chieftains of Ulster, the Northern, or Scottish province of Ireland, to accept the Irish Crown. He was crowned King of Ireland in 1316, and maintained his resistance to the English forces until his death on an Irish battlefield in 1318. The struggle between Robert Bruce and the English went on, after the battle of Bannockburn, until the Truce of 1323. On the accession of Edward III., in 1327, the Scotch invaded the northern counties of England, and it became evident to the English king that England's resistance to the national uprising of Scotland could no longer be maintained with any hope of success. The Treaty of Northampton, in 1328, brought the war to a close by England's recognising the independence of Scotland, and

the right of Robert Bruce to that throne which he had won by the force of his armies and by the indomitable devotion of his countrymen.

**The End of Robert Bruce.** Robert Bruce did not reign long. He died, in 1329, at Cardross Castle, on the Firth of Clyde, at the age of 54. To him life had indeed been worth living, for he had assured the independence of his country at a time when Scotland could not have counted on any enduring condition except by the terms of national independence. Bruce's body was buried in the Abbey of Dunfermline, and, according to his own desire, his heart was to be carried to Palestine and laid to rest within the sacred city of Jerusalem. The bearer of the heart, Sir James Douglas, commonly called the Black Douglas from his dark complexion, was one of Robert Bruce's most brilliant officers in the struggle for Scotland's independence. Douglas was killed in Andalusia on his way to the Holy Land in an attack made on him and his party by the Moors, and the heart of Bruce was brought back to Scotland and laid to rest in Melrose Abbey.

The latter part of Edward II.'s reign was marked by many calamities. There were risings in Wales and in Ireland as well as in Scotland, and there were seasons of famine and of plague. There were struggles against his rule even in England. Edward's last invasion of Scotland led to his having to accept the Truce of 1323. Then came a quarrel with Charles IV. of France, the brother of Edward's wife Isabella, who detested her husband, and actually turned against him under the influence of one of his disaffected nobles. Edward was made prisoner by this band of titled rebels against his power, and compelled to resign the crown in favour of his son Edward. But his resignation of the crown did not save his life, for he was murdered in Berkeley Castle on September 21st, 1327.

**Edward III.** Edward II. was succeeded by his son, Edward III. The reign of the young King began under the most unpromising and even appalling conditions. He came in for the succession of a still enduring hostility between England and Scotland, and for constant disturbances in Ireland and in Wales. At home there was widespread discontent caused by poverty, itself in great measure the result of extravagant expenditure on war, and in the suppression of frequent rebellions at home.

Edward III. was proclaimed King at the very time when his father was held prisoner in Kenilworth Castle, and the young King for a while refused to accept the throne offered to him without the sanction of his father. The supporters of the Queen and her party then went through a sham ceremonial to obtain the King's consent, and the hesitating son was prevailed upon to accept his new position. The young King was for the time a mere instrument in the hands of his mother and her supporters. He was still but a boy of fourteen, and a number of peers and bishops were appointed to act as a council of regency, to be the advisers and guardians of the sovereign during his minority. Most of the members of this council were under the

influence of the King's mother and her favourite, Mortimer, and Queen Isabella was therefore enabled to exert her own authority over the government of the realm without regard for the intentions of Parliament, which was already beginning to claim its rights as the representative of national opinion.

Troubles again arose with Scotland. After the death of Robert Bruce, Edward Balliol claimed the Scottish throne, and Edward III. came to his assistance and inflicted defeats on the opposing Scots, but could not bring them to submission. These disputes between England and Scotland were still going on when King Edward allowed himself to be drawn into hostility with France. The French king, Charles IV., died without leaving a son, and the nearest heir to the throne, Philip of Valois, was proclaimed sovereign as Philip VI.

#### **Battles of Crecy and Poitiers.**

Edward claimed the crown on the ground that his mother was a sister of the dead sovereign, and although the law of France did not allow a woman to succeed to the throne, Edward maintained that a woman's son might be the direct and lawful successor. This led to a war with France, and to Edward's invasion of that country. His first attempt was unsuccessful; but in 1346, accompanied by his eldest son, the famous Black Prince, he defeated the French in the memorable battle of Crecy. Not long after, the Black Prince accomplished the great victory of Poitiers, where the King of France, John II., son of Philip VI., who had died before the dispute about his right to the throne had ended, was taken prisoner. A peace was concluded, but as one of the conditions of King John's release from captivity was that he should pay a large ransom, which he found himself unable to do, the French King gave himself back to his enemies, and was taken to London, where he died in 1364.

The Scottish king, David II., had made a secret treaty with Edward by virtue of which the Scottish kingdom was to be handed over to the English over-ruler if David should die without a son. Thus, neither in Scotland nor in France did Edward secure any of the advantages for which he had fought so hard, and for which in France he had won two of the most brilliant victories known to history.

**Trouble at Home.** Edward with all his sagacity did not seem to be able to appreciate the fact that success on the battlefield and the infliction of defeat on foreign enemies will not always reconcile a sovereign's own people to the disturbance of commerce and trade, the discouragement of all profitable work, and the hideous spectacle of gaunt national poverty, brought about by the pursuit of the conquest of territory and the glitter of military fame. Edward began to find the work of government beyond his strength. The finances of the State were threatened with exhaustion, and civil government was falling into what seemed hopeless collapse. Edward became entangled in frequent disputes with his Parliament, and meanwhile gave himself up to demoralising influences, and made less and less effort to restore the

prosperity of the state. His third son, John of Gaunt, was left to look after the business of government. His eldest son, Edward the Black Prince, who had become an open opponent of his father's do-nothing policy, died on June 8th, 1376. The Black Prince, who is said to have derived that name from the colour of his armour, had distinguished himself in other campaigns as well as in the victories of Crecy and Poitiers. He is said to have acted with merciless severity in some of his conquests of captured cities; but generous and merciful dealings with the inhabitants of cities that had made a stubborn resistance was not common among the conquerors of those times.

The life of Edward III. did not last long after that of his eldest and most famous son. He died on June 21st, 1377.

### **The Birth of English Literature.**

Edward's reign will always be famous for its victories on the battlefields of France, but it will find a still higher title to enduring recollection in the fact that it saw the birth of genuine English literature [see LITERATURE]. Geoffrey Chaucer, the first of the great English poets, had written some of his greatest poems while King Edward was still living. He was the son of a tavern-keeper in London, and the date of his birth is not certain. Some writers give it as 1328, but the accounts which seem more authentic give it as 1340. In his youth he became a page in the household of the Duke of Clarence, and was afterwards raised to the services of the Royal Family. He served during one of the campaigns in France, was taken prisoner in Brittany, but was soon ransomed, the English sovereign contributing a part of the amount demanded. The King afterwards granted him a pension. He was sent abroad on several missions into Italy, Flanders, and France, and also held the post of Comptroller of the Customs in the Port of London.

**Gower and Wycliff.** Another poet who belongs to Chaucer's time, James Gower, was a personal friend of Chaucer's, but the fame of Gower is not so closely associated as that of Chaucer with the development of English literature, because some of Gower's poems are written in Latin and some in French, and the lesser number in English. Up to that time the English tongue had not yet become thoroughly recognised by Englishmen as the most suitable medium for poetry. The love of poetry was still supposed to be the attribute only of scholars, and a man gifted with a genius for the telling of tales or for the teaching of noble sentiments in verse believed himself more likely to find an appreciative audience by addressing his poems to those who could understand them in Latin or even in French. Chaucer spoke to his countrymen in their own language, and his successful enterprise made a new era in the intellectual development of his country.

James Wycliff was a great preacher, reformer and writer. He was bold and even daring in his efforts to exalt the religious teaching of his order and of the age, and

made himself especially hostile to the Papal Government of Rome. Wycliff was one of the forerunners of that great change which took place in the history of this country when England as a State withdrew from the spiritual domain of the Church of Rome. We mention him especially in association with this period because the earliest of his works were written in Latin, and it was only when he desired to appeal to the English people at large that he addressed them in their own language. He became the first great prose writer in the English tongue. Wycliff died on December 31st, 1384.

**The Fame of a Reign.** King Edward III. was not much devoted to literary culture, although he proved a generous patron of authors in prose and poetry. His reign did much for the development of England's constitutional system, for representative government in a parliamentary assembly, for civic and local rule throughout all parts of the country, and for better administration of justice through courts of law. The historic fame of the reign, however, will be associated more closely with the victories of English armies over the French than with any other events. The struggle with France begun by Edward III. is known as the Hundred Years War, and the influence of that century of battlefield rivalry kept alive a spirit of hostility between England and France which made them enemies down to a period not far distant from our own. In the days of Edward III. the incessant warrings between neighbouring states were to be excused or explained to a great degree by the undetermined limits and conditions of nationalities; by the fact that the sovereigns of England still held some regions in France, that the sovereigns of France still owned some parts of Italy, Austria, and other countries, that the monarch of one state occasionally claimed the right of succession to the throne of another, and that the world in general did not yet recognise the importance of nationality in the domestic government and foreign relations of states.

**Establishment of the Order of the Garter.** We must not allow Edward III. to pass from this history without recording that he established the Order of the Garter, which has been one of the most distinguished and distinguishing marks of the sovereign's favour from that time forward. Edward had, it is said, originally intended to revive the Round Table of King Arthur, and proposed to establish tournaments, to which knights from all foreign countries were to be invited to celebrate the institution. After one of his great victories on French battlefields, generally understood to be that of Crecy, King Edward created a new order, and, according to some historians, called it the Order of the Garter because he made use of his garter as the signal for the opening of the battle. Other accounts say that the new institution, which was founded somewhere about April, 1344—different dates are given also—was originally called the Order of St. George, and only in the reign of Edward VI. was called the Order of the Garter.

# MILLS AND MILLING

Milling Machinery. Cleaning and Conditioning. The Roller Mill.  
Flour, Middlings, and Semolina. Prepared and Predigested Cereals

By CLAYTON BEADLE and HENRY P. STEVENS

**THOUGH** at first primitive man used his teeth as the grinders for his grain, we come across references to grinding implements and mills in very early records. Flat stones consisting of a fixed stone and upper stone or runner are still to be found to-day, but are being rapidly replaced by the modern machinery we are about to describe.

**The Wheat Grain.** As will be seen from the diagram [1], the wheat grain consists of an oval shell composed of several layers surrounding a mass of starch cells, and the object of the miller is to separate the starch cells as completely as possible from the outer shells (bran and other residue, termed "offals").

All milling machinery is devised with the object of producing the largest possible proportion of pure flour, the "broadest" bran, and the cleanest "offals." The reason for this is obvious—flour is supplied for human consumption, and commands the highest price, whereas the bran and offals are of inferior value, and only suitable for cattle food and similar purposes, although brown bread contains a certain proportion of bran. Further, with modern machinery, the separation of flour and offals is best attained by scraping the kernel of the grain out of its covering with as little damage as possible to the former. This yields broad bran—that is, bran in large pieces.

**The Roller System.** In the modern method, where the grain is passed between several pairs of rollers, the separation of the offals takes place during the grinding instead of afterwards. The wheat also undergoes a very thorough preliminary treatment in which it is separated from foreign ingredients and thoroughly

cleaned before milling. The grinding is effected in the first place by fluted steel or "chilled iron" rolls, between which the material passes, so that the individual grains are cut or slit as thoroughly

as possible, without crushing more of the kernel than is necessary. Much of the bran and offals can be removed in this manner before the kernel is finally reduced to flour. Speaking generally, the product is treated to separate the bran from meal, after passage through each pair of rollers. The meal has further to be separated into flour and unrefined "endosperm" from the interior of the grain by first crushing between smooth rolls. After each treatment, the products pass to machines for separation into flour and "semolina," or "middlings." The latter are again reduced by passage between smooth rolls and dressing machines, yielding for instance, in the case of "coarse"

semolina, flour on the one hand, and "sharps," or "thirds," on the other. The principle involved in these operations will be better understood by reference to the diagrammatic table on the next page.

**General Principles.** The ideal aimed at in milling machinery is to strip off the covering of the kernel and remove the bran before reducing the interior of the grain. It will be understood that this latter requires further treatment, as it is made up of numbers of tiny cubes containing the flour enclosed in a fine skin. These must be reduced before separation into flour and middlings, or semolina, can take place.

So perfect are the modern systems of roller milling, as represented by the Robinson system and the practices of other British firms, that there is less than 1 per cent. waste in treating the wheat

3. Cleaned and conditioned wheat  
4. Cockle and broken wheat extracted by indented cylinders  
5. Extracted oats and barley

when once it is cleaned and conditioned. The yields may be given approximately as: flour 70 to 72 per cent; offals (sharps, pollard, and bran), 27 to 29 per cent.; waste, 1 per cent.

**Explanation of Terms.** The finest ground product is the *flour*; the particles of "*dust*," are a trifle coarser; *middlings* coarser still, and *semolina* the coarsest of all. The three latter, of course, are ultimately reduced to the first—viz., flour.

"Sharps" are the finest particles of the shell or outer coating of the grain separated in the final stages of milling. They correspond in size to middlings. *Pollard* is composed of larger pieces, and the *bran* represents pieces of husk but little damaged by passage through the fluted rolls.

**Milling Machinery.** We will now proceed to describe in detail the construction and method of operating the most modern form of plant for milling wheat. After this we will go through a mill and see the course which the wheat, and then the offals, flour, and bran, travel through the different machines on their way from the "silos" or bins, where the raw material is stored, to the "sacking spouts" and patent packers where the finished products are caught off.

**Cleaning.** This entails quite a number of separate operations, the first of which is carried out in a wheat separator and scourer [11], in which the wheat is separated from coarser impurities, such as sticks, stones, and large refuse generally, and scoured to free it from adhering particles of dirt, and break up little balls of earth, always found to a larger or smaller extent in sacked corn.

Fig. 10 illustrates the action of this machine. The uncleaned grain falls into a separating sieve which is kept constantly on the jog. The efficiency of the separator is considerably augmented by the currents of air sucked through the machine by the fan situated above. Air

is drawn through the stream of uncleaned grain as it passes on to the sieve, and through the cleaned grain as it leaves the machine, carrying impurities [7] with it. After leaving the sieve the material is conducted to the interior of a perforated steel cylinder, where it is scoured by

rapidly revolving beaters, which cause the grains to rub against themselves so that the loosened dirt and dust pass through the perforations in the cylinder, and the cleaned grain finds its way out at the other end.

**Washing.** It is also necessary to wash the grain with water to free it from stones [8] and dirt, which could otherwise only be got rid of by very prolonged action in the scourer, where such drastic treatment would probably damage the outer skin. In soft wheats, such as "Chirkas" and "Platas," the immersion in water must not be prolonged, and the moisture should be rapidly drained off.

The washing and subsequent drying, or conditioning, in some cases toughen the bran, so that it is more easily detached in large pieces, and hard wheats require moistening, not only to enable them to mill better, but because the flour produced from them is better in colour.

Robinson's wheat washer, stoner, and rinser is shown in 12. The wheat as it enters at the

right-hand top side of the machine is met by a jet of water and carried round with it by a revolving paddle which effectually immerses it. The wheat and water flow down an inclined plane, at the bottom of which they meet another stream of water moving upwards, adjusted to such a pressure that the stones, being heavier, sink, while

the grain is carried over into another tank, whence it is lifted by the "worm" seen on the top left-hand side of the machine. Streams of water play on the grain as it is being removed by the draining worm. The spent water is carried away through the perforations after thoroughly rinsing the grain.

DIAGRAM OF THE PROGRESS OF WHEAT TO FLOUR  
(The bracketed figures refer to the illustrations)

10. DIAGRAM OF SEPARATOR AND SCOURER

**The Whizzer.** To rapidly remove the adhering water from the grain, the latter is conducted to a "whizzer," which consists of a revolving drum to which lifting plates are fixed. These are short, projecting pieces of metal placed diagonally, so that the wheat fed in at the bottom is lifted up and carried to the top of the cylinder. Meanwhile a strong draught blows through the grain, and, by the centrifugal action, the water is thrown off and driven through a perforated casing surrounding the drum. The wheat is, however, by no means dry, and much of the superfluous moisture has still to be got rid of.

**Drying and Conditioning.** Wheat is not required in a "bone dry" state for milling; a certain percentage of moisture is beneficial and even necessary, and the machine we are about to describe can be adjusted so that the grains retain the right proportion. This is what is meant by conditioning.

Mallinson's machine is shown in section [13]. It consists of two hoppers, A and D, into one of which, A, the grain passes from the whizzer, whence it descends between the wall or casings, BB, being checked in its fall and turned over at intervals by pieces of metal projecting inwards, and leaves the casing at C. Inside the right-hand casing are a number of vertical steam pipes, one of which is seen in the drawing. At the bottom is a steam chest and the air entering at E is heated by passing between steam pipes on its way to the hot-air chamber, F, and is then drawn by a fan through the wheat in the direction shown by the arrows. The grain which leaves at C is elevated and deposited in the hopper D, whence it passes down the left-hand casing MM. The material is cooled before leaving at H by a current of cold air entering by the channel K.

The heat given off by the steam pipes inside the casing below A causes the wheat to sweat, and brings the moisture to the surface, leaving the interior of the grain in an excellent condition for milling, and at the same time toughening the skin so that the bran can

be stripped off in large flakes. Steam pipes are omitted from the casing MM, as experience has shown that gradual cooling is an essential factor in successful conditioning of wheat.

**Brushing.** To remove the remaining dirt and dust, the grain is treated in a wheat brush. The action of this machine will be understood by reference to the diagram [15]. Its construction is similar to that of the scourer [10 and 11]. The wheat is led into a perforated steel cylinder, containing a drum fitted with rapidly revolving brushes which brush the wheat and remove any smut or dirt loosened by the action of the washing and drying machine. The dust falls through the perforations in the cylinder.

**Extracting Cockle.** Wheat always contains a certain proportion of foreign seeds and cockle [4], which are removed by cylinders of special construction [14]. The cockle cylinder consists of a slowly-revolving drum, the inner surface of which is formed by a zinc plate drilled with a great number of small holes or indentations of peculiar shape [16], in some cases as many as 30,000 to the square metre. As the cylinder revolves it gathers into the indentations the cockle and small foreign seeds. When they reach a certain position they fall off again into a conveyor, or trough suspended in the lower half of the cylinder, which carries them to the outlet. The clean grains, now ready for milling, pass out at the end of the cylinder, and are elevated to clean wheat bins.

**The Roller Mill.** The machine in which the actual grinding takes place [17] is built with two pairs of rollers placed diagonally, although many machines have the rolls placed horizontally. The diagonal arrangement, however, has certain advantages and is described here [19]. The rolls make the same number of revolutions per minute, but as one roll, A, is smaller than the other, B, the necessary differential is obtained at the point of contact, and a shearing effect produced in this manner, instead of having rollers of

11. SEPARATOR AND SCOURER  
(T. Robinson & Sons, Ltd., Rochdale)

the same diameter with gearing to different speeds. The rolls are either fluted or smooth. The fluted or "break" rolls are used for splitting the outer covering of the grain, and smooth rolls for the final stages of grinding. Above the rolls is a shaker feed, which is well adapted to material treated with break rolls, but roller feeds can also be used. Underneath the tray, DD, is the eccentric shaft and block E, which causes the former to vibrate, so that the material passes in a regular stream underneath the "hinged spreading boards," FF, on to the "splash" boards, GG, which guide it between the rolls.

**Sifting and Dressing.** Grain which has passed through the first pair of break rolls [8] is treated in a sifter and scalper [18] which separates the material with the aid of rotary sieves suspended almost vertically. This separation is of a preliminary nature; the real dressing or sifting of the flour is effected in a centrifugal dressing machine [20] which consists of a skeleton cylinder, A, covered with silk gauze of fine mesh fixed horizontally and rotating slowly [21]. It contains a number of beaters, B, which revolve rapidly. The material to be treated is fed into the cylinder, and by the action of the beaters is forced against the gauze, whereby the flour is "dressed" or sifted through. Underneath the cylinder is a trough with a conveyor, C, which removes the flour while the unsifted material passes over the end or "tail" of the cylinder for further treatment. These machines are often provided with two conveyors lying side by side in separate troughs (C and D). There are a number of hinged covers which shut in either conveyor so that the flour finds its way into one only, as C in 21. If now one half of A be covered with finer gauze than the other, it will let through finer flour, which will collect in the trough open beneath it, so that with the necessary adjustment finer flour will be delivered by one conveyor and a coarser grade by the other. By suitable arrangement of "cut offs" the flour may be graded into different qualities in one machine. We should mention that over the gauze-covered cylinder A are brushes, to keep the perforations in the silk from getting clogged.

**Purification of Middlings and Semolina.** Middlings consist of wheat particles reduced to a certain extent by passage through break rolls, while semolina is practically the same thing, except that the particles are coarser.

The machine known as a "purifier" effects a sort of double separation on either of these materials as its action is twofold. In the first place, it consists of a long flat sieve kept vibrating by the action of an eccentric [23]. The sieve is divided into four parts, each of which is covered with gauze of different mesh. The tailings, consisting of particles too large to pass through the sieve, are taken to the rolls for further re-

duction. A brush travels up and down underneath the sieve [22] to keep it free and open. As the middlings pass along the sieve a strong current of air is drawn up through them by

12. WASHER AND STONER  
(T. Robinson & Sons, Ltd., Rochdale)

means of a fan, so that all light impurities (offal) are lifted out and carried up, only the heavier portions being sieved. Fixed immediately above the sieve are a number of V-shaped intercepting channels, on either side of which are deposit platforms; the air currents passing up from the sieve and carrying the light impurities pass between the channels into the expanding chamber above, where most of the matter is released and falls. This is shown diagrammatically in 24—a vertical section of the expanding chamber.

The peculiar construction of the intercepting chamber causes the greater part of the material to deposit on the platforms on either side of it. Should any material be carried further, it is deposited in a second expanding chamber above the first, and the air currents pass to the fan practically free from dust. The vibrating action of the sieve causes the light impurities (offal) to move down towards an outlet, as sieve, platforms, and intercepting channels are fixed at a slight inclination. The deposit on the upper platform is swept down by an automatic "brush cleaner," and by a suitable arrangement of worms and channels the combined deposits of offal are removed from the machine. The machine is also provided with cut-off

13. SECTION OF DRYER AND CONDITIONER

14. COCKLE CYLINDER (T. Robinson & Sons, Ltd.)

boards and a double worm at the bottom, so that those portions which pass through the different mesh sieves or any combination of them may be kept separate as desired.

**A Working Mill.** We shall now indicate how these machines contribute individually and collectively to the separation of flour from wheat.

Fig. 28 shows a model of a small mill of about two sacks per hour capacity, and 26 is a diagrammatic section of this mill, in which the flow of the material from one machine to the next through the mill is indicated by arrows.

On the left hand is the wheat cleaning and conditioning department, and on the right hand the actual flour milling. In the former the grain is elevated to the top floor, and passes straight through the various machines in the order in which we have described them.

**The Milling Department.**

In the next department the sieve and scalper [18], as well as the grading and dressing machines [20], are on the top floor. The second floor is taken up by the purifiers, and the roller mills occupy the first floor, the first three pairs being fluted. The ground floor is reserved for the shafting and pulleys that transmit the motive power to the various machines on the floors above.

Let us start with the cleaned and conditioned wheat [3] as it leaves the clean wheat bin, whence it is spouted to the first pair of fluted rolls just below. The flutings of these rolls are coarse, and the rolls are comparatively wide apart, so that they crack the grain, partially setting free the kernel. This material [8] from the first "break" is elevated to the rotary sifter, which separates it into three parts, according to the size of the particles—1, the coarse wheat particles; 2, coarse semolina (coarse particles of the endosperm); 3, fine middlings and flour (still finer particles).

The coarse wheat particles are spouted to the second pair of break rolls on the first floor. These rolls are set closer, and the flutings are not so coarse as in the first

pair; their action is to release more semolina, and the resulting products [9] are elevated to the dressing machine on the top floor for further separation. The coarsest particles (overtails) from this machine consist mostly of large pieces of bran which retain but little floury matter, and are taken to the third pair of break rolls, which are more finely fluted than either the first or second pair. By their action the remaining particles of flour are scraped from the pieces of bran, and separated by elevating to the centrifugal dressing machine [20] on the top floor.

We have now followed the coarse wheat particles through the three pairs of rolls, leaving the grain in various stages of reduction (semolina and middlings), from which the greater part of the bran has been separated. In larger mills we find more than three pairs of break rolls, but the principle involved remains the same.

**Treatment of Semolina.**

Having traced the course of the first product—the coarse wheat particles, let us now take up the second—the coarse semolina. It will be remembered that we left this at the rotary sifter, where

it was separated from products one and three; it is spouted to No. 1 purifier on the second floor. The purified semolina which has passed through the sieve of this machine goes to the first pair of smooth rolls underneath for further reduction. The tailings of the sieve go back to the fluted rolls, and the offal, which does not require any further

15. WHEAT BRUSH

16. SECTION OF INDENTED PLATE

17. DIAGONAL ROLLER MILL (T. Robinson & Sons, Ltd.)

treatment, is carried away in a third direction. It is not possible to demonstrate the course of all these products in the plan [26], so that we have indicated by arrows the path of the main product, the purified semolina, only. After passing the smooth rolls, it is elevated to a centrifugal dressing machine on the top floor, where the flour is "dressed" out, and the tailings pass to the separating sieve on the second floor. Here the germ is eliminated, and the unreduced portions pass to another pair of smooth rollers, to be again elevated to the top floor, and delivered into a dressing machine to separate the flour. In each case where flour is extracted by the dressing machines it passes away by the conveyer underneath to the sacking apparatus. The overtails are again reduced by roller mills, and then dressed till all the flour is extracted, leaving nothing but finished offal.

**Treatment of Middlings.** The third product, the fine middlings and flour, are treated in a centrifugal dressing machine to separate the flour from the middlings, the latter then passing to purifier No. 2 on the second floor. The further treatment of the products resembles the process we have already described in speaking of No. 1 purifier. The overtails from both pass to fluted rolls, to be worked up with coarse wheat particles, while that portion which passes through the sieves goes to smooth rolls for further reduction. In both cases, after repeated grindings and dressings the whole of the flour is removed, and nothing remains but finished offal—sharps, or thirds.

In the grinding and repeated treatment to which such finely-divided material is subjected, much dust and fine particles would escape into the atmosphere if special precautions were not taken. The rollers and other machinery are connected with air trunks

19. DIAGRAM OF DIAGONAL ROLLER MILL

18. ROTARY SIFTER AND SCALPER  
(T. Robinson & Sons, Ltd.)

—long channels or elongated boxes—through which air is drawn by a fan. This exhaust carries the dust to a dust collector, a large cylindrical box within which the air currents course, striking the walls and depositing the dust on the sides and bottom, where it collects, and can be removed. The air current may also have some effect in levitating the flour and help to keep the rolls cool.

We have outlined the arrangements in a small mill of two sacks per hour, but in larger mills these would be considerably amplified, and, generally speaking, more complicated. With more machines—say, for instance, five sets of break rolls instead of three—the reduction and separation would be more gradual, and consequently more complete. The cut-offs may also be made greater use of so as to separate the products from each machine (purifier or dresser) into two or more

20. CENTRIFUGAL DRESSING MACHINE (T. Robinson & Sons, Ltd.)

portions, each of which may be kept separate for further treatment. Take, for instance, the cylindrical sieve of a dresser [27]. All flour that passes through the gauze of fine mesh, Nos. 11 and 12, is taken away to the flour sacks as finished product, but the cut-off material which passes through the coarser No. 5 mesh gauze would in a large mill be kept apart and treated separately from the overtails. It may also be necessary to modify the treatment from time to time according to the class of material dealt with, so that it is not possible to give a standard to which all milling processes will conform. The examples we have chosen are, however, as nearly as possible typical of an up-to-date installation.

**Cereals Other than Wheat.**

In conclusion, we would call attention to the ever-increasing special treatment of various grains in the preparation of patent, breakfast, and other foods. Oats in the form of porridge made by boiling the coarsely ground cereal form an important food product in this country, but are now being replaced by various brands of prepared oats obtained by steaming the grains, crushing them between rollers, and then drying them. Such treatment in the preparation of so-called "rolled oats" ruptures the cell walls and partially cooks the

grain, so that it requires less cooking for the table and is more palatable than untreated oatmeal. The majority of the widely-advertised breakfast foods are produced in much the same manner as wheat flour as regards the first stages. As in the milling of wheat, the first treatment consists in cleansing the grains, which, to be thoroughly cleansed, should be put through the scourer, separator, washer, stoner, and brusher already described. The clean grain then passes through coarsely-fluted rolls to remove the outer coat, but there is no need to make a complete separation of the interior portions of the grain from the bran as in the production of white flour. Sometimes the grains are first soaked in a weak alkaline solution to aid the removal of the outer skin, but in every case the grains are rolled after removal of the coarse bran.

In this state the products require a good deal of cooking before they are ready to be eaten. "With other brands the treatment is carried much further. Some of them are partially cooked, and, while still requiring some cooking, the time of cooking is much less than for material not so treated. Some brands are said to be wholly cooked, and ready to be eaten as they are taken from the package. Some brands are claimed to be not only cooked but also predigested. Further than this it is hardly possible to go!" (Milner.) The products may be partially cooked by steam heating

24. SECTION SHOWING CHANNELS AND EXPANSION CHAMBER OF PURIFIER

25. CROSS SECTION OF PURIFIER

23. PLAN OF PURIFIER SIEVE

as in the case of "rolled oats," and in some cases by carrying the cooking further, and then rolling as in the case of the thin "flake cereals."

In other cases, again, the grains are roasted, or first moistened and then roasted, so that on crushing them granular products are produced resembling dried crumbs.

The shredded preparations are obtained by working the softened grains in suitable machinery.

### Predigested Foods.

To realise the aim and object of the treatment to which these so-called predigested or malted foods are subjected we must remember that the starch of which they are mainly composed [see STARCH] is itself an insoluble substance, and is not available for nutrition until it has been acted upon by certain ferments present in the alimentary canal. Thus the pancreas secretes a fluid which has the power of acting on starch with the formation of soluble substances (sugars), which then by further action are absorbed into the system. This property of acting on (hydrolysing) starch is possessed by other substances besides those found in the digestive tract. In germinating barley there is, for instance, a peculiar ferment (enzyme) termed diastase, which is so far similar in its behaviour to the action of the pancreatic juice that it converts the starch into a sugar (maltose). This process,

however, does not use up the diastase, a small quantity of which is capable of transforming large quantities of starch into maltose. If

crushed cereals containing starch be macerated with a small quantity of ground malt (barley arrested in the early stages of germination), and the mass be kept warmed,

the ferment will convert a part of the starch into sugar (maltose). The dried mass will then contain part of its constituents in a shape similar to that obtaining in the alimentary canal in the first stages of digestion, and may therefore be regarded as in a partially digested state.

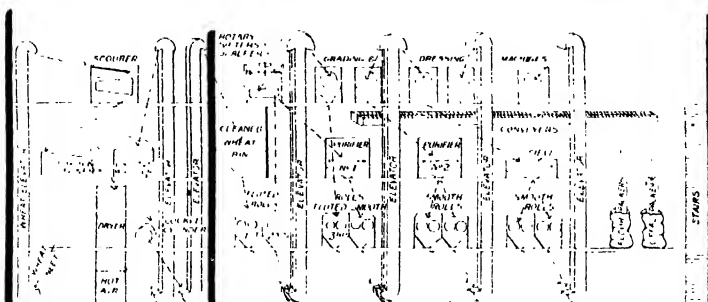

In actual manufacture the action of the diastase is not allowed to go on too long as small quantities of by-products would be

obtained, giving rise to unpleasant flavours. For this reason many malted or predigested

foods contain only a small proportion of their starch in the form of sugar. However that may be, actual feeding trials have shown that these so-called predigested foods have little or no advantage over ordinary wheaten bread in nutritive value in spite of what is frequently claimed for them. It will be found difficult to improve upon the ordinary

wheaten bread made from grain which has been carefully cleaned and properly milled.

28. FLOUR MILL ON THE ROBINSON SYSTEM

By Professor SILVANUS P. THOMPSON

**A** DRAWBACK with electricity when used for lighting purposes is that it cannot be stored to anything like the same extent as gas. If the gas generators break down, there is a supply of gas in the gasometers to go on with for some time. With electricity we have, however, a method of storing electric energy, to be correct, and not electricity itself, but the apparatus is so costly and cumbersome that it is not practical to install it to such an extent as to cope with the total demand of a station for any length of time. It is these facts which add force to the remarks made on page 2816 on the subject of the economic generation and the charging for electric energy.

**The Secondary Cell.** The apparatus used for the storing of electrical energy consists essentially of a voltaic cell [page 462], the plates of which consist of lead or compounds of lead. This makes them heavy. Their electromotive force is about 2 volts, so that for the ordinary light and power circuits of to-day, running at 200 volts, over 100 of these cells are required. Also, they can be used only with continuous currents.

In country-house installations where a little extra expense is not a consideration, and where the load is quite small, storage batteries are put in which will deal with the full demand; but in large stations a battery of such a capacity only can be installed as will *help* the engines and generators during the period of the highest load.

The fundamental principles on which the electric accumulator is based have already been given on page 463. We saw there that when a cell is made of zinc and copper dipping in dilute acid, bubbles are formed on the plates, due to the chemical action of the current, and these bubbles polarise the cell or set up an electromotive force which, opposing that of the cell itself for the time being, renders the cell useless. In 1860, Planté devised a cell of two sheets of lead, which in themselves, of course, gave no electromotive force, but when *charged* from an outside source, an electromotive force counter to the source of supply is set up, due to the negative plate becoming covered with a coating of the brown peroxide of lead, the positive plate at the same time assuming a spongy metallic state, so giving a large amount of surface of high chemical activity. In Planté's original type, he took the two lead strips and rolled them up

in a spiral, so that the cell appeared as shown in 210. The process of forming Planté's accumulator was long, as it had to be charged and discharged carefully many times before it was completely made and ready for use.

**Faure's Pasted Plates.** In 1881, Faure modified the Planté accumulator by giving the two lead plates a preliminary coating of *red lead*. When a current is passed through the cell, the red lead is peroxidised at the anode, and reduced in a succession of stages to the spongy lead state at the kathode, and thus a greater thickness of active material is provided which takes a much less time to form, but is mechanically weaker.

## Present Day Construction.

Most manufacturers have now followed Faure's method, but they provide a better mechanical support for the active material. A modern type of cell, as fitted in a glass box, is shown in 211. The first process in the construction is the casting of a leaden grid, which is to hold the paste. The patterns of these grids are different with almost every firm, the object in the various designs being to obtain as rigid a support for the mass of paste as is consistent with a minimum amount of metal, for the grid is entirely inactive from the electrical point of view. A common construction of grid is shown in 212. In the melting of the metal for casting, a small percentage of antimony (a constituent also of type metal) is added to impart rigidity and hardness to the soft lead. No other metal is found to withstand the action of the acid, aluminium having been tried on account of its lightness, and failed.

210. PLANTÉ'S ACCUMULATOR

The paste is made by mixing up the red lead (or *litharge*) with dilute acid in a mixing mill, and it is then worked into the grids as mortar is spread along a line of bricks. The lugs of the plate thus pasted are then cast together in batches, according to the capacity of the cell, and the plates are then erected in temporary glass tanks, and the current for forming them is passed through them continuously. In the course of hours, the one plate becomes gradually reduced to spongy lead, and the other is further oxidised to form the required brown peroxide.

**Capacity of Accumulators.** What is known as the *capacity* of the cell is measured in ampere-hours. To understand how this

quantity is arrived at, we must know something about the voltage variations which take place. When an accumulator is fully charged, its electromotive force reaches 2.5, and on continuing the charge, gas is freely evolved in fine streams, so that the liquid appears quite milky. On discharging, the voltage rapidly drops to 2.15, and after this it drops quite slowly during the main period of the discharge to about 1.85, at which point it must be considered to be fully exhausted, for should current be taken from it any longer, the electromotive force decreases rapidly to zero, when the cell is practically useless for any further work. The voltage during discharge is shown by the first line in 213. On charging, as might have been supposed, we must put more energy into the cell than we get out of it, and so, assuming for the purpose of comparison that we are charging with the same current, the voltage which must be applied will be slightly greater than for the corresponding epoch of discharge, and the variations are shown by the and line in the figure.

**Capacity of a Cell.** Now there is a limit to the current which we can take from an accumulator. The greatest current it would be possible to take would be by short-circuiting the terminals, but with this the electro-chemical action in the paste is so violent that the paste disintegrates, the plates themselves buckle, and the voltage is speedily reduced to zero, from which it is practically useless to try to raise it. The safe carrying capacity of a cell depends, as will be apparent, chiefly upon the exposed surface of the plates, and to a less extent upon the thickness of the plate, and it has been found that we may take about  $7\frac{1}{2}$  amperes for every square foot of positive or negative plate. The time taken for the voltage to fall to 1.85 on discharge or to rise to 2.5 on charge depends on several things, including chiefly the total amount of active material in the cell, and the product of this time and the safe rate of discharge in amperes gives the capacity of the cell in ampere-hours.

For the sake of comparison, cells are often quoted as so many ampere-hours per lb. of cell. No definite figures can be given for this rating

as it varies for each type of cell according to the use to which the cell is to be put. For instance, traction cells are made comparatively light, but have a shorter life, and some cells are made up in lead-lined wooden boxes, while others are enclosed in lead entirely.

### Efficiency of Accumulators

We do not, of course, get the same amount of energy out of an accumulator as we put into it. When the cell is being worked normally, the efficiency—i.e., the ratio of these two quantities—is between 90 and 95 per cent. When, however, it is discharged at a greater rate, the time taken for the voltage to drop to its minimum value is less than proportionately shorter and a lower efficiency results. These facts are well illustrated by the table on the following page, which deals with an experiment on a well-known make of accumulator. The cell itself was rated at 100 ampere-hours on a 10-hour discharge—that is, it would give 10 amperes for

10 hours, during which time its voltage would have gradually dropped to 1.85.

**Deterioration of Accumulators.** In course of time, as the accumulator ages, the paste gradually drops out of the plates. This is, of course, expedited by bad usage; but with ordinary usage it will occur. The

paste falls to the bottom of the cell, and the suspension of the plates should be such that adjoining positive and negative plates are not short-circuited by a layer of this powder. If the paste come out in lumps, it is likely to get clogged between the plates before reaching the bottom. Especially is this so in traction cells, where everything is made as compact as possible; and to guard against this difficulty the only course is to inspect the cells very frequently. In order to minimise the wasting of paste, many makers have sought to embody the plates in a substance of semi-solid consistency, such as a mixture of water-glass (sodium silicate), with the

exciting liquid sulphuric acid, or by using a packing of felt or some such porous substance; but these devices have not been found altogether successful, as the paste will disintegrate, and it is best to allow it a free

211. MODERN TYPE OF FAURE'S ACCUMULATOR

212. ACCUMULATOR GRID READY FOR PASTING

passage to the bottom of the cell. A brown or positive plate is found to have only half the life of the grey or the pure lead plate of similar type of construction. This will be easily understood when it is remembered that the negative plate is of pure metal, while the other is still only a powder, which has been rendered solid for the time being by being made up in the form of paste. Further, in connection with this matter, it is the general rule to have an odd number of plates in a cell, the two outside plates of the compound sandwich being negatives.

**Supporting the Plates.** It is a difficult matter to support in a thorough mechanical

213. VOLTAGE VARIATIONS DURING CHARGE AND DISCHARGE

way a number of heavy lead plates with a minimum allowance for clearance. They must not be allowed to rest on the bottom of their box, because then the fallen paste easily short-circuits the plates at the bottom, nor for the same reason may they be supported upon wooden blocks. The usual method is to cast the grids with side lugs, as shown in 212, which rest on the top of the boxes as in this case, or, if arranged further down the grid so as to be below the surface of the liquid, on wooden or glass supports, which are fitted against the two sides of the box, and rest on the bottom. The plates themselves are kept apart by insulator rods of glass or ebonite, which are placed between them during erection.

**Care of Accumulators.** There are perhaps no more delicate pieces of apparatus coming under the care of the electrical engineer than accumulators. To keep them in good condition they should be charged and discharged as regularly as possible, and, if possible, should not be partially charged and then partially discharged, as by treating them in this irregular manner they deteriorate much more quickly. Another important matter is to keep the acid at the correct specific gravity [see PHYSICS]. This varies during the period of charge and discharge, as the chemical actions which go on involve the splitting up and remaking of molecules of water. The correct specific gravity at the full discharge is about 1.175, and at full charge 1.21. Cells should be tested with suitable hydrometers at least once a week to see if these

conditions hold, and in cases of high density, which sometimes occur on account of surface evaporation and spraying, should be at once remedied by the addition of distilled water. It will sometimes be found in a number of cells that one or two are not keeping up their voltage. These should be disconnected from the set and given a special charge for about four or five times longer than usual, when it will often be found that they have come up again to the normal state. Most manufacturers issue detailed instructions with their cells and these should be carefully followed. With large batteries, also, it is usual for the makers to contract to keep them in order for a period of years.

**Housing of Accumulators.** The accumulator house should be shut off from all other parts of the building, and, if possible, should be a distinct erection. The use of metal in its construction should be avoided if possible, the roof principals being made of wooden beam, which can be heavily varnished or coated with some acid-resisting paint. All electric conductors should be treated in the same manner. To stop the spray during charging from spreading throughout the rooms, some makers place cork granules or hollow glass balls on the surface of the liquid; but a more general, although not so effective a remedy, is to rest a glass plate across the supporting lugs at the top of the plates.

**Use of Storage Batteries.** Several uses of storage batteries have already been mentioned, such as a standby in case of accident or a help in case of excessive demand. The small accumulator is also a handy source for portable use, and many sets are sold for cable testing and field telegraph work in which they have supplemented the older primary batteries. Perhaps the most valuable use of the battery is on traction systems where the load is continually fluctuating in value. These fluctuations do not conduce to the good working of the generators, and so a battery is installed parallel with them, and this takes the large momentary demands, receiving back its energy in turn from the generator in times of a slack demand. This

HISTORY OF ART  
continued from  
page 2035

By P. G. KONODY

**E**ARLY Christian art is the connecting link between antique pagan and mediæval or Christian art proper. It fills the gap between the Classic and the Gothic period. It starts in the sheltering obscurity of the catacombs, whence it issues victoriously, spreading far and wide and annexing not only the material of the deserted pagan temples and halls of justice, but in many cases the very forms of construction and artistic expression. Thus in the West, in Rome, the Pantheon, a heathen temple, was adapted for the requirements of Christian service, whilst the form of the Roman basilica was, for a time, chosen as the definite form of early Christian church buildings. Columns and other remains of Roman buildings were freely used for these new edifices, cut down if too long, or added to if too short—put together as they happened to come to hand, without regard to the style of the capitals, shafts and bases.

**The Basilica.** The basilica lent itself most readily to religious service, owing to its division into the apse at the back, which was reserved for the bishop and the officiating priests, and the nave and aisles for the community. The altar was erected in front of the apse, under a canopy, or baldachino, supported by

marble columns. A kind of triumphal arch separates it from the nave. The lofty nave is divided from the lower aisles by a colonnade on either side, which supports the clerestory wall, through the openings of which daylight floods into the interior. The entrance gates are opposite the apse, and access is gained through an open colonnaded court, or atrium. At times a transept was introduced, which converted the plan into a Latin cross, of which the nave was the long arm. The niche-shaped apse, the walls of the triumphal arch, and sometimes the clerestory walls were richly decorated with figures of saints, either painted or in mosaic with plentiful use of gold. The most magnificent building of this type is the basilica church of St. Paul, Rome, which was destroyed by fire in 1825, but has since been rebuilt on the original plan [37].

Another form of early Christian building which was derived from Roman prototypes was the circular or polygonal baptistery, which up to about the sixth century was a separate building, and which was constructed on the plan of the Roman tombs, with the one difference that the columns which divided the interior, as it were, into a circular nave and surrounding aisle had to serve an architectural function as

37. INTERIOR OF THE BASILICA OF ST. PAUL, ROME

Anderson

supports to the walls carrying the dome. Characteristic examples are the church of S. Stefano Rotondo, and the Baptistery of the Lateran, in Rome [39].

**The Byzantine Period.** With the decline of the Western Roman Empire, Byzantium, now known as Constantinople, became the centre of the civilised world. The churches erected in the time of Constantine and of his immediate successors still followed the basilica plan; but in the fifth century, under Justinian, the art, and more particularly the architecture, of the Eastern Empire received a definite stamp and fully developed the tendencies which constitute the Byzantine style. Byzantine life is reflected in the painting and sculpture of the period, which soon took settled, dogmatic forms incapable of further development. In architecture, however, the general use of the dome (which was taken from the East rather than from Roman examples), and all the changes it carried in its train, introduced new life and new possibilities into this art.

A lofty central dome is generally connected with quite a system of smaller cupolas and half cupolas, and necessitates a circular plan instead of the rectangular nave. In order to join the cupola to the square walls, the curved triangular pendentive or spandrel has to be introduced, resting on mighty shafts. Through these devices large wall spaces were gained, which gave special opportunities for sumptuous mosaic decoration. The kernel of the Byzantine churches consisted of bricks and mortar, cased on the outside with marble, and decorated in the interior with paintings and mosaics. In fact, whereas in Rome the dome was used in conjunction with the Greek trabeated system, and the effect depended on architectural articulation, in Byzantium the tendency was in the direction of flat

surface decoration; and even the capitals, cornices, and friezes gradually lost their clearly marked classic play of light and shade.

### **Famous Examples of Byzantine Art.**

The church of St. Sophia, in Constantinople, now a Turkish mosque with all its former glittering splendour hidden under a coat of whitewash, is the most glorious example of the full flower of the Byzantine style [42]. The colossal building, the central dome of which has a diameter of 107 ft. and a height of 180 ft., was built by Justinian in five years (532-537), which constitutes probably a record in rapid building. Equally famous and characteristic is the church of St. Mark, in Venice [38], built about 1100 on the model of the church of the Holy Apostles, in Constantinople.

From Byzantium the new style spread to Italy and the rest of Europe, taking root first in Ravenna, where the church of San Vitale combines many Byzantine elements, such as the gallery resting on the inner octagonal colonnade, with a plan based on that of a Roman temple. In Ravenna, too, we find for the first time an independent campanile, or bell tower, which is not joined structurally with the church, but rises from the ground in cylindrical shape, crowned by an almost flat roof. In Italy these independent campanili were generally adopted in Romanesque architecture, whilst in Northern Europe the bell tower formed an integral part of the church building. The ill-fated Campanile in the Square of St. Mark's, Venice, which collapsed a few years ago and is now being rebuilt, was the most famous erection of this kind. In England the Byzantine style of architecture has never taken root, but the late Mr. Bentley's new Cathedral

*Antero*

39. BAPTISTERY OF THE LATERAN, ROME

at Westminster presents a notable instance of a successful modern adaptation of Byzantine architecture.

**Painting and Sculpture.** In sculpture and painting, as in architecture, early Christian art in Rome was dependent on pagan prototypes. The subject was changed, but the manner remained the same, and the paintings in the catacombs bear a strong resemblance to the wall paintings of Pompeii. The fear of falling into the errors of pagan idolatry must have acted as a strong check to artistic activity, especially in sculpture, and, indeed, free-standing statues of the period are exceedingly scarce. In painting the danger was less obvious; it is less corporeal, and better suited to the expression of spirituality. Nevertheless, the earliest paintings show few traces of that spiritual ardour which later led Christian art to its most glorious achievements. The repugnance of the early Christians to representing divine ideas in human form led to the introduction of symbols, such as the fish, the alpha and omega, the cross, the palm branch, the vine, and the lamb. Amidst this new world of imagery are still found pagan ideas, such as Orpheus taming the beasts and personifications of day and night, rivers and mountains.

It is quite obvious that the original significance of such subjects had been entirely lost sight of, and that a new application had been given to mythological figures. In painting, as in the relief sculpture on sarcophagi, Roman art was thus perpetuated in a debased form. The artist no longer delighted in the beauty of the idealised human form, and gradually the sense of grace

41. MOSAIC FROM SAN VITALE, RAVENNA

and pleasing proportions was lost, whilst a striving for the expression of spiritual grandeur took its place, until Byzantinism for a time veiled the offshoots of the Roman tradition, which, however, kept smouldering under the sumptuous formalism introduced from the Eastern Empire.

Gorgeous splendour was the keynote of the art that had developed in Byzantium, and found expression not only in the rich decoration of the churches, but in the very costumes, resplendent in gold and embroidery and precious stones, which had replaced the festive white garments of antiquity. A stiff, ceremonial formalism pervades everything—life as well as art. The striving for dignity, repose, and stateliness soon prescribed certain formulas for the representation of the human figure, and certain attitudes which reflect the strictly imposed ceremonial of the Byzantine Court. The figures are unduly elongated, the faces forced into a narrow oval, with large eyes, long, narrow nose, and small chin. The expression is as serious and dignified as the general attitude, and shows no trace of emotional life. Only the miniatures of the period retain faint echoes of the antique and show traces of individuality. The subjects are the same as in early Christian art: Christ in glory, surrounded by angels, the Virgin enthroned in solemn dignity, figures of saints conventionally robed in garments that never suggest the shapes hidden underneath them, and representations of the emperor or empress in state. The mosaics in the choir of San Vitale, in Ravenna [41], are the finest examples extant.

**Arts and Crafts of the Eighth Century.** In the eighth century the iconoclasts in blind fury destroyed most of the works of art of the Eastern Empire; and numerous painters, sculptors, ivory carvers, goldsmiths, and enamellers were driven from the country and took up their abode in Western and Central Europe. In miniature painting, for instance, Byzantine ideas soon ruled everywhere but in Ireland, where an independent ornamental style had taken root.

It is scarcely too much to say that from the eighth to the tenth century the crafts of Europe—

40. COURT OF LIONS, ALHAMBRA

42. INTERIOR OF ST. SOPHIA, CONSTANTINOPLE

Bouffé

always excepting the extreme north, where Celtic ornament had become an ineradicable artistic tradition—were entirely in the hands of Byzantine workers and their followers. Their skill in ivory carving, in metal work generally, and particularly in enamelling and filigree work, in weaving and embroidering, was inimitable.

**Moorish Art.** Byzantine influences, together with those of India, Egypt, and countries conquered by Mahomet helped to shape Moorish or Saracenic art. This art is entirely confined to architecture and ornament—which is generally applied to architecture—since painting and sculpture, or the creation of images, were strictly forbidden by the law of Mahomet. Even in architecture, the Mohammedans did not arrive at a settled style, and their buildings show a curious mingling of sober bareness on the exterior and exuberant ornamental fancy in the decoration of the interior. The mosques did not follow a fixed plan, prescribed by the use to which they were put, like the Christian churches, but are arranged in a haphazard fashion, the only common members being a

spacious court with a fountain for ablutions, a hall for prayer, the “Holy of Holies” for the keeping of the Koran, and slender minarets for the muezzin’s call to prayer. Columns and arches are abundantly used for the extensive halls and arcades, and the inner walls are covered with a wealth of arabesques and ornamental motifs in coloured tiles and carved stone.

**Extensive Use of Domes.** Domes are extensively used, and the arch received a variety of new forms in the hands of the Arabs, who introduced the pointed arch, composed of two segments of a circle meeting in the centre of the arch; the horseshoe arch, formed of a

segment of a circle which considerably overlaps the semicircle, and the oggee arch, which rises from each side like a semicircle and then turns upwards until the two lines meet in a point [43].

Examples of Saracenic art abound in Turkey, in India, in Western Asia and North Africa, and in Spain. The Alhambra, in Granada [40], and the Taj-Mahal, at Agra, are among the most famous buildings of this type.

The Outfit Necessary for Plain Needlework. Materials Required.  
Their Widths and Price. Woollen Materials. Trimmings

Group 9

DRESS

22

Continued from  
page 3015

By AZÉLINE LEWIS

**I**N the making of underwear a knowledge of the "art of sewing," or plain needlework, is the first requisite, for though the machine has superseded hand work of late years to a great extent, it cannot and will not do so on the finer and best kind of lingerie, in which hand work still reigns supreme.

**Requisites.** The requisites for plain needlework must first be considered.

**NEEDLES.** A good supply of the best needles is essential; it is of no use to buy inferior makes, as these bend and are not to be depended on for good work. Various sizes are required, as stitches vary a good deal. Those known as "sharps" are most in use for plain sewing. Nos. 6, 7, and 8 being very useful sizes; but the finer ones will be needed for very fine work, with a supply of "betweens," which are shorter than sharps, and are required for fine whipping, insertions, etc.

As simple embroidery is also required in making good underwear, needles must be provided for this, and care should be taken that the eye will take the thread loosely, for unless this is relatively larger than the body of the needle the silk or thread will drag, and either pucker or tear the material and roughen the thread.

Machine needles are of a class by themselves, and each machine has its own special kind; but, of course, these must correspond with the work, and a coarse needle must not be employed for fine materials.

**Scissors.** Of these two pairs at least are required—one fairly large, for cutting out, and the other short, sharp, and not too finely pointed, for paring away edges of insertion, etc. If very sharply pointed they are liable to make holes or cut the lace which is being inserted, and cause almost irreparable damage. A medium pair for ordinary work may be well added to the list. A *stiletto* is also useful for making eyelet-holes and the first incision for a buttonhole, unless buttonhole scissors are added to the outfit.

**COTTONS.** A fair supply of cottons of the unglazed variety will also be required. Here, again, a good make is absolutely necessary for good work, as the inferior makes twist and break, and the effect is spoiled. The numbers vary somewhat with the makers, but Nos. 40, 50, and 60 may be considered the most useful. For very fine work the higher numbers, 70, 80, 90, and 100 may be needed. For the machine, also, see that the make is good, and use a finer thread for the under than the upper one.

Harris's fine lace threads will also be found admirable for working insertions, etc. For the embroidery portions, Brooks's and the D.M.C. cottons may be recommended; but there are

several other makes which are excellent for the purpose. Linen and flourishing threads will be found useful for linen and also in some cases for flannel work, whilst for marking purposes D.M.C. cotton should be employed, unless the woven letters or ink be preferred.

For flannel work a special make of silk is sold for embroidery, festooning, etc.

**THIMBLE.** A good, well-fitting thimble is also a necessity. If the indentations are at all rough they will catch and tear the thread or silk.

**EMERY CUSHION.** An emery cushion is also a very necessary part of the outfit for those whose hands are inclined to be warm, so that the needle may be passed through this and kept smooth.

**PINS, TAPES, ETC.** Amongst the other requisites for plain needlework we must mention a bodkin for running in tapes and ribbons; some good mixed pins (very sharp-pointed ones); tape of various widths, the smooth India or China make sold wound in oblong forms being the best; linen and pearl buttons of assorted sizes, the former should be all linen, not with holes, as these, when washed, are apt to discolour the material; fine piping cord; a lead pencil to define width of tucks and hems; a small, sharp penknife for unpicking, though this should not be used unless absolutely necessary; a little wax for strengthening cotton if required in gathers, etc., and for the machine if the material contains much dressing; and a good yard measure.

**Materials Employed.** The materials generally employed in the making of underwear are given below, with their respective widths, as they vary a good deal, and thus considerably affect the quantities required for the different garments.

**LONGCLOTH AND CALICO.** These are employed for ordinary underwear, either plain or twilled. They are usually a yard wide, although the better qualities run to 41 in. and 45 in. in width.

**MADAPOLAM.** This is a very fine, soft make of longcloth, which is generally employed for fine underwear, as it is almost entirely free from dress. It is about 42 in. wide, and may be had in a good quality from 10½d. per yard.

**UNBLEACHED CALICO.** Unbleached calico is much used by the working and poorer classes on account of its cheapness, as it can be bought from 2d. per yard. If properly washed it soon loses its yellowish tint, and is excellent for charity purposes.

**ENGLISH NAINSOOK AND CAMBRIC.** These are fine and thin in texture, and are used for fine underwear—chemises, camisoles, frills for ornamental purposes, etc., and vary from 30 in. to

45 in. in width, the prices being about the same as longcloth and madapolam.

**FRENCH NAINSOOK.** Somewhat finer in texture than the English make, and is about 42 in. wide.

**FRENCH CAMBRIC** varies from 26 in. to 34 in. in width.

**IRISH CAMBRIC.** 26 in. wide.

**FRENCH MULL.** This is also employed in the best underwear, and is 47 in. wide.

**LINEN.** Though not so much used in these days, linen is still extensively employed in the finest makes for the highest class underwear.

**IRISH LINEN.** About 36 in. wide.

**FRENCH LINEN.** 32 in. wide.

**FRENCH LINEN LAWN.** This is a particularly fine and beautiful make of linen, varying from 36 in. to 40 in. in width, but is somewhat expensive, the best being about 4s. 6d. per yard.

**IRISH LINEN LAWN.** Runs about 36 in. in width, and, like the last eight makes, is only suited to those who need not consider the price.

**WASHING SILK.** In addition to the above-named materials, silk is now largely employed for fine underwear. It should be of a good quality, the twill make being the best.

**COLOURED UNDERWEAR.** White materials are generally preferred for underclothing, but fashion at times takes a fancy for colours, and cambric and silk in pale blue, pink, and heliotrope, and even black, are seen in our fashionable "lingerie" shops, and worn by those with a taste for the fanciful.

Since woollen underwear is now so much worn, a list of the materials employed must of necessity be included.

**FLANNEL.** For the best woollen undergarments fine twill or Ceylon flannel are the usual materials, together with Viyella and some of the finer Welsh makes, with the gauze flannel for summer and tropical wear. These vary from 27 in. to 36 in. in width. It is, however, not advisable to purchase a too fine or close make of flannel, as it washes hard and thick.

**BATH COATING.** This is a kind of flannel very suitable for petticoats, being somewhat stronger and thicker than the usual make. It varies from 45 in. to 54 in. in width.

**NUNS' VEILING.** Those who want something warmer than longcloth and yet not quite so heavy in texture as flannel often select nuns' veiling, which makes up and washes admirably. It should, however, be of a good quality, and is about 44 in. wide.

**SCOTCH WINCEY.** This, a mixture of cotton and wool, is not a new material by any means, but of late years it has come much to the fore for making underclothing, forming the link between calico and flannel. It is smooth in texture and both wears and washes beautifully, as it has not the tendency to shrink which is one of the disadvantages of the latter, and is in many ways preferable to the flannelette which it may be said to replace. The finer makes can almost be drawn through the proverbial ring, but the material can at present only be obtained in Scotland.

**FLANNELETTE.** This has of late years taken a very favourable place in public estimation on account of its cheapness and its comfort for all kinds of underwear. Its inflammability is, however, its disadvantage, and many deaths have taken place through this dangerous quality, particularly among children. There is, however, a "non-flam" variety obtainable, in which the dangerous element has been eliminated, and which we have tried with perfect success. It can be had, like the other makes, in all colours and qualities, and its non-inflammable quality is not impaired by washing.

**COSY COTTON FLANNEL.** Similar to flannelette, being soft and warm, and, like the above material, is, in spite of its woolly texture, made of cotton.

**Trimmings.** With respect to trimmings, Swiss and Madeira embroideries are generally employed, with muslin and jaconet embroideries for finer wear. Coventry frillings are also largely used, and these are manufactured in a great variety of widths and edgings, and only require drawing up by the thread woven in the upper edge before sewing on. They wear admirably.

Lace is also much used for fine and ornamental underwear, Torchon and Valenciennes being the two kinds adapted for the purpose, in the real and imitation varieties. Real Valenciennes is rather expensive, whilst real Torchon is somewhat cheaper, but excellent and good imitations of both can now be obtained which wear and wash well. The round ground Valenciennes is better adapted to underwear than that with a diamond groundwork, being somewhat stronger and better able to resist the onslaughts of the average laundress.

For flannel underwear, flannel embroideries and insertions are employed, as well as Torchon lace, whilst hem-stitched silk frilling adds very much to the daintiness of a flannel nightdress.

Hairpin and crochet work in silk make a charming trimming for flannel wear, for which the worker will find directions in various books on fancy work, as well as the crochet and knitted laces which are much liked by many for the adornment of their undergarments.

Machine-made braids with various kinds of fancy stitching can be bought ready made, and are used in the less expensive kinds of underwear; but in the best class of lingerie, as before said, handwork alone is required. Much practice, however, is needed before this kind of underwear can be attempted; the fine tuckings, insertions, and embroidery on the finest of materials make some of the garments quite works of art.

Ribbon insertions are required for the edges of camisoles, chemises, etc., or any portion requiring a ribbon run through in the more ornamental lingerie. They may be of lace, muslin, jaconet, or longcloth, according to the edging employed in trimming, and vary from three-eighths of an inch to one inch in width.

Veining, or beading, is a very narrow open-work insertion used to unite seams for ornamental purposes in the best underwear.

# PLATING & BOILER-MAKING

Plating Materials. Riveting and Caulking. Angle-iron Smiths' Work.  
Boiler-making. Types and Details of Boilers. Furnaces, Flues, and Tubes

Group 12  
**MECHANICAL  
ENGINEERING**

22

WORKSHOP PRACTICE  
continued from page 2092

By JOSEPH G. HORNER

THE plating department has much in common with the smithy on the one hand, and the boiler shop on the other. The materials used are similar, and to a certain extent they occur in the same forms—that is, bars and rods are used in all three departments. But the smith does not work with rolled plates, nor with rolled sections, such as angles, channels, and beams of H and other forms, each of which is used to a much greater extent by the plater and boiler-maker than are bars and rods. This fact adds to the methods of the smith working on bars and rods, a large number of other details peculiar to the working of plates and rolled sections. And these involve the use of many machines and many appliances which are employed only in these departments.

**Treatment of Plates.** So far as the working of bars and rods is concerned, the boiler-maker and plater adopt the methods of the smith, described in last article. This involves work done at the forge and anvil, such as drawing down, upsetting, bending, welding, and punching, and the tools used are similar. But there is little scope for die forging, the exceptions being the small fittings for boilers, tie-rod eyes, etc. The use of plates and rolled sections, however, involves the cutting up of these to dimensions, shearing, and sawing, planing, punching, drilling, riveting, caulking, and a good deal of awkward welding also—awkward because the rolled sections do not lend themselves to the simple forms of scarf and butt joints as bars and rods do. These trades, therefore, stand apart from that of the smith, and are actually subdivided, much as moulders' work is, between half a dozen groups of craftsmen.

**Iron and Steel.** Plates—whence the trade receives its name—are rolled in thicknesses ranging from  $\frac{1}{8}$  in. to  $1\frac{1}{2}$  in. Most of the work of the shop is done with those ranging from  $\frac{1}{4}$  in. to 1 in. They are received from the steelworks with the edges roughly shorn. These edges in all good work are planed in the shop in a special side-planer before being worked up into place. Also, they are seldom level, and if wanted so, they have to be levelled with hammers, or, in the good shops, in flattening rolls. If they have to be curved, they are treated in bending rolls.

**Rivet Holes.** As plates and sections have to be united with rivets, the rivet holes are either punched or drilled. Punching is done on cold plates, and thus differs from the punching done by the smith on heated bars. It is not done by hammering, but by simple pressure, the punch A [209] being actuated by a cam, or eccentric, or hydraulically. In this illustration, B is the plate punched, the thickness

of which must not exceed the diameter of the punch and should be less; C is the *burr*, or punching, falling out. This is always thinner than the plate. D is the *bolster*, steel-bushed; E is the *stripper* to prevent the plate from rising on the withdrawal of the punch. In bridge and girder work it is usual to punch a number of holes at a time in multiple punching machines, but the common punching machine produces only one hole at a time, so that the plate has to be shifted and reset for each hole.

**Disadvantages of Punching.** The result of punching is severe stressing of the plate in the immediate vicinity of the hole, due to the violence of the detrusive action, and though the evil is not generally apparent at the time, the after results are frequently fractures, due to the extension of the very minute cracks produced immediately around the hole. But if the punched hole be enlarged by a reamer, cutting away from  $\frac{1}{16}$  to  $\frac{1}{8}$  in., the incipient cracks are then removed and no subsequent risk is run. But this reaming occupies time, and so the practice of punching has been largely displaced by drilling rivet holes. For many years punched holes were permitted in boiler practice if they were subsequently reamed, but now it is not allowed in any high-class work. Although it is still retained in much bridge and girder work, even in this the tendency is towards the substitution of drilling for punching.

But another evil nearly inseparable from punching is the overlapping of the holes when plates are punched separately. Thus, 210 shows fair holes when reamed or drilled; but 211 shows holes overlapping slightly. Often in ship and girder work the overlap is much worse than that indicated, amounting to a quarter, a third, or even half the diameter, and then *drifting* is practised, unless inspection is keen. In drifting, a tapered mandrel, or round rod, is inserted and hammered into the holes, pulling and straining the plates, or *drifting* them sufficiently to permit of the insertion of the rivet.

**Riveting.** This is the operation of closing and uniting the plates to each other, and to the rolled sections. All this work was formerly performed by hand hammers; but unless in exceptionally awkward positions, where machines cannot be brought into play, little hand work is done now in modern shops. An immense number of machines, fixed and portable, are employed for closing rivets by power agencies, as water, compressed air, and steam. Not only is the cost lessened by comparison with hand riveting, but the work is more reliable.

When rivets are closed by hand the tails are beaten over with hand hammers, and neatly finished with a *snap* [212], which is struck with a sledge hammer. In machine work the ram slides out and squeezes the tail into shape at once, or beats it down in a few blows.

**Caulking.** The joints of the plate faces are rendered water and steam tight by caulking. That is, the edges are burred up with *caulking tools*, a group of which is shown in 213. The differences in these are: A is the *broad caulking* or fullering tool, sometimes used alone, but more often following the narrower tool B. The objection to the latter is the risk of its bending the plate, and opening instead of closing it, as at side A in 211, where the nick made by the caulking tool is also indicated. In 213, C is a tool used round rivet heads in conical tubes, D is a heavy tool which is struck by the sledge. Caulking is now largely done by pneumatic hammers, which operate much more rapidly than the handworker.

**Rolled Sections.** The rolled sections which fill so large a place in the plating shop and to a less extent in the boiler shop include angles, channels, joists, and tees [214, black sections], the functions of which are primarily as a means of union for plates, or as bracings. But they are also used largely as elements from which beams, stanchions, and columns are built up cheaply. The number of combinations thus available, and the range of their dimensions run into many hundreds; in fact, to illustrate and describe them and their functions would occupy a goodly volume. Of the sections themselves shown in black [214] (against bending blocks, to be noted presently), the most common is the *angle* A. The flanges are equal as shown, or unequal in width. They are *square throated* or *round backed*, and *bulbed*, *right angles* [A] or *acute* or *obtuse* [B], and all in a wide range of thickness and width of flange. The *channel* C is made in a similar range of sizes, and with different proportions of flanges and web. The *joist*, *beam*, *girder*, or *H-section*, D, is of extensive utility, and is often in itself a cheap substitute for beams built up of plates and angles, or of plates, angles, and bracings. The *tee* section, E, is equally useful. A variation on it is the *bulb tee*, used much in shipbuilding. The *rail* section, F, is used to a considerable extent in some classes of plating for civil engineers, especially in the form of old rails.

**Angle-iron Smiths' Work.** The operations by which these rolled sections are prepared for the plater are largely done by men distinct from the platers, the *angle-iron smiths*, whose work lies wholly at the forge. They bend and weld where welding is done, and flange plates, if this be done at the forge, though most of it is now appropriated by flanging machines. The equipment required for this work includes a large variety of heavy cast blocks, besides the usual appliances of the forge, which are nearly common with those employed in the ordinary smithing. Sections are generally now cut off to a circular saw (*cold saw*). The welds

are made almost invariably of the *glut* form, and work is done in detail at successive heats, since it is impossible to weld simultaneously round two webs of, say, an angle.

The blocks shown in hatched section in 214 are examples of bending blocks, each suitable for the rolled section shown lying against it. The shapes imparted in plan view may be anything, being made to suit the curve or bend required, such as circular or angular, or embodying combinations of curves and straight portions. The holes seen in the blocks are for bolting or cottaring them down to the *block* [215], on which the operations of bending are commonly done, the case of special blocks excepted. The large number of holes cast in this block permits of bolting anything down upon it for secure fixing. Frequently two or three such blocks, but without holes, are bolted together edgewise to form one large block to be used for levelling plates upon, a subject to be noted presently.

**The Glut Weld.** This form of weld was illustrated in the article beginning on page 2983. If a glut weld has to be made in an angle section, each side of the angle is done separately at successive heats. It is necessary first to scarf the ends, which is done by cutting them while hot with a hot sett. The ends are then brought into opposition and retained with clamps, and the joint portion put into the fire and brought to a welding heat.

The glut is also heated in the same fire, or in one adjacent. Both are taken out at the same instant to the anvil, and a few blows with a hand hammer effect the weld. If the joint be for an angle, a second heat has to be taken for the other web. Only after the welds are made is there any attempt to impart a neat finish to the surfaces, for which another heat may or may not be required. It is not judicious to do much hammering on iron or steel after the metal has lost its redness. The results are more serious in the case of steel than of iron, consisting of a marked reduction in ductility.

If a long glut weld has to be made, it may often have to be done in more than one heat—say in lengths of 5 in. or 6 in. at a time. A separate length of glut is used at each section. Gluts are used not of the length of the weld to be made, but 3 ft. or 4 ft. longer, to afford a length to be held in the hand (a *porter bar*). The supplementary portion is cut off after the weld is made.

**Welds of Corners.** In plated work a good deal of welding of corners is rendered necessary because rolled sections cannot be bent at right or acute angles on account of the crumpling, or extension of the web that lies flatwise in the plane of bending. This subject of crumpling and extension on opposite sides of the neutral axis was explained in last chapter. It is necessary, before welds can be made in any of the sections shown in 214, to cut away in some cases, or to insert gluts in others. Thus, in 216, if an angle bent inwards has the web on the inside, then a portion must be cut out as at A, and the ends overlapped, B, C, and welded. The bending of an uncut web would produce much crumpling

up of the metal. An alternative device to that at A is shown in D, where a notch is cut, with a projecting lip, and when the angle is bent the lip overlaps and is welded. An open space is left which is filled by welding a punched burr there. F shows one method of securing an angle on a block during the act of welding it. If an angle, when bent, has its web on the outside, then a portion must also be cut away, and a filling-in piece inserted. The reason is that the bending of an uncut web would produce either extreme attenuation of the metal or its actual rupture. The latter would occur when the tensile stress exceeded the tensile strength of the material. And what would occur in angles also applies to tees, channels, and other rolled sections. G shows the notching of such an angle, H its appearance when bent, and J the same ready for welding. A flat piece, *a*, is laid on to cover the joint, being attached to a porter bar *b*, which is cut off after the welding is completed.

**Boiler-making.** This is a trade which has more in common with the work of the plater than of the engine smith. It involves plating, and the work of the angle-iron smith, as well as some of the elementary processes carried out by the engine smith. The materials for boilers occur chiefly in the shape of rolled plates, angle sections, rivets, and stays, which require different treatment from bars and rods forged at the anvil. The range of operations involved includes those of the smithy, but extends much beyond them. Besides this, the types of boilers vary so widely that each great group involves the employment of machinery more or less specialised and requires the services of men who are specialists.

The boiler-maker employs steel plates, which have to be levelled, and bent, drilled, and riveted. He does not use so many rolled sections as the plater, his requirements being limited to angles and tees chiefly. Machine riveting has displaced hand riveting with him as it has in the plater's work. As these trades occupy so much common ground we shall not repeat statements that have been already made, but give attention to a few matters that relate to boiler work only.

**Difference Between Boiler Work and Plating.** Put in a nutshell, boiler work differs mainly from plater's work—i.e., bridge and girder and cognate structures—in the fact of its having to withstand the effects of high temperatures and high pressures. These are the two conditions that render boiler-making a trade apart from plating, notwithstanding that it is so closely allied to that and smiths' work.

Dock gates, penstocks, the walls of tanks, and hydraulic fittings have to withstand severe pressures which are often as great as those in steam boilers. But the conditions are not identical between the steady, solid pressure of water and the pressure of elastic gaseous steam. Rupture in the first simply means leakage, nothing more; in the second it involves terrible destruction, so that in boilers the materials must generally be of better quality than those

used for plating. Shearing and punching as finishing operations have long since been abandoned, and very careful caulking is essential to make steam-tight joints without injuring the plates. Besides this, there is the vast amount of practical detail involved in furnace construction and in the precautions taken to avoid as far as possible the effects of expansion and contraction of boiler parts due to heat, which have destructive results on joints, seams, flanges, and plates. Connected with this is the subject of *staying*, or affording just the right amount of support to plates much too weak in themselves to resist high pressures.

**Details of Boilers.** The principal elements in boiler construction are the following: the shell, the furnace, or fire-box, the tubes, the combustion chamber, the smoke-box, and the fittings. With work outside the boiler, such as its seatings, brickwork flues, chimney, mountings, including the furnace doors, mechanical stokers, and economisers, when such are used, the boiler-maker is not concerned. His work ends when the actual boiler is ready to be put into its place. As we cannot describe in the space available the construction of the different kinds of boilers, the remarks to follow will be generally applicable to any boilers in which the elements named occur. Three boilers are illustrated as examples on which to hang the remarks to follow—namely, the *Cornish* [217], the *vertical* [218 and 219], and a *return-tube marine (Scotch) boiler*, with a single furnace [220 and 221].

**The Shell.** This signifies the outer portion of the boiler [A in 217-221], in which the water and steam are confined, and which is subject to pressures tending to burst it. It is termed the *shell* in all boilers except the locomotive; in which it is the *barrel*. In horizontal boilers [217, 220 and 221] the longitudinal axis of the shell lies horizontally. In vertical ones [218 and 219], the axis lies vertically.

**The Shell Plates.** Only in a vertical boiler of small dimensions is the cylindrical portion of the shell rolled in a single plate. In the larger verticals, and in Lancashire, Cornish, marine, and locomotive types there are two, three, four, or five rings of plates required to make up the length. But except in the large marine boilers, a single plate is now generally used to bend each ring from, instead of three plates as was formerly the practice. This change is due to the fact that plates can be manufactured in larger sizes in steel than in iron. From this results the important advantage that the longitudinal seams of shells are reduced from two or three to one, and a troublesome source of grooving thereby removed. Not only can seams be kept away from the bottom of the boiler where deposit is liable to occur, but having one seam only, made with double butt straps, the circular shape of the shell is retained, which was not the case when longitudinal lap seams were common.

The edges of shell plates are planed in a plate-edge planing machine, and rolled to the circle

**DETAILS OF BOILERS**  
 218 and 219. Vertical boiler    220 and 221. Return-tube marine boiler    222. Action of bending rolls  
 223. Various riveted joints

in bending rolls, having one housing removable to permit of sliding the complete cylinder off endwise. The essential action of the rolls is seen in 222. By the adjustment of the upper roll, A, relatively to the lower ones, B, curves of varying radius can be produced.

**The Riveted Seams.** There are two kinds of seams: the *longitudinal*, or those which run lengthwise of the boiler, and form the joints of the rolled rings, and those which run circularly round the boiler—the *transverse* seams—and unite the rings to each other. As calculations show that the latter need have only half the strength of the former, single riveted [223, A], or double riveted lap seams [223, B] are used for the circular joints. But the longitudinal seams are seldom lapped, and then only in boilers for low pressures, because a lap, in a shell required to be truly circular, breaks the continuity of the circle. All such seams therefore should be made with *butt straps*—that is, narrow strips riveted against the face or faces of the shell. These are *single*, *double*, or *treble riveted*, the rows of rivets being doubled or trebled for the higher pressures. C is a single-riveted single butt strap joint, D is a double-riveted single butt strap, and E a double-riveted double butt strap, which is generally employed when pressures exceed about 100 lb. to the square inch. F shows double butt straps on a circular shell, and G is a plan view of one strap shown in connection with two circular seams, single riveted; 224 shows a longitudinal lap seam, double riveted, and a circular lap seam single riveted, together with the thinning and spreading of the corner, adopted when three plates have to cross or overlap.

The butt straps must have both edges planed ready for subsequent *caulking*. Caulking on roughly-shorn edges is now never permitted in boiler work. The rivet holes are now generally drilled with all the parts in place. Formerly they were drilled (or punched and reamed) before the plates were bent. But there are a number of special drilling machines now designed for boiler-shop use, in which the rings and butt straps, being held temporarily with tack bolts, drill the holes in place, and remove the *arises*, or sharp wire edges, from the holes. The shells are then riveted up by machines which close the rivet tails by hydraulic or pneumatic pressure, the boilers being slung up in a crane during this operation.

**The Boiler Ends.** A shell is not complete without its ends [B in 217 and 221]. These ends have holes either for furnaces or fire tubes. They are prepared and riveted to the shell and to the furnace ends in the case of Cornish and Lancashire and marine boilers. These ends must be perfectly flat. The methods of flattening them are precisely those adopted in levelling all plates used in the plating and boiler shops. Mention has been made of this as the fact whence the levelling block [215] derives its name, and this is the place to offer some observations on the very important operation of flattening plates.

When plates come from the rolling mills they are not flat (unless ordered so), and part of the

work of the boiler-maker or plater lies in levelling them.

**Levelling Plates.** This is done either on the block, like 215, but plain, with hammer blows, or between rolls—*flattening rolls*, often termed the *mangle* in the shops. The first is not so good a method as the second, and it is much more tedious, but it is an operation requiring much skill and experience. In hammer flattening the blows are never delivered on the area that is actually bent or buckled, but on those adjacent. The reason is that buckle is due to an extension of the fibres, and hammering there would extend them still more. But hammering on the encircling metal extends that, leaving the buckle free to straighten itself therein. Though plates can be made perfectly level in this way, yet much time is occupied. The operation is noisy, and excessive hammering tends to induce a brittle state in the metal. When plates are flattened in the rolls, these differ from the bending rolls only in the number of rollers used. There are three in the first, usually seven in the second—four below and three above—or vice versa. But it is clear that by the passage of a plate between top and bottom rolls arranged with the centres of each alternating—that is, the centre of every roll falling plumb between a pair above or below—the effect is to squeeze and level all inequalities. Two passes, or three at the most, suffice to straighten the most crooked plates within five minutes, against, perhaps, an hour occupied in hammer levelling.

**Flanging Plates.** Formerly the boiler ends were united with internal rings of angle iron to the shell. Now the practice is to flange the back plate, turning the flange within the shell, and to unite the front plate with a ring of external angle iron [217], or by flanging. Marine (Scotch) boilers have both front and back plates flanged inwardly [221] and sometimes outwardly. Vertical boilers [218 and 219] have their *crown plates*, B, flanged inwardly, and occasionally outwardly. The *furnace crown*, C, is also flanged. The bottom end of a vertical boiler is formed by the *foundation ring*, by which the fire-box is united to the shell, or the fire-box is flanged outwardly [219 and 225].

**Reasons for Flanging.** Flanging has displaced angle-iron joints—first, because the latter were a frequent cause of grooving; secondly, because steel is more readily flanged than iron was; thirdly, because machines have nearly displaced hand flanging. The boiler-maker often has to do hand flanging in the smaller shops which are destitute of machines, though these usually now send their flanging to be done in the big works. When effected by hand, the operation is rather tedious, so that flanging a plate might occupy two or three men a day, against, say, four men half an hour with a press, in which the actual turning over of the flange does not occupy more than a minute. One of these presses with a plate *in situ*, as just flanged, was illustrated in the course on Applied Mechanics, page 1221, 154.

Press flanging is also better from the point of view of homogeneity of the plate. When done by hand work, short heats of 10 in. to 12 in. have

#### DETAILS OF BOILER CONSTRUCTION

224, Thinning corners 225, Flanged fire-box 226, Adamson and Rowling furnace seams 227 and 228, Fire-box of locomotive boiler 229, Screwed stay 230, Girder stays 231, Tube ends

to be taken in succession, and that length of flange is hammered over a block at a single heat; so that the work has to be moving between the fire and the bending block several times before the circle is completed. In a press the whole of the flanging is done at one heat, marine boiler fronts excepted, and the danger of working at the blue-black heat incidental to hand flanging is avoided, because the flange is still at a good red when finished. Consequently, when ends are flanged by hand they must be *annealed*, an operation which is not necessary with press work. The radius of the flange is important. A large radius gives more elasticity to the end than a small one does, with less liability of grooving.

**The Furnace.** The furnace, as distinct from the fire-box—the functions of both, however, are alike—denotes the tubular form (*furnace flue*) used in internally fired boilers. These include the Cornish [217, C] and Lancashire, the marine [221], and allied forms having one, two, three, or four furnaces arranged side by side longitudinally. The furnace of the vertical type [219, E] is a *fire-box* and that of a locomotive is similarly named. The furnaces in 217 and 221 are riveted to the front and back plates. The *fire-grate*, D, *ash-pit*, E, and *bridge*, F, occupy the four to five feet of length next the fire door, and the space beyond forms a *combustion chamber* in which the gases are burnt.

The furnace is subject to pressure from without, and is thus in a far less favourable condition than the shell. It is also liable to suffer by the accumulation of calcareous and other hard deposits which come from the water over the fire, and lessen the transmission of heat from the fire to the water, and which also, by causing overheating, increase the natural weakness of the furnace to resist collapse.

**Furnace Design.** There is a large amount of interesting history in connection with the development of boiler furnaces, ranging from the plain or hooped furnaces, which were the causes of numerous accidents, down to the present forms, with the *Adamson seam* [217 and 226 A, B, C], the *Bowling hoop* [226, D, E], and other allied designs, and the *corrugated* types. The net result may be summed up thus. Instead of a long weak tube having no adequate support away from the immediate vicinity of the ends, the length is divided into several short, practically independent sections, the lengths of which are determined by the positions of the flanges, or hoops.

In 226, A shows a portion of a furnace flue, partly in external view, partly in section; B shows the Adamson flanged joint, or seam, enlarged in section; C is a later alternative in which the flue sections are of different diameters, with the object of improving the efficiency of combustion of the gases, and giving greater longitudinal elasticity; D shows a Bowling hoop, partly in external, partly in sectional views, and E is an enlarged section through the

riveted, which proved a source of danger. They are now invariably welded. Flanging of the ends [217] is also substituted for rings of angle iron, unless, as in some marine boilers [221], the end plate is flanged inwards to meet the flue. The flanging of furnace flues is done in a special machine, which rolls over a flange in about a minute. If Bowling hoops are used, these are rolled also. The drilling and riveting are done in machines designed specially for this work. In some the flues are held in a vertical position, in others in a horizontal. There is really no hand work in the manufacture of furnace flues in up-to-date boiler shops. The exception sometimes is the welding up of the longitudinal seams. But generally that is done under a power hammer, the tube being moved under it along a mandrel. Lap or glut welds are both used in these.

**Galloway Tubes.** Furnaces have *Galloway*, or *cross-tubes*, G 217 being the first-named, and D 219 the second. These are made and inserted before the furnace lengths are riveted at the circular joints. The tubes are prepared by welding and flanging, by methods similar to those employed in making the flue lengths. The longitudinal joint is either glut or lap welded. The flanges are still often turned by hand, by hammering them in short sections, followed by annealing. They are also turned in special machines. They are generally riveted into the furnace flues by the flanges. But sometimes welding is adopted, although less frequently than formerly. Then there is no flanging done, but only an upsetting of the ends sufficient for welding. The general objection to welding is the difficulty of removing a tube for the purpose of renewal or repair. When a tube is flanged, the rivets as well as the flanges are usually caulked with the tool C in 213.

**Union of Furnace to Shell.** When the furnace has been riveted up, it is inserted into the shell. Generally it is riveted to the back end plate first, and then the front end plate is brought up to it and riveted, and the diagonal stays are riveted at the same time. Here the work of the boiler-maker ends on the furnace flue. The furnace-doors, fire-bars, and bearers are inserted by another set of men after the boiler proper is completed. In the marine or Scotch boiler the furnaces are generally strengthened by corrugations, and divided by Adamson seams. They are riveted at the front end to the flat plate there, and at the back to the tube plate of the combustion chamber.

**The Fire-box.** This is the term given to the furnace used in a locomotive type of boiler, and in verticals [219, E], although the two forms differ. In the locomotive [227 and 228] it is a nearly rectangular box; in the vertical type, [219, E] it is a frustum of a cone. In both, the fire is at the bottom of the box on the grate-bars, and the flame occupies the remainder. In the locomotive the hot gases pass through the horizontal fire-tubes to the smoke-box; in the verticals they pass up through the uptake, F, directly to the chimney (not shown), placed above the uptake.

**Flanging** is the only means of union adopted in locomotive fire-boxes, having long ago displaced angle-iron joints, found in other kinds of boilers. Hand flanging has also been superseded by that of the press, fitted with massive dies of cast iron. A press turns the flanges at one heat in about a minute.

**Locomotive Fire-box.** The fire-box [227 and 228] comprises the *tube-plate*, A, and *back plate*, B, both flanged inwards towards the fire-box space, and united by the covering or *wrapper plate*, C, bent round in one sheet to form the top and flanks of the fire-box. This is the fire-box or actual furnace. But it has to be united to the boiler shell, or barrel, and this is done by an extension of the latter termed the *outer fire-box*, though it is a part of the water and steam space. At the front (viewed from the footplate) the back plate D, in which the fire-hole is cut, is flanged inwards and con-

enlarged view of a stay and its two plates is given in 229. The sides and back of the inner and outer boxes are similarly united with screwed stays. The top of the fire-box is stiffened with *bridge or girder stays*, indicated in 227. A more detailed drawing of a slightly modified design is given in 230. The stays are of cast steel, and are of the *sling type*.

The holes for the rivets and for the screwed stays are all drilled after the several parts are in place, portable machines having preference. The holes for the stays [229] are screwed with special taps, long enough to reach from the outer to the inner plates. All this work is done by a gang of men distinct from those who make the barrels and flange the plates.

**Fire-box in Vertical Boilers.** This is a simple construction [219, E], by comparison with that of the locomotive. It is circular in horizontal section, and is therefore rolled in

232. TUBE EXPANDERS 233. SCREWED-BAR STAY 234. MANHOLE 235. STEAM DOME  
236. HYDRAULIC FLANGER (Fielding & Platt, Ltd.)

nected to the barrel first by a wrapper plate, E, riveted to the flange of the back plate at one end, and to the barrel, and throat plate, F, at the other. The throat plate is double flanged: forward to meet the outer fire-box plate, and backward to embrace the lower part of the barrel. Between the back plate, the throat plate, and outer covering plate, the fire-box, already riveted up and caulked, is inserted, and united to all three plates at the bottom by a *foundation ring*, G, of rectangular outline in plan, and rectangular cross-section. Below this comes the *ash-pan*, H.

**Staying.** As all the plates are flat, they are enabled to resist the steam pressure only by virtue of staying. The smoke tubes stay the upper portion of the tube plate. Its lower portion and the area of the throat plate are mutually connected and stiffened with screwed stays, seen surrounding 227. and 228, while an

bending rolls. In vertical section it forms the frustum of an extremely tall cone, the amount of coning on the height of the box being from 3 in. to 4 in. only. The fire-box shell is sometimes welded, but more often riveted, frequently with a lap joint in small boilers, but always in larger ones with a butt joint, and either single or double butt straps. The fire-box crown is either a flat or a dished (convex) plate, C, flanged downwards and riveted within its shell. Cross tubes, D, are nearly invariably fitted, similar to those in Cornish and Lancashire boilers, except that they are more often parallel than coned. They lie horizontally, or at a slight angle with the horizontal. Holes have to be cut in the fire-box shell to receive these tubes.

**Fitting to the Shell.** In some other details of these furnaces practice varies. Sometimes the bottom end is slightly flanged outwards

237. RIVETING AND CAULKING A LANCASHIRE BOILER

to meet a foundation ring, by which the fire-box is united to the outer shell. Sometimes there is no flanging done, but the plate is plain, meeting the ring as in the locomotive [227]. Often the ring is omitted, and the flanging meets the boiler shell as in 219 and 225. The attachment to the shell around the fire-hole door generally involves a flanging outwards as at G [219]. In all but the smallest boilers the fire-box is united at intervals to the shell with screwed stays [218 and 219]. But in the smaller ones the foundation ring, the uptake, and the fire hole are the only plates where union is effected.

#### The Smoke Tubes.

Smoke tubes [220, 221, 227, and 231] are inserted after the boiler has been riveted up, and so far completed. The holes for the tubes will have been drilled in the plates after the flanging and previously to riveting up, the positions of the holes being controlled by holes in a templet which guide the drill. The tubes therefore fit in a smooth, plain hole, in which, too, they must make an absolutely steam-tight fit. It would be improper to try to produce that fit by hammering or percussive action of any kind, therefore the tubes are squeezed by an expanding movement, and pressed tightly into their holes. Tools termed *tube expanders* are used for this work, operated by the workmen's hands. The fit is so tight that this would generally be sufficient to prevent any slip and movement of the tube plates.

**Inserting Tubes in Multitubular Boilers.** When fire tubes are used, as in locomotive, and marine (Scotch) cylindrical boilers, the place of the furnace flue of the Cornish boiler [217] and of allied types is taken by the tubes and the fire-box, as in the locomotive boiler, or the furnace is shortened and the tubes return over it, as in the marine boiler [221]. These differences involve some variations in the method of working.

In the locomotive the tubes are fitted into the fire-box plate at one end, and the smoke-box plate at the other, which bound the water space traversed by the tubes. The fire-box

plate is an integral portion of the fire-box or furnace, which also is surrounded by water spaces enclosed between it and the shell of that portion of the boiler sometimes termed the *outer fire-box* to distinguish it from the cylindrical barrel. The fire-box plates are generally of copper, and the tube plate is thicker than the rest to afford a good bearing to the ends of the tubes. Before the tubes are inserted, the fire-box is riveted into the shell with the screwed copper stays. The tubes, of brass, Muntz metal, copper, iron, or steel, are fitted generally by expanding.

**Beading and Ferruling.** Expanding is generally followed by *beading*, which means turning over about  $\frac{1}{4}$  in. of the end of the tube, projecting beyond the face of the plate. This is done by percussion, or by pressure, using a tool having a portion corresponding with the shape of the bead. Often in boilers other than marine boilers, the tube ends are *ferruled*—that is, short lengths of tube are inserted within the expanded ends, and also expanded therein. Fig. 231 A illustrates a tube inserted in its plate and expanded simply. At B a ferrule has been put in, and expanded within the tube; at C a tube has been beaded in addition to expansion. D shows the Admiralty pattern of ferrule, inserted in the tube

with the object of preventing leakage from the tube ends, and burning, in the closed stokehold system of using forced draught. Fig. 232, A, shows how beading is frequently done by simple hammering of the beading tool against the end of the tube. It is, however, often combined with a tube-expanding tool.

**Tube Expanders.** The tube expanders used include two or three well-known types, the action being either the thrusting outwards of three rollers *a, a, a*, [232], within the tube, effected by the turning and thrusting of a tapered mandrel, *b*, against the inner edges of the rollers, which is the more common method (the Dudgeon expander), or by the driving outwards of segments of a ring by a tapered mandrel.

Besides the holding power of the tubes,

239. DRILLING BOILER FURNACES

240. UNITING FURNACE FLUE AND END PLATE

Additional security is ensured by the insertion of a few special stay bolts, from six to a dozen in number, screwed at the ends and double-nutted [223 and 221, H], within and without the plates, or by the insertion of stay tubes, as in marine boilers. The diameter of the bottom of the threads in these must not be less than that of the body of the bolt or tube. The end plates in Cornish and Lancashire boilers are stiffened with *gusset stays* [217, J]. *Bar stays* also connect the crowns in vertical boilers [219, H].

**Order of Operations.** In these and other fittings, regard must be had to the sequence of operations. Diagonal stays should be riveted to shells before the end plates are brought up into position. An uptake of a vertical boiler is riveted to the furnace crown before the latter is inserted in the shell. Caulking of internal seams must be done before furnaces are inserted. Unless attention be given to these and cognate matters, awkward and impossible jobs would result.

### The Combustion Chamber.

This is the term given specifically to the space at the back of the furnace flues in a marine Scotch boiler [221, G]. The work is that of the plater, involving flanging, beading, and tubing, the fire-tubes bringing the products of combustion from the chamber to the front of the boiler (*return-tube type*).

**The Smoke-box.** This is the chamber into which the tubes of the locomotive discharge, being underneath the chimney. It is connected to the boiler by the front tube-plate, which is riveted to the end of the barrel with a weldless steel angle ring, encircling the end of the barrel, and shrunk on and riveted. This is flanged

towards the smoke-box to receive the wrapper or covering plate, which is attached to the front plate with an angle iron. The front plate has a hole cut for the smoke-box door, which permits examination of the tubes to be made. The chimney base is made by stamping, and is riveted on the top of the covering plate over the hole cut for the purpose. The chimney is rolled and riveted down the vertical seam, and riveted to its base.

**Fittings.** Fittings include a number of articles which the boiler-maker has to attach, and in many cases also to make. They are mostly comprised under the term *seatings*, shown on top of 217, and below H; that is, pieces of an intermediary character, which re-

ceive certain fittings, as safety valves, stop valves, blow-off cocks, etc. But manholes and domes are not intermediate, but complete fittings in themselves.

The necessity for intermediate fittings is that it would not be practicable to bolt a safety or a

241. COMBINED PUNCHING AND SHEARING MACHINE

stop valve directly to the boiler plating, because of the impossibility of making a close steam-tight fit in that way. And whenever repairs had to be effected or renewals made, the removal and replacement would be equally troublesome. But if a seating be prepared fitting to a boiler, and having a face planed level for the article to be mounted thereon, all trouble is avoided. Another important point is that it permits the seating to be riveted to the boiler—the best form of union suitable for direct attachments to boilers—and the actual mounting to be bolted to the seating, thereby being more readily detachable than a riveted seating.

**Materials in Seatings.** These seatings are made either of cast iron, or more properly of mild steel, or wrought iron. The advantages of the latter are immunity from risk of fracture, and that the edges can be caulked, which is not possible with cast iron. When cast iron is used, steam-tightness is secured by bedding them on a film of red lead, or by inserting a sheet of wrought iron (*caulking ring*) between the face of the seating and the flange of the mounting. The edge of this is then burred up with the caulking tool.

**Manholes and Domes.** The case of manholes and steam domes is different, because they have no seatings, but are riveted directly to the boiler. A few years ago, manholes were invariably made of cast iron, or cast steel, and then caulking rings of wrought iron were necessary. But so many accidents occurred in consequence of the fracture of the cast iron that manholes of rolled steel have superseded them [234]. These are made very similarly to the flue lengths of furnaces, being rolled, welded, and flanged. They are also much lighter than cast iron. Steam domes are also made by welding and flanging, though a flanged ring is often substituted [235].

When these and manholes are attached to boilers, the openings cut in the boiler are a source of weakness, and would be dangerous but for the practice of reinforcing the hole with a strengthening ring inserted within the boiler and encircling the hole [234 and 235, A]. The rivets which attach the mounting also pass through the ring and so unite the flange, the boiler plate, and the ring at once.

**Geometry.** There is a considerable amount of geometry involved in the marking out of plates for boiler making. Generally, this work is done by men originally boiler-makers, but whose duties are now restricted to the work of marking out (*templet makers*). The problems are those common to sheet-metal working generally. They will be found treated geometrically in *Practical Geometry*, and their application in *Drawing for Sheet Metal Workers*.

**Testing.** The testing of boilers is done by hydraulic pressure, generally at about double the working pressure. The boiler is nearly filled with cold water first, and then the test pressure pump, fitted with a gauge, is set to work, until the limit imposed is reached. Then the pressure

is allowed to remain for an hour or more, and close observation is made to see if any leakage occurs at seams or rivets. Any such localities are marked with chalk, but are not caulked until the pressure is removed, because that would distress the boiler. If necessary, the pressure is reimposed. The steam test often follows, but it is not always insisted on. If used, it is about equal to one and a half or one and a quarter times the working pressure. Its advantage is that it tests the boiler under actual working conditions. The advantage of the hydraulic test is that no accident occurs should leakage be present—a little water spurts out, and the pressure is off.

Boiler-making is thus a trade embracing very diverse practice, which is divided between different shops and subdivided in the shops. So that we have men grouped as *templet makers*, *planer hands*, *rollers*, *angle-iron smiths*, *flangers*, *drillers*, *riveters*, *tubers*, besides unskilled labourers, holders-up, etc.

Fig. 236 shows a hydraulic flanger, pressing over the flanges of a furnace-mouth between a die on the table and one attached to the two rams. The latter are used independently for some classes of bending.

**In the Shops.** In the photograph [237] two operations are seen in progress on a Lancashire boiler, in the shops of Ruston, Proctor, & Co., Ltd., Lincoln. The men at the extreme left are working a hydraulic riveter, engaged on the end plate, while the man at the extreme right of the boiler is caulking with a pneumatic hammer, the supply pipe of which is seen lying on the ground. A small set of plate-bending rolls is shown in 238 (Francis Berry & Sons, Sowerby Bridge) driven by belt pulleys and gearing. The top roll is extended, and supported by an extra bearing, so that the roll is held level while the right hand bearing is swivelled to one side, enabling a plate to be slid off endwise, after it has been bent into cylindrical form. The two large handwheels are for raising and lowering the top roll for different curvatures. In 239 a marine boiler with four corrugated furnaces is being drilled with machine seen inside the top left hand furnace. This boiler is one of the set for the "Oceanic," constructed by Harland & Wolff.

Hydraulic riveting with a fixed machine is illustrated in 240, the operation being that of uniting the end plate to the Adamson flue, which is supported by the overhead traveller meanwhile. This is also from Messrs. Ruston, Proctor's practice.

One of the most useful machines in the boiler shop is that shown in 241, a combined punching and shearing machine (Francis Berry & Sons). It is driven by the electric motor seen on the top. At the left-hand end shearing is done, at the right punching, while at the centre a special pair of jaws are fitted for shearing angle irons, which cannot be done with straight blades like plates and bars.

*Continued*

# A SHORT DICTIONARY OF TERMS IN SMITHS' WORK

**ACCUMULATOR**—A vessel in which water is stored under pressure for the operation of hydraulic presses.

**Adamson Flanged Seam**—A joint in the furnace flues of many horizontal boilers, formed by flanging the ends of the flue lengths, and riveting them together through an intermediary caulking ring.

**Air Furnace**—A reverberatory furnace, using the natural draught of a chimney.

**Angle Beveling Machine**—A machine fitted with rolls for imparting various angles to the webs of angle sections.

**Angle Iron, Angles**—Rolled sections of iron and steel having two webs at right or other angles with each other.

**Angle-iron Furnace**—A reverberatory furnace used for heating angles.

**Angle-iron Shears**—Shears of V-shape, used for cutting off angles.

**Angle-iron Smith**—A workman whose duties are confined to the preparation of work done at the forge.

**Annealing**—The heating and slow cooling of iron and steel after work has been done, in order to restore ductility and homogeneity.

**Annealing Furnace**—A reverberatory furnace used for the purpose of annealing.

**Anvil**—The block upon which forgings are treated. The best are of wrought-iron, welded up, and steel-faced. Many cheap anvils are produced by casting.

**BANKING UP**—Making up a forge fire with green coal or small coal, damped with water.

**Bars**—The round, or rectangular sections in which iron and steel are rolled. They are *rounds, squares, and flats*.

**Beading**—The burring over and rounding of the ends of boiler tubes.

**Beading Tool**—A drift-like tool used for beading boiler tubes.

**Beak Iron, or Bick Iron**—The conical projection of an anvil.

**Bending Blocks**—Blocks of cast iron variously shaped to serve for bending bars, sections, and plates by.

**Bending Rolls**—Machine rolls used for bending large plates in. The rolls have their axes either horizontal or vertical.

**Bessemer Steel**—Used in tyres, rails, and for many forgings.

**Beveled Iron**—Flats having one or two edges beveled.

**Blazing Off**—The burning of an oil or fat having a known flash-point, which corresponds with a temperature suitable for tempering springs and some other articles.

**Bleeding**—The presence of red rust on the plates of boilers, which indicates corrosion within the plates.

**Blisters**—A defect in plates due to the entanglement of slag or scale in the bloom previous to rolling.

**Blue Heat**—Corresponds with a stage between a low red and a black heat, at which, if severe work is done on steel and iron, serious loss of ductility and strength results.

**Boiler**—The vessel in which steam is generated by the action of heat.

**Boiler Fittings**—Sundry parts which have to be attached to a boiler: as doors, seatings, bridge, fire-box, &c.

**Boiler Flues**—The furnaces, or the brickwork, or smoke flues.

**Boiler Flue Flange Drilling Machines**—Machines for drilling the rivet holes in the flanges of Adamson seams.

**Boiler Prover**—A force-pump, with gauge, used for testing boilers by water pressure.

**Boiler Scaling**—Chipping the hard deposits from the interiors of boilers with a scaling hammer.

**Boiler Shell**—The outer body, as distinct from the furnace.

**Boiler Shell Drilling Machines**—Machines for drilling the rivet holes in shell plates, generally after the plates are all fitted in series.

**Boiler Shop**—The shop in which boilers are made. Its equipment consists chiefly of heavy machinery and forges.

**Boiler Smithy**—The department in which the forged work is done by the angle iron smiths.

**Boiler Stays**—Rods or tubes used for reinforcing the flat surfaces of steam boilers.

**Boiler Tubes**—Fire tubes in the locomotive type; water tubes in the water-tube type.

**Booster**—A ring upon which holes are punched, and through which the burr is pushed.

**Bolt Machine**—A forging machine in which bolts are formed by rapid reduction in concave dies.

**Borax**—Used as a flux in welding steel and iron.

**Bosh**—The water tank in which the smith cools and quenches work.

**Bossing**—Forming bosses on forgings.

**Bowling Hoop**—An expansion ring of arched section used in furnace tubes.

**Box Girder**—A girder having four sides enclosing a hollow rectangle.

**Bracings**—Arrangements of bars in plated work which change the direction of stresses, so reinforcing otherwise weak members.

**Brands**—Trade marks used to denote qualities of iron and steel, and the houses from which they are sent.

**Brick Arch**—The arch in a locomotive fire-box which deflects the gases backward before they pass into the fire tubes.

**Bricked-up Fire**—A hollow fire enclosed with bricks, in which rolled sections are heated for welding, and by which they are prevented from contact with the fuel.

**Bridge**—The barrier placed at the back of the fire-grate in a horizontal boiler to promote combustion.

**Buckle**—A state of unequal tension in plates.

**Bulb Sections**—Bars, angles, and tees, having one edge thickened or beaded.

**Bulldozer**—A machine which presses work into dies by means of a reciprocating ram.

**Burnt Iron and Steel**—Metal which has been overheated at the forge, and injured thereby.

**Burr**—The piece removed by a punch.

**Butt Joints**—Joints that abut by their edges, and then are covered by and riveted through butt straps.

**Butt Welding**—The welding of joints brought into simple opposition.

**CASE HARDENING**—Imparting surface hardness to iron and steel by prolonged contact with bones, leather, charcoal, or ferro-prussiate of potash, at a red heat.

**Caulking**—Burring up the edges of riveted plates with a caulking tool to render the seams watertight.

**Caulking Ring, or Strip**—Wrought-iron or steel inserted in a joint to provide for caulking against.

**Channels**—Rolled sections the sectional form of which is that of three sides of a rectangle.

**Chipping Chisel**—A tool used for cutting iron and steel while cold.

**Chisels**—Used under the name of cold and hot sets.

**Chisel Rod**—Rod from which cold chisels are made, being of the same section as the chisels.

**Clamps**—Used for holding pieces of work temporarily.

**Closing**—Turning over the tail of a rivet, or the jointing of a weld.

**Cold Chisel**—A *chipping chisel*.

**Cold Saw**—A circular saw used for cutting off bars and rolled sections without heating them.

**Cold-short**—Signifies a condition in wrought-iron and steel in which it cannot be worked below a dulled heat without risk of fracture.

**Cold Tests**—The testing of specimens of iron and steel while cold by bending and drifting them.

**Collapsing Pressure**—The pressure to which boiler furnaces are subjected, tending to force them inwards and crumple them.

**Conical Mandrel**—An appliance, circular in plan, and a conic frustrum in elevation, around which rings of different sizes are bent and corrected.

**Conical Tubes**—The Galloway tubes used in the furnaces of many steam boilers.

**DABBING ON**—Making a weld by the simple contact of flat faces.

**Die-Forging**—Making forgings by stamping them into matrices or dies of hard metal.

**Dolly**—An appliance held up under a rivet head while the tail is being closed.

**Drawing Down**—The act of reducing portions of forgings by hammer blows.

**Drift**—A tapered tool used for enlarging holes.

**Drilled Holes**—These are used in preference to punched holes in high-class work.

**Drop Forging**—The practice of *die forging* when done under drop hammers.

**Ductility**—The capacity of metals of being extended considerably before fracture occurs.

**ELASTIC LIMIT**—The limit beyond which a body will not return to its original length on removal of stress.

**Elongation**—The amount of extension of a body under stress, generally reckoned at the point of fracture.

**Envelopes**—The forms of the plates required to enclose a body of any shape or dimensions.

**Expanding**—Specifically, enlarging the ends of fire tubes to make them steam tight.

**Extras**—Charges above the usual rates, made when the dimensions or shapes of plates, bars, or sections, involve increased expense in manufacture.

**FAGGOT, or FAGGOTTED SCRAP**—Separate odds and ends of wrought-iron brought to a welding heat and consolidated by hammering.

**Faggotting, or Piling**—Preparing *faggotted scrap*.

**Ferrules**—Rings inserted in the ends of many fire tubes to protect the ends of the tubes from the action of the fire.

**Fibre**—The structure of wrought-iron which is developed during rolling.

**Fire-box**—The furnace of a locomotive or a vertical boiler.

**Flanging**—Producing flanges by bending over the edges of plates.

**Flats**—Bars, the section of which is rectangular but not square.

**Flatters**—A species of hammer struck by a sledge and used to impart a neat finish to plain surfaces.

## DICTIONARY OF SMITHS' WORK

- Flux.**—Powdered sand and borax are fluxes used by smiths when making welds.
- Forge.**—An open fire carried on a low platform, and surmounted by a hood and chimney.
- Forge Tests.**—Rough bending and drifting tests made on specimens at the forge.
- Forging.**—The practice of producing shapes in malleable metal at the anvil.
- Fullers.**—Tools having convex edges, struck by a sledge and used for drawing down.
- Fullering.**—The process of drawing down by a fuller. Also broad finishing following chankling.
- GALLOWAY BOILER.**—A modification of the Lancashire type, having the two flues united in one at the rear, and fitted with Galloway tubes.
- Galloway Tubes.**—Cross water-tubes of conical form.
- Gap Gauge.**—A plate gauge having its edges notched to standard widths for measuring work during forging.
- Gaseous Fuel.**—Used for heating reverberatory and rivet furnaces.
- Girder.**—A beam which occurs in numerous designs.
- Girder Stays.**—The bridge stays that reinforce the top of a locomotive fire-box.
- Glut.**—A strip of square or triangular section used for welds.
- Glut Weld.**—A weld made with a glut strip. It is both a butt and a V-weld.
- Gusset Stay.**—A diagonal boiler-stay made of plate and angle.
- HAMMER.**—A percussive type of tool which includes hand, holding-up, set, and sledge groups.
- Hammerman.**—A smith's striker who wields the sledge.
- Hammer Shaft.**—The handle of a sledge.
- Hardening.**—The result of heating steel and quenching it in liquid suddenly.
- Heat.**—Making a mass of metal hot for the purpose of forging is termed *taking a heat*.
- Heater.**—A white-hot lump of metal placed in contact with plated work at a locality where slight correction is required.
- H-Irons.** *Joint sections.*
- Holding-up Hammer.**—A hammer held under a rivet head while the tail is being closed.
- Hollow Fire.**—A smith's fire banked round to enclose a hollow space clear of fuel.
- Hollow Tools.**—*Swages.*
- Hot Saw.**—A circular saw which cuts red-hot metal.
- Hot Sett.**—A smith's chisel ground with a keen edge to sever hot metal.
- Hydraulic Flanging, and Forging.**—Flanging and forging done on dies actuated by hydraulic presses.
- Hydraulic Test.**—A pressure test for steam boilers.
- INTERNALLY FIRED BOILER.**—A steam boiler having its furnaces enclosed within the shell.
- Iron.**—Used in the form of bars, plates, and rolled sections.
- JOIST SECTIONS.**—Rolled sections in iron and steel of the form of the letter H.
- Jumping-up.**—*Upsetting.*
- Lump Weld.**—A *butt weld*.
- LAMINATION.**—A condition of iron plates the layers of which are imperfectly united.
- Lap Riveting.**—The union of overlapping edges of rivets.
- Lap Weld.**—A weld joint made by the overlapping of edges.
- Letting down.**—Lowering the temperature of steel from the hardening to the tempering heat.
- Levelling Block.**—An iron block or table on which plates are levelled by hammer blows.
- Limiting Dimensions.**—The maximum dimensions in which bars, plates, and rolled sections are manufactured.
- MALLEABLE IRON.**—Wrought iron.
- Mandrel.**—A bar of round or other section around which an eye or ring is bent or corrected.
- Mates.**—The men who work together, as the smith and his striker.
- Monkey.**—A kind of heavy hammer suspended and swung by a rope.
- Multiple Machines.**—Machines which embody provision for punching or for drilling a number of holes simultaneously.
- OLIVER.**—An old-fashioned hammer operated by a treadle and spring pole.
- Overall.**—An aggregate dimension, the sum of a number of smaller ones in series.
- PAN HEAD RIVET.**—One the head of which has the section of a cone frustum.
- Pendulum Hammer.**—A monkey.
- Piling.**—*Bagotting.*
- Planed Edges.**—These are adopted on high-class work to ensure smooth edges and good fitting.
- Plate Furnace.**—A reverberatory furnace.
- Plate Gauge.**—A notched gauge for measuring the thicknesses of plates.
- Plates.**—Rolled material in which the length and width greatly exceed the thickness.
- Plating.**—The working up of plates into girders and boilers.
- Porter Bar.**—An extension on a forging, held in the hands of the smith.
- Punch.**—A tool used for driving a hole through a forging.
- QUENCHING.**—Thrusting heated steel into water or oil to effect hardening or tempering.
- RED HEAT.**—Denotes the colour as seen in a dull light, as the shadow of a force or wall.
- Red-shortness.**—A condition in which iron and steel cannot be worked at a red heat without fracturing.
- Reduction of Area.**—The diminution in cross section which takes place at the point of fracture of a bar subjected to tensile stress.
- Reverberatory Furnace.**—An arched furnace in which work is heated by incandescent gases apart from contact with the fuel.
- Rivet.**—A means of union between two or more pieces, effected by enlargements at both ends of a parallel shank, or pin inserted through a hole.
- Rods.**—Bars of iron or steel of various small sections.
- Rolls.**—Machines used either for bending plates to curves or for flattening them in true planes.
- Rounds.**—Bars of circular cross section.
- SAND.**—Used as a flux in welding wrought-iron.
- Sawing.**—Rolled sections are sawn to lengths with economy of material and time, and the advantage of leaving smooth ends.
- Scale.**—The incrustation that forms in steam boilers.
- Sealing.**—Chipping off boiler scale with a chisel-like sealing hammer.
- Scarf Weld.**—A lap weld in which the edges in contact are sloped or tapered.
- Seam.**—A lap joint, or a flanged seam in a furnace.
- Sealing.**—An intermediate fitting on a boiler shell to receive a fitting or mounting.
- Sections.**—Non-plane forms in which iron and steel are rolled.
- Setts.**—Smith's chisels.
- Sett Hammer.**—A broad hammer which is struck by a sledge.
- Shearing.**—Cutting off iron or steel with a scissor-like action.
- Sheets.**—Manufactured materials of large area, but thinner than plates, or below 1 in. in thickness.
- Ship Plates.**—The commoner kinds of manufactured steel plates.
- Shrinkage.**—Allowance for shrinkage of forgings has to be made in smith's dies.
- Sketch Plates.**—Plates cut to special shapes at the steel works and for which extra prices are charged.
- Sledge.**—A heavy hammer having a long handle to permit of swinging it round in a circle.
- Snap.**—A steel die used for imparting a neat finish to rivet tails.
- Snaphead Rivet.**—One having a head semicircular in section.
- Squares.**—Bars square in cross section.
- Stays.**—Used for stiffening the flat plates of boilers.
- Stay Tube.**—A long tap used for screwing holes in fire-boxes.
- Stay Tubes.**—Smoke tubes which also fulfil the function of stays.
- Steam Hammer.**—Used largely in the heavy work of the smithy.
- Steel.**—Mild steels, or those low in carbon, are used by smiths. They include Open Hearth and Bessemer products. Carbon steels are chiefly used for cutting tools.
- Swage Block.**—A rectangular block containing numerous bottom swages, with holes for bending.
- Swages.**—Tools for imparting shapes to forgings. Called top and bottom tools.
- Swaging.**—Drawing down.
- TEES.**—Rolled sections having the form of a T or an F.
- Telescope Plating.**—Relates to cylindrical boiler-shells the rings of which are conic frusta.
- Tempering.**—Hardening carried to a certain stage only, less than the maximum possible.
- Temper Tests.**—Tests made on hardened materials to ascertain their ductility and strength.
- Templet.**—A strip, plate, or framing used for marking out work from.
- Templet Maker.**—A boilermaker whose duties are restricted to the preparation of templets.
- Thinning.**—Corners of boiler plates are thinned where adjacent plates overlap.
- Tongs.**—Used in various forms at the forge and power hammers.
- Tongue Joint.**—A V-joint made for welding.
- Tube Expander.**—An appliance used for tightening the ends of small tubes in their tube plates.
- Tubing.**—Inserting tubes in boilers.
- Tuyere.**—The opening through which blast is delivered to a forge.
- UNITED INCHES.**—The total section in square inches of a rolled angle, channel, joist, or tee.
- Upending.**—Turning a bar into a position with its axis vertically.
- Upsetting.**—Enlarging a portion of a bar by jumping it endwise.
- VEE WELD.**—A weld joint in the shape of the letter V.
- WASHING-OUT.**—Periodical cleaning of boilers with a jet of water.
- Welding.**—Making joints between heated metals and alloys without any cementing materials or extraneous means of union.
- Wrought Iron.**—A comparatively pure iron prepared by puddling.
- YORKSHIRE IRON.**—The purest brands of wrought iron, prepared in Yorkshire.
- ZEDS.**—Rolled sections having the shape of the letter Z.

# GOOD FOOD-HEALTH'S FIRST LAW

The First Law of Health. Chemical Composition, Classification and Uses of Various Food-stuffs. Advantages of a Mixed Diet. Food Accessories. Meat

Group 25  
HEALTH

4

Continued from  
page 3090

By Dr. A. T. SCHOFIELD

IN entering upon this second division of our section, we leave the high and broad general principles of health which we have hitherto been considering for the smaller and yet more practical matters of eating and drinking and clothing, and propose now to consider the application in detail of the *first law of health—good food*.

**The First Law of Health.** This is a subject near to the heart of every true Englishman, and rightly so; for is it not one, if not the sole, corner-stone of health? The object of all food is to repair the waste of the tissues incessantly going on during life, which, we must ever remember, consists in ceaseless metabolism, or destruction and repair. The food taken is consumed in moving and heating the body, and just as it is important for boilers to burn good coal, so in the human economy is it essential for health to have good food.

This, then, being the great general purpose for which we eat, we may further divide *food-stuffs* into two great classes of flesh-formers and body-warmers. Really, the division should be threefold—*flesh-formers*, or repairers of used-up tissue; *body-warmers*, to be burnt up to heat the body; and *body-workers*, to be consumed in mechanical work.

Broadly speaking, there are four sorts of food-stuffs which fulfil these objects. The flesh-formers are mainly the *meats* and *salts*; the body-warmers are mainly the *fats*; and the body-worker, the *starch* or *sugar*.

If these foods are taken in the right proportions the first law of health is fulfilled, but the proportion is important. If we eat too few flesh-formers and too many body-warmers and workers, we get fat and feeble. If we eat too few body-warmers and workers, and too many flesh-formers, we get lean and lively.

It will be observed that of these four foods, *two*—the meat, or nitrogenous, and the fat—are principally *animal*; *one*—the starch—is mainly vegetable; and *one*—the salt—is *mineral*.

**Chemical Constituents of Food.** Furthermore, inasmuch as the first two—meat and fats—are derived from animals that are vegetable feeders, we may say that *three-fourths* of the food-stuffs are ultimately of *vegetable origin*, and one-fourth only is mineral, and of that a minute quantity suffices. So we sum up by saying all human food is directly or indirectly *vegetable*, save a small amount of minerals in salts and water. Turn now to the chemical composition of these four, and we shall find ourselves confronted by a quartette of letters—C, O, H, N, or *carbon, oxygen, hydrogen, and*

*nitrogen*. Of these the essential body-warmer is the solid carbon or coal, and the essential flesh-former is nitrogen—an inert gas, which nevertheless is an indispensable ingredient in the composition of every living thing on the face of the earth. Let us look at the four for a moment.

**Carbon.** This is the fuel of the body, as it is of all the earth. It is the body-warmer and body-worker. Two of the food-stuffs really depend upon this element—*one* vegetable, the other animal. The one is starch—flour, sugar, etc., which forms so large a proportion of our food, and carries on all the mechanical work of the body by giving out as it is needed the necessary force for this purpose. Fat, butter and cream, the other food, keeps up the heat of the body, and where this is difficult to maintain, as in Arctic regions, during the long winter, such enormous quantities of this food-stuff are consumed as to well-nigh form the whole dietary. Not only so, but being eaten to keep the lamp of life burning, and not for greed, the whole of it is digested, which is a feat so remarkable as to be wholly inexplicable did we not know the extraordinary influence of the mind over the body at times of emergency, making it do well-nigh what it likes. One quarter of the amount of fats in ordinary life would prove far too much for the digestion. The wonder of such a consumption will be better appreciated when the real difficulties in the way of the digestion of fat are understood from the article on digestion in the section on Physiology.

**Oxygen.** This is a gas, as are the other two; our principal food elements consist, therefore, of one solid (carbon) and three gases.

Oxygen is the *breath of life*, and though it enters really into all we eat and drink, we derive our principal supply of it from the air through the lungs, rather than from the food through the stomach.

Consider for the moment these two, which, separately or combined in certain proportions, are the very essence of life foods, and yet, combined in another proportion—CO<sub>2</sub> (carbonic acid gas or carbon dioxide)—form a poison, a destroyer of life, a product of decomposition, breathed out of the lungs at every breath.

**Hydrogen.** This again, though forming a part of starches, sugars, fats, etc., is one constituent of *water* (H<sub>2</sub>O), of which by far the greater part of the body is composed. *Without water* there can be no life; any tissue that dries dies. Hydrogen, therefore (in combination with oxygen), may be taken to represent principally the *fluids of the body*.

**Nitrogen.** This inert gas is *the* essential element in all life. It forms a great part of the body-cells themselves, and even serves as food to repair such waste of these cells as is perpetually going on. Nitrogen is found principally in animal food, whether meat, fish, flesh, or fowl. It also occurs in smaller quantities in grain, corn, beans, peas, etc., and is, too, the great agent in forming flesh.

Speaking generally, then, we may say: Carbon, as fats, butter, etc., is for the *heat of the body*; Oxygen, as air, is for the *breath of the body*; Hydrogen, as water, is for the *liquids of the body*; Nitrogen, as meat, cereals, beans, etc., is for the *repair of the body*.

In addition mineral food is required, such as salt.

The source of our supply of these four elements is full of interest. The oxygen and hydrogen we need not trouble about, as they are supplied to us *ad lib.* in air and water. Nitrogen exists also in enormous quantities in the air; and could we assimilate it—that is, receive, retain, and use it in the body as a gas—the whole food problem for the world, and especially for the poor, would be solved. As it is, we cannot take it raw, but only in expensive compounds or food-stuffs, which are the great expense of our dietaries. If we could use nitrogen from the air, we breathe enough into the lungs in one minute to equal the whole food supply of this element for the day. But we *cannot*, and so we are here absolutely dependent, as we have already shown, upon the vegetable kingdom, which can alone store up nitrogen in the form we can eat it; for not only can we not take it raw as a gas, as we do oxygen, but we cannot even use it from an inorganic compound, such as ammonia ( $\text{NH}_3$ ), as we do hydrogen from water ( $\text{H}_2\text{O}$ ). It must be in an *organic compound*, and we should all perish for want of it were it not for the labours of the vegetable kingdom; for even if we eat animals, they owe their flesh and blood to vegetables, like ourselves. On the silent and incessant labours of this lower world in storing nitrogen for us in a form we can take, the very existence of the animal kingdom depends.

**Vegetable Diet.** The vegetable world, we know, *can* obtain its food from inorganic and simple substances. It draws the nitrogen from the soil, and the *chlorophyll* (green colouring matter in leaves) causes the water it draws up from the roots to unite with the  $\text{CO}_2$  of the air and form starch ( $6\text{CO}_2 + 5\text{H}_2\text{O} \rightarrow \text{C}_6\text{H}_{10}\text{O}_5$ ) (6 molecules of carbonic acid and 5 of water form 1 molecule of starch). Vegetables build up compound organic forms from simple inorganic ones, thus storing up force for animals to unbuild and expand, by adding more (or by combustion), with the formation once more of carbonic acid and water. Hence the vegetable process is called *anabolic*, and the animal *katabolic*, *metabolism*.

The vegetable kingdom is an essential link between the inorganic world and the animal kingdom. Animals must have, as food for producing internal warmth, those compound organic bodies that vegetables now spend

their lives in making, in the same way as the vegetable kingdom laid up long ago stores of coal to provide external warmth for us, by its slow combustion into gas, water, and ash. The fire within and the fire without come from the same source. Animals do not, however, dissipate at once all the energy they get; part is used to build up the still more complex forms of animal proteids; so that when these are eaten (animal diet) they provide a still greater amount of stored-up force. Animal diet, therefore, though expensive, is more stimulating than vegetable.

**Wasted Food Material.** Amongst the dreams of men concerning these subjects, none is so beneficent or far reaching as that which pictures us deriving this great and expensive element nitrogen freely from the air. It is really an exasperating thought to remember that thousands die of starvation, who die actually taking every minute into their bodies (by the lungs) food they have no power to retain. It is worse than men dying from thirst on the ocean. So many wild dreams of past years are to-day the commonplace of science, that he would be both bold and rash who would affirm that nitrogen as food may not yet be supplied without cost, just as hydrogen and oxygen are now.

The other element for which we have to pay is carbon. Unlike nitrogen, it can be consumed in a raw state; for coal has been eaten, diamonds have been crushed and drunk, and lead pencils sucked, but we cannot assimilate carbon well and easily; and practically, as its inorganic compound  $\text{CO}_2$  (carbonic acid gas), is a poison to man, we have to depend for it on the organic compounds of starch and sugar, the results of the labours of the vegetable world. So at present we pay heavily for our carbon and nitrogen, getting our hydrogen and oxygen free.

Before leaving these preliminaries let us make quite clear to our readers the life cycle that we spoke of in the first chapter.

Carbon, oxygen, hydrogen, nitrogen, are the elements of the inorganic compounds *ammonia*, *air*, and *water*, and these are built up by the vegetable world into *starches*, *fats*, and *proteids*; we eat them and build them up further into *flesh* and *blood*. Then by that metabolism, or ceaseless change, of which life consists, they are soon unbuild again right down to *ammonia*, *water*, and *carbonic acid gas*, the compounds of the four elements with which we began.

**The Ideal Diet.** Of these four great food-stuffs man for subsistence requires every 24 hours  $\frac{1}{2}$  lb. proteids, such as meats;  $\frac{1}{2}$  lb. carbohydrates, or starches;  $\frac{1}{4}$  lb. hydrocarbon, or fats;  $\frac{1}{2}$  oz. salt; and 2 quarts of water, besides air. In other words, 1 lb. of dry food daily,  $5\frac{1}{2}$  lb. of water, and  $1\frac{1}{2}$  lb. of oxygen in air.

It must be remembered that most food is more than half water; so that about  $2\frac{1}{2}$  lb. of *ordinary* food makes 1 lb. of *dry* food.

The above diet is roughly represented by  $\frac{1}{2}$  lb. steak, 1 lb. each of bread and potatoes, 2 oz. butter, a little salt, 1 pint of milk, and a quart of water.

**Functions of Food-stuffs.** But fats and starches are formed of carbon, hydrogen, and oxygen, and, as they contain no nitrogen, they are not alone sufficient to sustain life. They differ, too, in their use. The sugars and starches only give out force by the combustion of the carbon in them (with oxygen); they give energy rather than heat, and hence are principally of use for *mechanical work*. The fats and oils burn both the carbon and the hydrogen, and this produces great heat; they are thus used for *warming the body*; but they are harder to digest, the easiest forms being those of cream and butter.

The mineral food is principally used to dissolve the rest. Both salt and water are great solvents of proteids, hence salt is so useful with eggs and meat.

Of the flesh formers, as may be supposed, about *twice as much* is required (in proportion to the body weight) during growth as in adult life.

Excess of starch and fat foods is easily stored up in the body and in the liver; but excess of proteids *cannot* be stored up, and they circulate in the blood and cause many evils.

The amount of body-warmers required decreases slightly from birth to death; that of body-workers varies immensely with the work done. In hard work more than double the ordinary amount is required.

**Sources of Food-stuffs.** Having thus glanced at the composition of food-stuffs, we will consider their variety and their sources.

They fall into two classes—inorganic, or mineral, and organic. To the former belong:

1. **SOLIDS.** *Salts*, principally common salt, also phosphates of lime and iron, and others.

2. **LIQUIDS.** *Water*, absolute amount needed 5½ lb. daily.

3. **GASES.** *Oxygen*, about 7,000 grains, or 1½ lb. daily.

No animal organism can live without water, which is continually changed every day, so that Hoppé Seyler's saying is true that "all organisms live in running water."

Organic foods are subdivided into animal and vegetable, and these both include proteids, or nitrogenous foods, and non-nitrogenous foods.

1. **ANIMAL PROTEIDS**, derived from milk, eggs, meat, fish, fowl, etc.

2. **VEGETABLE PROTEIDS**, first discovered in 1838, derived from all cereals—wheat, barley, oats, rye, maize, etc., and from all legumes, such as peas and beans of all sorts. Pea cheese, as made by the Chinese, is an excellent substitute for meat, while macaroni, vermicelli, etc., made by the Italians, is the strongest vegetable proteid food from cereals.

**Advantage of a Mixed Diet.** Before 1838 it was believed that all nitrogen as food must be derived from meat, and hence vegetables occupied a very secondary place. Since then it has been found that so many sorts of grain produce proteids in such large quantities that it is perfectly possible to keep the body in health on *vegetable food only*. There is, therefore, no ground for the great prejudice that still exists against a vegetable diet in the minds of many Englishmen, and although it is probable

that we were never intended to be exclusively vegetarians, the fact remains that at present we eat too much meat, and the introduction of proper vegetable food into the working homes of England would prove a powerful source of both health and happiness.

**The Source of Proteids.** With regard to proteids, we may remark that nitrogen is always being lost, and an animal without this food must waste, and could only exist at all by feeding on itself. It is found in the *gluten* of wheat, in the *albumen* of eggs, in the *casein* of milk as well as in meat, in the *fibrin* of blood, the *syntonin* of muscle, the *gelatin* of connective tissue, and elsewhere. It is also found in the flesh of all other animals, fish, shell-fish, birds, etc. Proteids (with minerals) can sustain human life alone for a short time, but they are such a wasteful diet that they put a strain on the digestive organs so enormous that they cannot long sustain it. Proteids contain 3½ parts of carbon to 1 of nitrogen, whereas we shall see that the daily waste, and therefore the daily food, requires to be in the proportion of 15 to 1. To get enough carbon, therefore, four times as much meat (and nitrogen) must be consumed as is necessary, enough nitrogen for the daily supply being furnished by 1 lb., whereas it takes 4 lb. to furnish the amount of carbon. When we see that, instead of 4 lb. of meat, ½ lb. of fat or 1 lb. of sugar gives the needed amount of carbon, the advantage of a mixed diet is obvious.

**Carbohydrates or Starch Foods.** Non-nitrogenous foods include (A) Carbohydrates, or starch foods, and (B) Hydrocarbons, or fat foods.

1. **ANIMAL SUGARS**, derived from milk and honey. It is not a little remarkable that milk is practically the only source of animal starch or sugar, this being otherwise almost an exclusive product of the vegetable kingdom.

2. **VEGETABLE STARCHES AND SUGARS.** All grains, beans, and vegetables; various sugars—cane, beet, grape, and malt sugars. Alcohol is also a carbohydrate.

Animals fed on these alone have to consume their own tissues to get the nitrogen required. Dogs fed on sugar and water remain healthy a week, then get ulcers on the eyes—as Hindoos do who live solely on rice—and die in a month.

The essential food of life is, therefore, the *nitrogenous*; the accessory, the *non-nitrogenous*. Referring to these as body-workers, it was long thought by the greatest chemists, such as Liebig, that the body work was really done by the proteids. The proof that it is not is as follows: The *waste product* that is found in the body when proteids are used up (oxydised) is *urea*; while the *waste product* of the combustion of sugars (carbohydrates) is *carbonic acid gas*. Careful experiments were conducted by Pettenkofer and Voit, which succeeded in proving that the amount of urea produced in twenty-four hours did *not* vary in proportion to the amount of work done, but that the amount of carbonic acid always *did*. This showed conclusively that work used up the carbohydrates, and not the proteids.

### The Hydrocarbons or Fat Foods. The Hydrocarbons or Fat foods are:

1. ANIMAL FATS. Butter, dripping, suet, lard, cod-liver oil, cream, etc.
2. VEGETABLE FATS. Olive oil, linseed oil, castor oil, cocoa butter, etc.

Both these and the carbohydrates are composed of carbon, hydrogen and oxygen, but the essential difference between them, to which they owe their different names and properties, is due to the fact that in the latter the hydrogen is just twice as much as the oxygen—that is, *in the proportion to pure water* ( $H_2O$ ), and hence they are called hydrates, and have no free hydrogen left to burn, as in the case of sugar ( $C_6H_{12}O_6$ ) for example.

Hydrocarbons, on the contrary, have a great excess of hydrogen over the carbon, and hence have plenty that is free to burn.  $C_{10}H_{18}O$  is a fat formula, and if we deduct 2 parts of H to form water with the oxygen we still have 16 parts of hydrogen left free to burn, besides 10 of carbon.

Besides the above, there are food accessories and beverages. The former include fruit and condiments.

1. FRUITS. These contain various vegetable acids, such as tartaric in grapes, citric in lemons, malic in apples, oxalic in rhubarb, acetic in vinegar, all of which are good for the blood, and assist to keep it alkaline.

2. CONDIMENTS and spices contain various aromatic bodies, which act as digesters.

Of beverages we shall speak later on, and need not discuss them here.

So far, we have been considering food-stuffs, or food materials and the chemical elements of which they are composed. It is our duty now to look at the Foods themselves, and we shall find it a subject of much interest.

Let us take them in four divisions:

1. ANIMAL FOODS.
2. VEGETABLE FOODS.
3. ACCESSORIES, CONDIMENTS, and SPICES.
4. MANUFACTURED and TINNED GOODS.

Among the animal foods, many of our vegetarian friends will, no doubt, be surprised to see milk, butter, and cheese, which they have long treated as vegetable. We begin with meat.

#### Animal Foods

**Meat.** This averages in composition, three-quarters water, one-fifth proteid or nitrogenous food, and one-twentieth fat. A whole ox is one-third fat, a pig one-half.

Meat compares with bread thus, as regards the food-stuffs it contains (in 100 parts):

| Food-stuffs.     | Meat. | Bread. |
|------------------|-------|--------|
| Proteids .. .. . | 20    | 6      |
| Starches .. .. . | —     | 48     |
| Fats .. .. .     | 5     | 1      |
| Water .. .. .    | 75    | 45     |

Or, roughly speaking, 1 oz. of meat is three-quarters water and one quarter proteid, and bread is half water and half starch. Meat has no starch, and bread very little proteid.

Good meat is firm, elastic, moist (not wet), marbled, bright red flesh (not pink or purple), with the fat firm and a yellowish white. This meat does not shrink much in cooking. The best beef is from oxen five or six years old.

Diseased meat is dark, wet, and tasteless; decomposing meat is pale, flabby, with a bad smell and an alkaline reaction, whereas fresh meat has an acid reaction.

Mutton is the most digestible meat, and the wether mutton is best. Ram mutton is coarse and rank.

Pork is harder to digest, unless pickled. Eginetus, who was a great authority on food in the Middle Ages, says: "Among quadrupeds, swine's flesh is more nourishing than any other, because it is most like human flesh, as those have declared who have tasted human flesh by mistake. That from sheep supplies bad juices, and that from oxen forms melancholic humours."

Meat is subject to anthrax (carbuncle), foot and mouth disease, farcy, and glanders, all of which are transmissible to man. Even in diseased meat, most of the poison is destroyed by thorough cooking, but not necessarily all of it; because, though the bacteria may die, some of the toxins or poisons they make may still be in action.

The only real safeguard is to eat sound meat. Tuberculous meat also should *not* be eaten, though it is still disputed whether consumption can be transmitted from animals to men. Sheep have parasites (1 in. long.) in the liver, called flukes, which are killed by cooking. Beef and mutton are also afflicted with other small parasites. Pork is liable to the measles (*not* the same disease as human measles), the small parasites of which are very numerous. There may be 100,000 in a square inch of muscle.

It is most important, therefore, that the meat eaten should be sound in every way.

**Method of Preservation.** Meat is *preserved by cold*. It is not often frozen now (temperature below 32° F.), but kept 3 degrees above (35° F.), which, while it keeps the meat in perfect condition, does not render it hard and dry like the older method. Beef, mutton and lamb are all thus brought in perfect condition from Australia, New Zealand, and America, in ships fitted up for the purpose. Meat can also be preserved by high seasoning, as in sausages; by drying in strips as is done in South America; by curing, as in the case of pork; by smoking, or, again, it can be salted, or canned.

# SHELL-FISH AND SEA SHELLS

Snails and Slugs. Beautiful Shells. Sea Butterflies. Limpets.  
Cuttlefishes. Squids. The Octopus. Shell Incubators

Group 23  
**NATURAL HISTORY**

22

200106-V  
continued from  
page 3072

By Professor J. R. AINSWORTH DAVIS

WE have now surveyed the various groups of backboned animals, and must next proceed to the consideration of the infinite variety of forms collectively known as back-boneless animals, beginning with the highest of these and concluding with the lowly microscopic creatures popularly termed Animalcules. It will be convenient to start with shell-fish or molluscs (*Mollusca*), which include cuttlefishes, snails and slugs, cockles, oysters, mussels, and others.

**Shell-fish.** Molluscs are soft-bodied creatures, not divided into successive rings or segments provided with limbs (like lobsters, centipedes, insects, etc.), and very commonly protected by a calcareous shell. The under side of the body is thickened into a fleshy "foot," by which locomotion is effected, and there is typically a well-marked head. These features are well seen in 380, which represents the edible or Roman snail (*Helix pomatia*), looked at from above.

The Mollusca are divided into five classes:

1. SNAILS AND SLUGS (*Gastropoda*).
2. CUTTLEFISHES (*Cephalopoda*).
3. TUSK SHELLS (*Scaphopoda*).
4. BIVALVES (*Lamellibranchia*).
5. MALL SHELLS (*Proto-mollusca*).

## Snails and Slugs.

In a typical snail [380] the shell is of spiral form, and the body of the animal can be completely withdrawn into it as a means of defence.

The under side of the foot is a flat sole-like expansion, from which a kind of slime exudes, and by waves of muscular contraction the animal is able to glide along a smooth surface, as everyone must have noticed in our common garden pest. The mouth is provided with a singular rasping organ, by which particles are scraped from the food. It consists of a projection rising up from the floor of the mouth, over which is stretched from front to

back a horny ribbon (*radula*), studded with rows of minute teeth, by which rasping is effected.

A great variety of snails live in the sea or between tide-marks, and most of these breathe by means of a plume-like gill (sometimes by two) contained in a gill cavity placed far forward on the upper side of the body and roofed by a membrane, the mantle, which helps to make the shell. The purified blood flows into a two-chambered heart, which pumps it over the body. Some sea snails are pure vegetarians, while others are predaceous and highly carnivorous. In the former—e.g., common periwinkle (*Littorina littorea*), the opening or mouth of the shell is bounded by a continuous curve, and is said to be entire. But in carnivorous types there is a notch or canal [381, 382, 383] for the lodgment of a tube (*siphon*) by which pure water flows into the gill cavity, the reason being that an active flesh-eater requires more perfect arrangements for breathing than a sluggish vegetarian. Some of the carnivorous types

prey upon other shell-fish, using their rasping organs for boring through the hard covering; a procedure which may be aided by the secretion of acid, for dissolving the calcareous matter.

**Shells.** The shells of sea snails are often of great beauty, and three types from among a bewildering variety have been selected for illustration—namely, a rock

shell (*Murex*) [381], a mitre shell (*Mitra*) [382], and a cowry (*Cypraea*) [383]. A smaller species of the last is used in Africa as a substitute

for money. Large sums have been given by collectors for shells of unusual beauty or rarity, and £50 has been paid for a single specimen of a species of cone shell (*Conus*). The helmet shells (*Cassia*) are made up of differently coloured layers, and have been largely employed for the carving of cameos.

**Sea Butterflies.** A great many sea snails have given up the creeping mode of life and taken to swimming at or near the surface, and this has led to much modification in structure. A comparatively large type of the kind is *carinaria* [384], in which part of the foot is altered into a flattened fin, that moves from side to side and propels the animal as it lies on its back. The shell is reduced to a little cap, by which some of the more delicate organs are protected. Part of the floating population of the sea consists of little sea snails (*Pteropods*) which are still more profoundly modified, and on account of their beauty are popularly called "sea butterflies." They move by flapping a pair of delicate muscular fins, and may either possess a delicate glassy shell, or be entirely devoid of any protective covering [385]. So abundant are these little creatures that they constitute the chief item in the diet of the huge whalebone whales.

The sea slugs are descended from sea snails by reduction or complete loss of the shell, with elongation and flattening of the body [391]. Many of them are of elegant form and beautifully coloured.

Sea snails and their allies are protected in a variety of ways from their enemies. The shell is to be regarded as the primary means of defence, and in average cases the animal can withdraw entirely into this house. In many species a hard plate attached to the upper side of the back end of the foot (*operculum*) serves as a sort of front door. This plate is familiar to caterers of periwinkles, who use it as a purchase for the pin by which the delicate morsel is extracted from its stronghold.

**Limpets.** Taetics of an entirely different kind are resorted to by the sluggish vegetarian limpet (*Patella vulgata*), which abounds on the 'tween-tide rocks all round our coasts. The shell has here lost its original spiral form, and assumed a conical shape [396]. When threatened by the attacks of other animals, or in danger of being washed off the rock by the tide, the limpet holds on firmly by means of its strong oval foot, and pulls

down the shell over its body, being then completely hidden from view. Like some other members of its group, it possesses a strong sense of locality, and selects a particular spot upon which to roost, wandering out from this home for two or three yards to browse on sea-weeds, and returning when threatened by the wash of the tide. In course of time, the action of the foot and edge of the shell wear out a distinct oval "scar," the polished surface of which makes holding on a comparatively easy matter.

An interesting feature is that many of the sea snails are protectively coloured, resembling their surroundings so closely that it is difficult for their enemies to see them, and certain species which live on branching corals of different kind, vary in hue according to the nature of their home. Those which swim at the surface of the sea are transparent, often with a bluish tinge, and are thus rendered very inconspicuous. Many sea slugs, on the other hand, are distinguished by the extreme brightness of their tints, and are exceedingly conspicuous in consequence. This is a case of warning colouration, associated with a disagreeable taste, and it has been found that fishes usually reject them as food. Cone shells can inflict poisonous bites.

**Care of Eggs.** There are often arrangements for the protection of the eggs among sea snails and slugs. Sometimes they are imbedded in a sort of jelly which adheres to the various objects, or in a band of similar substance strengthened perhaps by sand grains, or, still more commonly, they are enclosed in hard protective capsules, as in the purple shell (*Purpura lapillus*) [387] and whelk (*Buccinum undatum*). In a few cases the egg-capsules are sheltered within the parent shell until such time as the eggs hatch out. A very elegant device is seen in the beautiful violet snail (*Ianthina*), which lives in the open sea.

This creature constructs a buoyant raft of hardened slime mixed with air bubbles, and to the under side of this the numerous egg-capsules are attached [386].

From the egg of a sea snail or slug a delicate little transparent larva hatches out [395], which

swims about by means of a kind of flap projecting from the head. Its individual chances of survival are very slender.

**Land Snails.** Land snails have no doubt descended from aquatic ancestors, but have lost their gills and converted the gill chamber into a sort of lung for breathing ordinary air. The Roman snail already figured [380], shows very clearly the "lines of growth" upon the shell, which mark the successive additions made as the inhabitant gradually increased in size. This particular species, not infrequent in south-east England, and common on the Continent, is said to have been introduced into this country for culinary purposes by the Romans. Under the name of "escargot," it figures in French cookery, and eaters of this and other species are not unknown in Britain, partly because there is a popular notion that they are a cure for consumption.

Land snails are very tenacious of life, and, under favourable circumstances, can remain dormant for a very long time, under which conditions the mouth of the shell is closed by a partition of hardened slime. Land slugs have only a small shell or no shell at all [392], and the abundant slime which exudes from their skins prevents them from being dried up. Land snails and slugs usually deposit their eggs in the ground, afterwards covering them with earth. The young resemble their parents from the time of hatching.

Some of the lung-snails have taken to living in fresh water, and when these are kept in an aquarium they may be seen to come up to the surface to get air from time to time. The common pond snail (*Lymnaea stagnalis*) [394] is a familiar form, which may often be seen, shell downwards, crawling along the surface film where air and water meet. Its eggs are deposited on stones or water plants, imbedded in a gelatinous mass.

**Cuttlefishes.** These are highly predaceous marine molluscs in which a part of the foot has wrapped round and closely fused with the head. This region is drawn out into eight

arms and two long tentacles in the cuttlefishes and squids [390], into eight arms only in the poulpe (*Octopus*) [402] and its allies. The inner sides of the arms, and of the swollen ends of the tentacles when these are present, are studded with adhesive suckers which are able to hold firmly to prey. Arms and tentacles alike can be stretched out at will to a relatively considerable distance.

The mouth lies in the centre of the arms and is provided with a powerful parrot-like beak, within which is a rasping organ like that of a snail [389]. A large complex eye is situated on either side of the head, and on the posterior side of the body there is a large gill cavity, containing two plume-like gills. The water entering this cavity makes its way through a slit and passes out again through a tube known as the funnel.

The most expert swimmers in the group are the slender-bodied calamaries or squids [390], which dart backwards through the water with extreme rapidity, by forcible ejection of water from the gill cavity through the funnel. An elongated internal shell or "pen," of horny consistency, keeps the body sufficiently stiff, and thus favours quick progression [388]. A triangular fin on each side helps to balance the animal.

### An Enormous Squid.

Some of the squids attain a gigantic size, and would appear to be partly responsible for the legend of the "great sea serpent." In one authentic case the body was 14 ft. long, the arms 10 ft., and the tentacles 24 ft., and still larger specimens have been recorded.

The common cuttlefish (*Sepia*) is relatively shorter, broader, and flatter than a squid, and the internal shell or "cuttle bone" is a broad oval plate made up of calcareous layers [393]. It is

often to be seen cast up on our shores, and is employed in the preparation of tooth-powder. Scraped cuttle bone, under the name of "pounce," was formerly used to dry writing before blotting paper was invented.

A little relative of the cuttlefish (*Sepioida*) possesses a short, rounded body, and half bristles

itself in sand, patiently looking out for prey [397].

**The Octopus.** Turning now to forms with eight arms but no tentacles, such as the poulpe (*Octopus*), we find a plump, rounded body which has lost its internal shell [402]. Most creatures of the kind lurk in holes on rocky coasts, and use their sucker-bearing arms for

creeping about, though they are also able to swim fairly well. Large individuals are not uncommon on the shores of the Channel Islands, and a realistic account of a combat with one of these is given in Victor Hugo's "Toilers of the Sea."

Some of the eight-armed forms have given up the creeping mode of life, and once more taken to swimming, but in a new fashion. Webs have been developed between the arms [398], the result being an umbrella-shaped expansion which propels the animal by alternately opening and shutting.

#### Methods of Defence.

It might be supposed that the active and predaceous members of the group would need no special means of defence, but, as a matter of fact, they have unrelenting enemies such as sharks and porpoises, and ward off attacks in more than one way. As in chameleons, frogs, and many fishes, there are pigment bodies in the skin, and these are capable of contracting or expanding to bring about colour changes in correspondence with the surroundings. The arrangement is undoubtedly protective, but also serves aggressive purposes.

A sort of bag containing an inky fluid opens into the intestine near its termination, and if the attack of an enemy is pressed home the fluid is ejected into the surrounding water, clouding it for some distance. Under cover of this artificial night the mollusc is often able to make good its escape. The pigment sepia was originally prepared from the ink-bags of cuttlefishes.

The large eggs of cuttlefishes, squids, and poulpes are laid

in firm capsules, which are bound together in grape-like masses [401]. Instances of maternal solicitude for these have been recorded. The young animals, when they hatch out, resemble the adult except in size. The argonaut, or paper nautilus (*Argonauta*), one of the eight-armed species, affords a striking instance of care of eggs. The male is small, shell-less, and insignificant, but the female possesses a beautiful ribbed shell, with a keel-like edge, formed by a secretion that exudes from the greatly broadened ends of two of the arms, and is not comparable to the shell of any other mollusc [399]. It is not only used as a dwelling by the mother argonaut, which grasps its ribbed exterior by her two "shell arms," but also serves as an incubator, within which the eggs pass through their development.

into a series of chambers by curved partitions [400]. The animal lives in the last large chamber, and as it grows, continues to enlarge the mouth of this, adding a new partition at the back from time to time. The older part of the shell is, in fact, converted into a series of gas chambers, which help to buoy the animal up and prevent the large heavy shell from becoming too much of an encumbrance. The device has not proved a great success, for all molluscs with a chambered external shell have long since become extinct, with this one exception. It has four gills.

#### A Living Fossil.

There is one existing member of the cuttlefish class—i.e., the pearly nautilus which differs in many ways from the rest, and may be regarded as the last survivor of a group once dominant, a sort of "living fossil" in fact. The rounded body is covered by an elegant external shell, of regular spiral shape, and a section through this shows that the older part is divided

# MIND & THE FUTURE OF THE RACE

Group 3  
PSYCHOLOGY

The "Beginning" of Mind. The Limits of Education. Natural Selection in the Sphere of Mind. The Future is the Child of the Present

9

Continued from  
page 2506

By Dr. C. W. SALEEBY

UNTIL Herbert Spencer published his "Principles of Psychology," in 1855, it had never occurred to psychologists to consider anything but the adult European mind as they knew it. No one had concerned himself with the savage mind, nor with the mental characters of the lower animals, nor had thought that the mind of a child constitutes an extremely important and interesting object of scientific study. The term *genetic psychology* (from *genesis*, begetting) is often applied to the whole of that branch of psychology which treats of the history and evolution of mind. Its philosophic importance transcends that of any other part of the subject.

**Mind "Began" with Life.** Readers of the chemistry course, where the revelations of radium are dealt with, will remember that there is reason to believe in the spontaneous development or generation of what we are pleased to call living matter from what we are pleased to call dead matter. Modern science denies that there is any such thing as vital force, and believes that life is potential in what our ancestors used to call brute and dead matter. But suppose this be granted, let us see where it leads us.

What do we find if we trace back the history of mind? Notwithstanding the opinion of Descartes, we find evidence of consciousness in the lower animals. When we say "let sleeping dogs lie," we assume that there is a difference between a sleeping and a waking dog. If we pass below the mammals and the birds, we find evidence of consciousness, though of a dull and glimmering kind, in the lower vertebrates, including even the fishes. If we then turn to the invertebrates we find that signs of consciousness are still present. If we pass down as low as the insects, we suddenly come upon a new mental world. In bees and ants and wasps, but much more markedly in the social bees and wasps than in the humble bee and the solitary wasp, we find a wonderful mental development, associated, as we should expect, with the presence of a high proportion of nervous tissue. Even so low down in the evolutionary scale we find abundant signs of mind.

**Mind in Lower Forms of Life.** In the subsequent course on Sociology we must find space, which is not available here, for a discussion of some of the ways in which the mental characters of these insects display themselves—in their division of labour, care of the young, obedience, the keeping of slaves, and so on.

If we pass down lower still we soon lose any such developments as these, but still we find sensation. Now, if sensation be a fact or act of consciousness, we must agree that the realm of

psychology has not yet been traversed. Nor, of course, would it be logical to expect to find any point in the evolution of life above which mind was to be discerned, while below it there was none. If we make a bold step and go right down to the bacteria, there we still find sentience or sensitiveness. If anyone questions this, let him watch a leucocyte under the microscope attacking a noxious microbe. Watch a leucocyte fighting a malaria parasite for half an hour on a warm stage in a drop of blood to which a minute quantity of quinine has been added (so as to give the leucocyte a fair—or unfair—chance), and you will not question the existence of sensation in the lowliest forms of life. Upon this you may agree, though you need not credit the stories of leucocytes who find the duel too much for them and retire, but shortly come back again with a couple of friends.

**Mind in the Individual and in the Race.** If, then, mind in its rudimentary forms be co-extensive with life, and if life be, in a rudimentary form, present or potential in all matter, what is the amazing conclusion to which we are led? This is where the realm of psychology becomes continuous with that of philosophy. Our business here is merely to show the relation between the two studies and the stupendous ultimate significance of psychological assertions which we may sometimes have been inclined to accept without seeing, at first, how far they will lead us.

Everyone who has made any study of biology, or the science of life, is acquainted with what is called the *recapitulation theory*, which asserts that the history of the individual is a shortened and more or less modified recapitulation of the history of the race; or, to use the phrase of Haeckel, that "ontogeny is a recapitulation of phylogeny." In the development of mind in a child, then, we expect to find the appearance and disappearance of characters which are not, properly speaking, human; and this, in point of fact, we do find. Often we address a child as "my little man," and half a century ago children were thought to be little men and women. They were assumed to have the same mental characters as their seniors. If a child showed signs of being cruel, thoughtless, selfish, or careless about cleanliness, these characters were put down to original sin or inherent wickedness, and the child was rebuked and punished. But this was really very uncharitable, and, indeed, our forefathers might have learnt wisdom from the most magnificent words that have ever been written about charity. In the course of an incomparable chapter, St. Paul says: "When I was a child, I spake as a child,

I understood as a child, I thought as a child; but when I became a man I put away childish things."

**The Mind of a Child.** Nowadays we see that a child is by no means a little man. We see that he has his own ways of thinking, understanding, and acting. We see that his selfishness and the like really represent mental and moral stages which are prehuman or subhuman. Regarded in the light of the recapitulation theory, the whole history of the development of a child's mind assumes a new significance. The wisest among us are therefore beginning to modify educational practice. It is being seen that, so far as the moral education is concerned, we must blame the child less and try to understand him more. While we seek to lead forth, or educate, the worthy characters, we must seek, on the other hand, as Tennyson, the poet of evolution, said, to "let the ape and tiger die."

But the present writer never deals with psychology without encountering the temptation to write a little treatise on education; and he must refrain. This at least, however, may be said—that when at last we reach a really rational education, which will provide the fittest environment—mental, moral, and physical for the whole child, it will be upon the truths of psychology alone that our practice will be founded.

There is no room here to enter on a discussion of the moral aspects or faculties of the mind, though their importance, of course, cannot possibly be over-estimated. But, at any rate, space must be found for making one assertion, which is of the utmost importance in regard to the practice of education.

### **Brain Cells cannot be Multiplied.**

In accordance with a great law discovered by Herbert Spencer, a cell which has become so highly developed and differentiated as a nerve cell must necessarily have completely lost any power of division. No nerve cell can divide. The number of nerve cells in the brain of a newborn baby—perhaps about twenty thousand millions—cannot be increased, even to the extent of a single one, by any processes of education. Injury or disease may destroy nerve cells; no power on earth will multiply them.

It follows, therefore, that for any given individual there is an inexorable limit of psychical possibility. No amount of education, not if it were continued for a thousand years, could ever cause an Australian aboriginal, nor the present writer, nor, if one may venture to guess, the present reader, to write a "Hamlet" or a Book of Job. The potency of education is therefore limited by what is given by inheritance. This is by no means to say that any of us makes the most of his inherited possibilities, but it has a most important practical corollary. It implies that, while everyone should certainly be given the chance to avail himself of the highest types of education, yet it should be recognised that there are brains and brains. There are those who are predestined, be they educated never so long and well, never to make anything more

than good farm labourers or the like. You cannot educate or draw out of any brain more than Nature has already put into it. Some day, perhaps, we shall try to adapt our education to possibilities; not, to use a very powerful and perhaps cruel image, casting our pearls before swine.

### **Has the Mind Reached its Limit?**

Since there is a curious delusion by which men think of the mind as synonymous with the intellect, some readers may have been puzzled to know how it is that in the preceding sections we have paid so little attention to the intellect, but have spent much space upon temperament, emotion, and will. This has been done of intent. In the first place, we desire to emphasise the fact that men of intellect—not psychologists—have habitually tended to over-estimate the importance of intellect. This tendency is shared by many women, who greatly admire the intellectual qualities of men. But the most important thing in the world is human nature, which is a very different thing from the human intellect, and in discussing psychology, which might have been called the science of human nature, it has been our purpose to interest the reader, if possible, rather in the fundamental facts of character and in the circumstances that determine action, rather than in questions of thought. Nevertheless, it is no purpose of the present writer to depreciate the intellect, and if it were so, the SELF-EDUCATOR would be a most ill-chosen medium for his purpose. It has, fortunately, been found possible for us to consider the intellectual processes with the measure of attention that they deserve, and the arrangement has one particular advantage. This is, that the reader may perhaps be helped to clearness in his study. Let us think of Psychology as the science of mind or, perhaps better, the science of human nature; and let us think of Logic as the science which concerns itself with the intellect and the intellectual processes. Logic is to be the subject of a succeeding course. But meanwhile, there remains a short space in which we may conclude the course on Psychology by a brief introduction to a question which has long interested the present writer.

**The Future of the Race.** We are all evolutionists nowadays; we "think in evolution"; and we sit no longer with averted gaze upon the unalterable past, but with our eyes upon the course that lies in front of our species and upon the distant goal. It has been admirably said that he who sets forth to discuss the theory of organic evolution but forgets its implications for the future is like a man who sets out to tell a good story but leaves out the point. Now, in preceding pages, we have referred to the development of mind, and it is not our intention to leave out the point.

The future evolution of man is of more interest to the psychologist than to the biologist. What is the meaning of this curious statement? It is that the future physical evolution of man *makes no great promises*. Biologists teach us that the animal race has ever been striving to become

erect, that man has gained the erect attitude, being not only man the erect, but, as Stevenson puts it, "man the erected," that his fore limbs are free for higher purposes than those of locomotion, and that the future course of his physical evolution will tend to consist rather in the disappearance of useless parts—such as toenails—than in the appearance of any new and important characters.

**The Race is to the Wise.** The first reason for this belief is, as we have already stated, that the goal of physical evolution—the attainment of the erect attitude—has been already reached; but there is another reason which is constantly forgotten in the popular notion of organic evolution—the most interesting, important, and misunderstood of all subjects about which anyone can write. The great agent of evolution is natural selection. Characters of body—and this is profoundly true of characters of mind—survive because they are of value in the struggle for existence. Without natural selection, choosing the best—as it usually does—and allowing the worst to die out, there can be no progress. One of the reasons why physical evolution makes few promises is that natural selection on this plane has been profoundly modified by the development of the human mind. The race is not now so much to the strong as to the wise; not so much to the lusty as to the self-controlled; not so much to muscle as to mind; not so much to brawn as to brain. Nowadays, if a man has a good head, he may survive and yield children who tend to inherit his advantage, even though he may be of small stature and a very poor match for a Hackenschmidt.

**The Evolutionist Must Be an Optimist.** Natural selection is now manifested most stringently in the sphere of mind. There is every reason to believe that the stringency of such selection will increase with the centuries. This necessarily means that every mental character which has *survival value* will be accentuated and multiplied. Clear perception, good memory, accurate association of ideas, vivid representation, strong inhibition, rapid and effective action when inhibition is removed, highly-developed but well-controlled emotions, keen but discerning sympathies—all these characters and many more will tend towards higher development. This is the belief of the evolutionist, who, as we have repeatedly maintained, must necessarily be an optimist.

If previous sections of this course have fulfilled their purpose, the reader will approach with a critical mind such an expression of faith as this; he will say, "I know you optimists: you have good digestions and sleep well, and you tinge your philosophy with the fortunate temperament which results from the smoothness of your internal processes."

But though much optimism is a matter of internal sensation—is, indeed, *organic optimism* as we have called it—this admission by no means excludes the possibility of an intellectual or rational optimism. Herbert Spencer and Charles Darwin, the greatest of evolutionists, were

foremost as optimists, yet both of them suffered throughout practically the whole of their lives from nervous indigestion and insomnia.

**The Future will be Greater than the Past.** "What is possible for human nature here and there is possible for human nature at large," says Herbert Spencer. Sometimes, in our admiration for a Beethoven, a Goethe, a Newton, or a St. Francis we are apt to think that we shall not look upon his like again. But every one of such men is a demonstration of the possibilities of human nature, and is thus a certain proof that we *shall* look upon his like again—or better still, not his like, but his peer. The higher the plane upon which natural selection acts, the more rapid and certain will be the mental evolution of man. The higher the mental average of any society, the greater is its chance of producing the greatest men. This has been conclusively proved for us by Greece; it stands to reason; and it is in strict accordance with the laws of heredity discovered by Dr. Francis Galton.

There is one simple and obvious method by which mental evolution might proceed apace. If the father's knowledge were transmitted to his child, or if, even, the father's acquired facilities for attaining knowledge were transmitted to his child, if each generation stepped into at one pace, or rather possessed from the first, the sum of all the mental advance of all previous generations—then mental evolution would be a thing of lightning speed. The reader is, of course, aware that the possibility of the inheritance of acquirements of all kinds has been argued by biologists for decades past, and the verdict is an almost unqualified negative.

**The Inheritance of Acquirements.** Dr. Archdall Reid, who has been quoted elsewhere in this work, has shown that the physical continuance of the race would be impossible if the consequences of every injury, accident, and disease registered themselves in the next generation. From the point of view of the biologist and of the physician, it is a matter for congratulation that acquirements are not transmitted. Indeed, the race could not otherwise persist. But from the point of view of the psychologist, it is a matter of the utmost regret that acquirements are not transmissible. How pleasant for the reader's children if for them the SELF-EDUCATOR could be, so to speak, "taken as read," and they could proceed further, so much work having been done for them by their fathers, and its results transmitted to them by the laws of inheritance. But as everyone knows, this is not so. A man's wisdom dies with him; and the results of education directly concern the individual alone.

To this statement, of course, there is the qualification that, though a man's wisdom does die with him, strictly speaking, yet by means of speech and in infinitely greater degree by means of writing, it can be preserved. Many students have thought that the supreme advantage of man, as compared with the lower animals, is the fact that by such means the knowledge and wisdom of one generation are not lost, but persist.

**Natural Selection in the Highest Sphere.** In this limited sense it is true that we do indeed stand upon our parents' shoulders, and therefore can see further. The future of the race can never be the same as if Kant and Spencer had never lived; though these mighty ones left no children. But this indirect inheritance is a fundamentally different thing from the true inheritance of acquirements, and for its success it depends upon the inherent qualities of each generation. If some cause were to lead to the production of semi-human children, all that the kings of thought have accomplished would be lost in a generation; libraries and pictures and music scores would be burnt for fuel, and barbarism would have been re-established.

It follows, therefore—and this conclusion is of supreme importance—that the progress of humanity essentially depends, as also does even its retention of what it has already gained, upon the continued application of the law of natural selection in the highest sphere of all—the sphere of mind and character.

And here is the danger which many careful observers are coming to recognise. The future is the child of the present. The history of the human race is determined at any moment by the characters of those persons then living who become parents. The race will advance; stupidity and vice and brutality and ugliness of soul—these will disappear *according as the duty of continuing the race is performed by the best rather than the worst at any age and in any place.*

**Society Breaks a Natural Law.** Thus the birth-rate is a subject of the profoundest interest to the psychologist. Profoundly interested as he is in education, and convinced of its potency, he is yet equally convinced of the importance of *heredity* as well as environment or education, in matters of the mind. He realises that human nature is responsible for most of the evil of the world, and when he sees the birth-rate low among the thoughtful, the fine-minded, the sensitive, the sympathetic, and high amongst the brutal, the improvident, the criminal and the unself-controlled—he wonders what the upshot of it all will be. It seems to him that the

beneficent law of natural selection, under which we have progressed thus far, is in danger of being set aside by society, consciously or unconsciously. Meanwhile, he looks with the utmost impatience upon bachelor bishops and others who lament the fall in the birth-rate without for a moment inquiring whether quality is not as important as quantity—and a millionfold more so.

**The Science of Good Breeding.** It is this question of the quality of our children—and pre-eminently, of course, in relation to the intellectual and emotional characters—that has engaged the attention of Dr. Francis Galton, the first student of heredity in psychology. The science or social creed which seeks to establish the encouragement of the parentage of the better and the discouragement of the parentage of the worst, this great student calls *eugenics*—which is literally good breeding.

The present writer, being a eugenicist, is favoured with Dr. Galton's friendship, and has repeatedly written in favour of eugenics. The first appearance of this subject in the reviews is to be found in an article by the present writer, "The Essential Factor of Progress," in the "Monthly Review" for April, 1906. It is his hope that, having been privileged here to address such a magnificent audience as the SELF-EDUCATOR affords upon the science of mind, he may succeed in interesting not a few in that great practical doctrine to which, as it seems to him, all psychology must necessarily lead—the doctrine that mind is still in evolution and that it is our duty and privilege to accelerate as best we may this greatest of all processes. Then will our children indeed rise up and call us blessed.

The science of mind and character is the basis of all the human sciences. The more important of these are separately treated. The reader will follow naturally the rest of the subjects in this group. Immediately following upon this are PSYCHICAL RESEARCH and LOGIC, admirably contrasted as showing the variety of the studies to which Psychology leads. Thereafter the SELF-EDUCATOR deals with SOCIOLOGY—the science of man as *mankind*—and then with PHILOSOPHY and RELIGION, including the principles of morality.

VEHICLE CONSTRUCTION

continued from  
page 3025

By H. J. BUTLER

**H**ITHERTO we have dealt only with the body.

Before the vehicle can be applied to the road an under-carriage or gear has to be made and fitted. Sleighs have merely runners attached to separate the bottom from the frozen road, while sling vans are an instance where the body is transferred from one under-carriage to another.

Although there are still plenty of four and six-wheeled railway vehicles in the United Kingdom, the bogie type will soon be as prevalent here as it is in the United States. Having reached the limit of width in our railway rolling stock without increasing the loading gauge, it is the natural tendency to design long vehicles. These demand special under-carriages capable of negotiating safely and easily the curves of the permanent way.

**Bogies.** The car truck or bogie may be considered as a little wheeled vehicle in itself, through the centre of which runs the pivot or king bolt on which the superimposed body turns. The bogie is also designed with the view of giving increased riding comfort by the arrangement of its springs. Bogies may be four or six-wheeled.

The shocks from the rails and points are transmitted to the wheels and then to the springs immediately supported over, or in some types connected with, the journals. These springs are attached to the bogie frame, on which is mounted a second series of springs. By this means the vibration is well absorbed before it reaches the central turning pin of the bogies, thereby giving a degree of comfort impossible with the directly hung four and six wheeled carriage. The bogie carriage is also a larger, and consequently heavier, vehicle, which means smoother riding.

A similar scheme of isolation of the body from the inequalities of the road is seen in the C and under-spring perch under-carriage of a victoria or brougham, and in the mail under-carriage of a phaeton or drag.

**Bogie Springs.** In rail and tramway work both helical and laminated springs are used. The helical spring is a spiral or coil spring, which in heavy freight car bogies runs up to 1½ in. coil, the internal space inside being about 3 in. Laminated springs, or those made up of leaves or plates, are elliptic in American practices, while here the side or half elliptic is mostly used at present in bogies.

Regarding the distribution of these types, generally speaking the car trucks in the States take the first shock in the helical side springs and transmit them to the elliptical bolster springs. These bolster springs may be double, triple, or any number in side combination up to

six. The English practice is to reverse the placing of the two varieties, and we are familiar with the long side body springs seen under our bogie coaches.

The drawback in laminated springs is the friction set up between the plates. This retards their action to an extent. On the other hand, the helical variety are often too responsive, and mechanisms known as *dampeners* are adopted as reducing agents.

**Bogie Frames.** The use of oak and ash in the construction of bogie frames has been upheld on the argument that this material is a better absorbent of vibration than metal. In American car trucks these woods are largely used, the fact that there is plenty of the timber at hand being no doubt a stimulating influence. But timber, especially in these large pieces, is liable to be unseasoned and faulty; also, steel is much cheaper than formerly, and makes a far stronger and more reliable frame. Bogies may be of wood strengthened with plates, of wood and steel, or of steel only. An English type of the second variety will now be described.

**An English Bogie Frame.** The frame work is of mild steel, the sides (*solebars*) and ends (*headstocks*) both being angular in section. In the centre some 16 in. apart and parallel with the headstocks run the two channel steel cross-bearers. This skeleton is strengthened with four diagonal pieces of angle steel riveted on top, two connecting each crossbearer and headstock.

These cross-bearers perform the important function of carrying the ash spring beam and the superimposed helical bolster springs, above which is the oak bolster itself, with its 2½ in. pin. On this pin the body turns, so we see that the cross-bearers perform a vital function. Perhaps the term *body springs* suggests their importance better than bolster springs. Both the spring beam and bolster are plated on the side. The vertical movement imparted to the bolster by the springs underneath naturally causes friction between the outside of the bolster and the inner surface of the cross-bearers. Wearing plates are therefore fitted. The helical springs are retained in a proper working position by cast-iron blocks bolted above to the bolster and below to the spring beam. Directly to the solebars are swung the side springs, which are attached in the centre over the axle boxes.

It will be noticed that these springs are outside the wheels, an opposite practice to the method usually adopted in road vehicles. Although some London omnibuses were so fitted, their building has now been discontinued.

Into the channel of the cross-bearers is fitted a cast-iron packing block at each end by the solebar, the whole being drilled to take mild steel U-shaped suspension bolts. From these bolts swing the fork hangers, which drop close to the outer edge of the spring beam. Then from the lower end of each pair of hangers are attached the spring beam castings, which pass underneath the beam and are checked in  $\frac{3}{4}$  in. The fork hangers do not hang vertically, but are inclined inwards at the top, so minimising oscillation.

The two sets of three helical springs are arranged in the form of a triangle, the apex of which points towards the inside, one spring being  $\frac{1}{4}$  in. shorter than its fellows, a combination which prevents to a great degree the rolling of the vehicle. Sometimes a helical spring is placed inside a larger one to economise room, but it has the distinct disadvantage of causing a broken spring to remain unnoticed. On the top of the bolster we have at each end the cast-iron side-bearers for the body, and in the centre the pivot with its plate, the bolts which fix it being carried through to retain a plate on the underside of the timber. From  $6\frac{1}{2}$  in. at the sides, the bolster is strengthened to 8 in. in the centre.

Apart from all this, provision has to be made for carrying the brake, and when the position of any members can be designed to take the fittings for the brake without the use of special iron work, the plan is adopted.

**An American Bogie Frame.** A Pullman six-wheeled passenger car truck is made up of two American white oak sides (*wheel pieces*), plated with an inside and outside wheel piece plate. The wheel pieces are joined by the *end pieces*, which we call *headstocks*. In the centre, parallel with the end pieces, we have two wooden outside transoms.

To the top of the spring beams are bolted the centre bearing arch and inverted arch bars. These two bars are together at the transoms, but one arch bar rises while the other falls, so that at the centre they are capable of embracing the centre brace block, which carries the truck centre plate.

From the outside and middle transoms fall the swing fork hangers, at the lower extremity of which is attached the spring plank. Between the spring plank and the spring beam are the four double elliptical bolster springs.

The side helical springs, or equalising springs, are retained in position by the equalising bar, which runs from the tops of the axle boxes, dipping down between each, the springs resting in the middle of each dip. The tops of the equaliser springs are retained under the wheel pieces.

**Difference Between English and American Bogies.** The chief difference between the two trucks is that the four-wheeled English one has the bolster springs and body bearings in the centre between the wheels, in a mild steel frame strengthened with diagonals, while the six-wheeled Pullman, the bearings being also in the centre, has the bolster springs between the centre and side axles mounted in a wooden

plated frame strengthened by longitudinals, and the side body bearings are outside the frame proper while inside in the British design. There are numerous other types of bogies or trucks, but their system and arrangement have the same underlying principles.

**Road Vehicle Under-carriages.** The bogie of a railway coach has no great amount of *locking* or lateral motion when rounding a curve, but a brougham or victoria is often called upon to turn completely round in a street of medium width. This motion is provided for in the presence of the wheel plate (or American *fifth wheel*). The body has to be designed to allow of the free passage of the wheel while turning. In some cases only a partial lock is provided.

**C and Under-spring Perch Suspension.** The perch under-carriage [40] is the better and older form of suspension for road vehicles, but is now comparatively little used. The body is hung at the back and front by four braces, passing round C springs, to which they are attached and regulated by winding jacks. These springs are fixed to the front and hind under-carriages. The two under-carriages are held together by the perch, thus giving more direct draught and preventing the tops of the C springs from being pulled in. Naturally a body hung at each corner on a leather strap tends to sway uncomfortably when on a rough road. To counteract this swaying, check braces are attached to the body from the belly of the perch. Broughams, landaus, victorias, sociables, double victorias, lady's driving phaetons, and all carriages used on special occasions, such as dress coaches, chariots, and landaus [40] are fitted with this suspension. The details of construction, as shown in 40, are as follow:

- |                   |                          |
|-------------------|--------------------------|
| 1. Salisbury boot | 9. Check brace           |
| 2. Body loop      | 10 & 11. Under-spring    |
| 3. Close futchell | 12. Platform             |
| 4. Dumb           | 13. Jack of C spring     |
| 5. Front C spring | 14. Band of C spring     |
| 6. Hind C spring  | 15. Shackles of C spring |
| 7. Standard       | 16. Scroll of C spring   |
| 8. Wood perch     | 17. Platform block.      |

In a perch under-carriage the front wheels in turning can travel only as far as the centre of the body, less half the thickness of the perch. In some cases the perch has been cranked upwards to allow of a free passage, but this entails heavier material and costlier working, and is rarely seen. In the ordinary perch under-carriage a locking stop is provided on the wheel plate to prevent the tyre from striking the side of the perch.

**The Perch Under-carriage.** The several members of a perch under-carriage are shown in 40. Attached to the top of the wheel plate we find the top bed or transom, the middle of which is placed immediately above the turning centre, and therefore usually receives the perch bolt, called, in America, the *king bolt* or *centre pin*. The transom is usually plated on top, the greatest thickness being in the centre, so as to accommodate the head of the perch bolt. Also, on the top of the wheel plate and taking the hind bearing, the horn bar is found. The transom and horn bar receive on their extremities the two front

C springs, to which they are bolted. Flapped on the horn bar and taken through the transom runs the front of the perch, which is smaller at the front than at the back of the wheel plate. A pedestal makes up the thickness in front, where it is bolted to the wheel plate. Often the perch stops at the transom, and a stay is provided from the top of the perch bolt to the front of the wheel plate. Between the perch and spring bearings two nunters are framed through. Immediately under the wheel plate is found, centrally and carrying the lower half of the perch bolt, the axle or bottom bed. It is usually strengthened underneath with a bottom bed plate, thickened in a similar manner to the transom plate and running up to under the spring

carriage beds by being flapped above them. In a closer coupled carriage one may often find the two hind beds equidistant from the axle; when one of the beds is found immediately over the axle it is not unusual to call it the *hind axle bed*.

Nunters are also framed through these beds as they are through the transom and horn bar in the fore-carriage. The hind C springs are similarly fixed, likewise the dumb and under-spring. An important piece of iron work, the hind cross stay, is provided, running from the front of the hind dumbs to the perch.

**The Mail Under-carriage.** Another type of perch carriage is the mail under-carriage [41], used under four-in-hands, brakes, and

40. SIDE VIEW OF A DRESS LANDAU

Showing under-carriage, having a C and under-spring suspension combined with a wooden perch

dumbs. Through the axle bed is framed the close futchells. Immediately under the wheel plate, at the pedestal, we find the front felloe piece, and at the back the hind felloe piece. They are fixed to the futchells below. At the extremities of the bottom bed, a clip is placed over the dumb ends and bolted together on to the top of the dumb with the bottom bed plate, the last mentioned being underneath the dumbs.

The dumbs are solid, imparting no spring motion. They serve to connect the ends of the under-spring, a shackle being provided at the rear to allow of lengthening, under the varying load. A stay usually runs from the ends of the futchells to the top of the dumbs, and is there bolted. On the futchell, sometimes under it in the case of a curved pattern, is fixed the splinter bar, to which the horses are attached. A split stay is generally provided, running from the end of the splinter bar to the top of the dumb. In heavy dress work, two stays will also be found connecting the ends of the transom and horn bar. The under-springs are clipped to the axle flaps. Thus we complete a brief summary of the fore-carriage.

Following the perch, as it leaves the wheel plate, we find it following, to a great extent, the bottom conformation of the body. The perch, when iron, is connected to the two hind

phaetons. The details of construction shown in the illustration are as follow:

- |                       |                          |
|-----------------------|--------------------------|
| 1. Close futchell     | 7. Wood perch (straight) |
| 2. Outrigger futchell | 8. Wing of perch         |
| 3. Cross spring       | 9. Elbow spring          |
| 4. Side spring        | 10. Hind bar             |
| 5. Bedded axle        | 11. Cross spring         |
| 6. Splinter bar       |                          |

The great difference between this mode of suspension and the C and under-spring types lies in the fact that the body is attached directly to the springs. In a drag, these springs, both back and front, are platform springs, a combination of two side and two cross springs. The cross springs are attached to the body, and the side springs to the cross springs by shackles. The latter are clipped to flaps, forged in the solid with the bed plate. In addition to the close futchells, outside or outrigger futchells are provided, which are clipped to the splinter bar in front and to the axle bed at the rear. The axles are wood-bedded, thus forming a bottom bed, while the axle takes the place of the plate. Through the bed, which rests on a half-wheel plate, the perch is framed; its belly follows the downward sweep of the body rockers and rises upwards, aided in its duty of retaining the hind carriage by two side perch-wings, all of which are framed through the hind bedded axle. The

## TRANSIT

wooden perch is always plated, and the wings are sometimes plated. In a mail phaeton we have a similar fore-carriage, but a straight perch, and the hind suspension consists of an elbow and cross spring suspended on a gallows iron, which is flapped on a hind bar beyond the hind axle, into which the perch and wings are framed.

41. HALF PLAN OF A PERCH MAIL UNDER-CARRIAGE SUITABLE FOR A PHAETON

**American Perch Carriages.** In a mail under-carriage the shackles would not be capable of performing their function without a perch. In American buggies, however, we see types of suspension in which, although the connecting member is not absolutely necessary, its presence is most certainly an important factor in keeping the front and hind gears rigid and parallel, and at the same time the pull of the animal is first transmitted to the two axles, which is justly considered an agent in reducing the draught. Elliptic springs may be placed either longitudinally or transversely. Several types of side and cross springs are also mounted in various combinations. The great characteristic of this class of work is the elimination of material to the barest margin of safety. The cost of production is small. The style is suited to roads that are such in name only, yielding to the inequalities of the ground where a stubborn and stronger make would break. Besides, if it does collapse, a whole vehicle can be supplied

Army waggons, timber trolleys, and the like, all four-wheel vans are hung without a perch.

In underworks of this type one usually finds two elliptic springs in the fore-carriage, and also in the hind suspension. The latter part, however, is sometimes fitted with two  $\frac{3}{4}$  in. elliptic springs shackled to a cross spring. Where a

heavy load is supported immediately over the hind axle, as in an omnibus [42] or waggonette, we see the use of a side spring

justified, sometimes in conjunction with a cross spring. Light vans are sometimes hung in the same way as private carriages.

**The Elliptic Spring Under-carriage.** The general arrangement of the members in an elliptic spring carriage [43-47] differ little from the perch variety. The front of the perch is replaced by the framing piece, which, in front of the transom, is termed the tongueing piece. Both the transom and horn bar are bolted above to the bottom boot-framing.

In place of the front and hind stay to the dumbs, we have respectively the wheel iron and its back stay. This, however, is sometimes fitted to the perch carriage. In both types the use of one horse demands open futchells, with an adjustable splinter bar [43], in case the owner should at any time wish to drive a pair.

The hind carriage consists of the two pump-handles, generally of iron, or sometimes wood-cased; these are attached to the body at one

42. GARDEN SEAT OMNIBUS UNDER-CARRIAGE

A. Side View B. Front View with part removed to show hind suspension

almost as cheaply as the repair of a heavier type of under-carriage.

**The Usual Type of Suspension.** No doubt the most familiar type to English eyes is the under-carriage without a perch [42-47]. Broughams, phaetons, and other four-wheeled carriages are hung in this manner in a large majority of cases. Excluding American types,

end and the hind springs at the other. A bar—a hind carriage-bar when the pump handles are placed on it, and a pump-handle bar when framed into wood-cased pump-handles—connects the two springs transversely, although some builders consider the vehicle safe enough without it. A detailed list of the parts of an elliptic spring under-carriage are as follows:

### Trade Vehicle Under-carriages

A four-wheeled  
tradesman's vehicle,

although, in its lighter varieties it follows closely the practice adopted in private work, has many types of suspension special to its class. The most common is the square-framed under-carriage in front, made up longitudinally of four guides, with a transverse front and hind bar.

Attached to this frame we have the wooden sweep-pieces and bottom bolster. To the bottom framing of the van body are bolted the top bolster, and the front and hind attachments to the wheel-plate, which are of many types.

Sometimes pedestals are used. Often a bar or shaped block does the duty. Pedestals are also found in the bottom carriage. The wheel plate is necessarily of a larger diameter and thicker than in private carriages. Under the frame is clipped elliptic springs, but far more frequently we find on the under-side the flaps of the bridge or globe scrolls from which hang the side spring. Likewise, we find side springs predominating in the hind carriage, the scrolls in this case being hung from the summers specially placed to take them. Under the frame over the axle we find another bar, which in heavy vans loaded to the front takes the front check

spring. A hind bar is similarly fitted to the body to take the hind cheek spring when used.

**Two-wheeled Suspension.** Vehicles with two wheels have similar means of suspension, in both trade and private work. The greatest difficulty is the proper balancing of the body. The most common method of hanging is by two side springs, with or without a hind cross-spring. We have also two elliptic springs, used in some cases under carts of various patterns and governess cars. Gigs have special types of hanging devoted to them, as mentioned under the varieties of vehicles. Some two-wheel carts are fitted with a pole, the two horses being attached to a yoke suspended in front of them from their collars, as in a coupe cart. In the old-fashioned currie the yoke rests on the horses' backs.

**Truck Under-carriages.** Among trucks the Slingsby's patent under-carriage deserves mention. It consists of three axles, the central one having attached to it two wheels in the usual manner, while the back and front axles have each one wheel, which is free to slide and revolve along the axle between the bearings. Also, it is so arranged that the two side wheels rest on the floor with only one of the sliding wheels, therefore only three wheels touch the floor at a time. The suspension of perambulators and similar small vehicles is shown in 48 and 49.

**Under-carriage Beds.** Beds or bolsters are usually straight in van and railway work, but the carriage maker in the coachbuilder's shop often compasses them forward in the centre to effect a more compact vehicle. A medium distance is  $3\frac{1}{2}$  in. In this way the axle, and consequently the wheel centres, are  $3\frac{1}{2}$  in. behind the perch bolt and turning centres. A bed so formed, owing to the strains and shocks it has to sustain, must under no circumstances be made of bent timber, as is seen in some cheap Continental vehicles, but must be sawn from best ash, with the grain running as much as possible in the direction of the piece in question.

**Boss and Socket Transom Plates.** Under the transom bed is fixed the socket transom-plate, while on the top of the axle bed is secured the boss plate. The fitting together of these two pieces of ironwork forms a collar that works round the perch bolt [47], and in the unlikely event of a broken perch bolt the arrangement adds to the safety of the vehicle.

**Wheels.** When primitive man wished to move an object along the ground he found that the tree trunks lying around when placed underneath considerably reduced the friction and, therefore, the amount of energy required for removing the article. From the roller the wheel was evolved, and it is very easy to imagine that the first wheels were simply discs. We associate the first wheels with the chariots of old. On the invention of the wheel the whole trade of the building of all types of vehicles has sprung up, and to detailed improvement we owe the presence of cycles and motor-cars of all descriptions.

Wheels in road vehicles transfer the friction set up between the outside of the tyre and the road surface to a generally highly lubricated and specially hardened axle arm and encasing box. It will be seen that the larger the circumference of the wheel, the easier it will surmount obstacles and the fewer revolutions it will make in travelling a given distance, therefore setting up less attrition. Likewise, the smaller the relative size of the axle arm, the less the frictional surface.

However, in most vehicles a large wheel is inconvenient for many practical reasons, and we must not diminish the diameter of the axle arm beyond a certain point in proportion to the load, otherwise the safety of the vehicle and its contents will be endangered.

**Railway Wheels.** In railway work the wheels run on a metal track, and have, except for the breaks between the rail lengths and at the points and crossings, no obstacles to surmount as a road vehicle has. The presence of a track 4 ft. 8½ in. wide has necessitated building over the wheels, so that we see the wheel diameter reduced in many cases to 33 in.

Generally, a steel tyre is bolted to a centre which may be composed of compressed paper, cast-iron (either of disc or spoked form), or of wood. Various methods of fastening the tyre have been invented. Also the whole wheel may be of chilled cast-iron, which forms a type in favour for tramcars.

**Wheels of Road Vehicles.** The wheels of road vehicles consist of an oak stock for heavy work, and elm for light work, mortised to receive the tenons of spokes—in this country of oak, and in America of hickory. The outer ends of the spokes are tanged in pairs into an ash felloe, or into a hickory rim bent by steam.

The whole is protected and strengthened by a steel or iron tyre shrunk on either by natural contraction after heating, or by cold hydraulic pressure.

**Stocks.** After proper seasoning, during which the centre has already been bored out, the sapwood is removed, and the stock turned to the pattern required. After hooping it is ready for mortising. The centre of the spoke must be on the centre of the axle box.

**Spokes.** The number of machine-made spokes greatly exceeds those made by hand. Many will affirm that a hand-made spoke is stronger. Naturally, a machine will get a spoke out of a piece of timber whether it is fitted for it or not, much depending on the forethought and capabilities of the man in charge. The hand-made spoke is cleft from pieces of oak a little larger than the finished size. Placing the sapwood to the front, they are planed up true, and the face squared, care being taken that the foot is in an exact line with the body of the spoke. After the spokes are fitted to the stock, the wheel or *speech*, as it is called, is now ready to receive the felloes.

**Felloes and Tyres.** The felloes are fitted so that, although meeting on the inside, they are open about  $\frac{1}{4}$  in. on the outside. Also, they are got out to a shape that is a little higher than the given diameter of the wheel. Generally, the

proportions are 3 ft.  $\frac{1}{4}$  in. for a wheel given as 3 ft., and so on, allowing about  $\frac{1}{16}$  in. for every foot of wheel diameter.

In fitting the spoke into the felloe the tangues are split and wedged with a piece of oak, usually a spoke cutting. Dowels are also made of the same material. The tyre is shut up a little shorter than the circumference of the felloes, the actual measurement depending on the nature of the material used, its thickness, and the type of wheel about to be shod.

#### Dished Wheels.

The most casual observer will notice that wooden wheels are dished—that is, the distance over the top of the wheel is greater than a corresponding measurement taken on the road. It is said that a wheel so formed looks better, is stronger, but what is more important, causes the wheel to wear against the axle collar rather than the outside collet or nut, a state of affairs which is obviously safer. The practice of lessening the dish of wheels in private carriages is to be commended, for its exaggeration certainly detracts from the beauty of an otherwise well-designed carriage. Artillery wheels have the foot of the spokes cut so as to form a perfect arch resting round the axle box, completely filling the space between the latter and the bolts of the hub flange. We should include castors with wheels, as they are adapted to many forms of trucks.

**Brakes.** The first idea of a brake was to retard the motion of a vehicle when descending an incline, and in road conveyances this is its chief use. But on the railway the powerful types used are to bring the train to a standstill not only at the station platform, but also when a signal may be at danger. Road-vehicle brakes are also fitted, so that progress may be checked as the exigencies of the traffic demand, and any case of emergency that may arise from pedestrians or otherwise.

The chief types of brakes used on railways are the vacuum and the Westinghouse. It must be at once admitted that a certain amount of controversy exists as to which is the better. Both are described, and the reader may judge upon which side superior merit lies.

**The Vacuum Brake.** In the vacuum automatic brake the power is applied by admission of air to the apparatus, while it is

released by the creation of a vacuum. To quote from the company's handbook, "The brake can be applied by the guard, and is self-acting in the case of an accidental parting of the train, or any damage happening to the brake itself. It is instantaneous in its action, and can be regulated to a nicety for easy stops, or to control the train on an incline."

48-49. SUSPENSION OF BABY CARRIAGES

**The Westinghouse.** The Westinghouse brake is applied by the application of compressed air, and released by the reducing of that pressure, and, as in the vacuum brake, an accidental fracture applies the brake blocks to the tyres.

The difference between the two types lies in the fact that the vacuum depends on the comparative absence of air (an absolute vacuum being impossible) for releasing the brakes, while the largely-used American type requires merely a reduction in the air pressure to effect the same object.

**Working of the Vacuum.** In the Vacuum brake the brake blocks are connected by levers which are moved by a piston working in a cylinder. The pressure is applied by admitting air into the bottom of the cylinder below the piston, which

in rising, applies the blocks to the tyres.

The brake is released by exhausting the air below the piston by the admission of steam to a small ejector under the engine-driver's control. The braking power may be destroyed more promptly by using a larger ejector, which is also fitted in the engine. These two ejectors are known together as the combination ejector, the smaller being placed inside the other. The former is worked continuously to maintain the vacuum necessary while the train is running.

**Working of Westinghouse Brake.** In the Westinghouse brake a double-acting air pump is necessary on the engine. It consists of a steam cylinder on top, and an air cylinder below. By means of valves and pistons the steam pressure drawn from the locomotive stores up compressed air in a main reservoir situated under the footplate, which is connected to the air cylinder by a delivery pipe. From the top of the reservoir runs another pipe, to which is attached the driver's brake valve, which is also connected with the main brake pipe running the whole length of the train. This pipe is capable

of being detached at each end of each carriage or car, and control is also placed in the guard's van.

In the latest types of Westinghouse pumps, a steam pressure of 140 lb. will fill the main reservoir of 10 cubic ft. with air compressed to 95 lb. per square inch in 100 seconds. The connections between the carriages consist of flexible rubber hose attached by couplings. When not in use a dummy coupler may be attached to the free end of the hose to exclude dust and grit.

The actual braking apparatus consists of a brake cylinder and piston as in the vacuum type, but an auxiliary reservoir supplied with air from the main reservoir is also part of each vehicle equipment. A triple valve admits air from the auxiliary reservoir to the brake cylinder when the pressure in the main or train pipe is reduced by the driver allowing it to escape at his brake valve, and when the brake is released by increasing the pressure the air escapes from the cylinder into the air, and the train pipe again fills the auxiliary cylinder. The piston rods, as in the vacuum brake, are connected with the brake blocks, and both brakes may be applied gradually or suddenly.

**Relative Use of Brakes.** The vacuum brake does more mileage and records fewer faults per mile than the Westinghouse in the United Kingdom. Both the Great Western and London and North-Western are fitted with the vacuum, while the London, Brighton, and South Coast and the South-Eastern and Chatham use the other. Some railways have part of their stock fitted to take both systems. The Westinghouse is an older invention, and finds almost universal favour in the land of its birth—the United States.

**Road Vehicle Brakes.** No doubt the first brake application was by tying up the wheel; after that came the skid under the wheel, and from then friction has been set up in various forms between the tyre and a block. Sometimes the rim or hub is utilised for this purpose.

**The Bowden Brake.** Among modern brakes the Bowden wire principle as applied to cycles and lately to carriages, is simple, neat, and powerful. It consists of an inner strand of inextensible wire, over this being a tube of closely-coiled wire incapable of compression lengthwise, while outside both is a protecting jacket to prevent mud or other matter from affecting the tube coil. The action consists of the pull of one wire and the resistance of the other, and the power can be transmitted up

and down any path curved or straight between the brake handle and the point of application. In a gentleman's carriage the attachment of a wire cable instead of the usual ugly and cumbersome levers and connecting rods is a distinct factor in enhancing the appearance of the vehicle. Likewise, the cyclist finds he has a featherweight brake.

A brake applied to the rear wheels of cycles does not interfere with the steering, and when applied to the rim, saves the tyre. For many reasons a hard steel wheel rim is a better point of application than is the surface of a tubular indiarubber tyre.

**Band Brakes.** The motor is an instance where band brakes are largely adopted. They are fitted to the countershaft and the hind driving wheels, in the latter instance being often water-cooled. The power is applied by hand levers or foot pedals attached to rods and cables. As in cycles, the pneumatic tyre precludes any direct application to the tyre. Solid rubber and iron tyres, however, allow of the use of spoon and block brakes and less strain is thrown on the wheel.

The application of the countershaft brake usually takes out the clutch, thus disconnecting the engine. Should the brake fail on an incline, a sprag is fitted to drop down and check the car from running backwards, or a ratchet is made to engage in a ratchet-wheel on the countershaft.

**Lever Brakes.** The remaining brakes are those that depend on the power transmitted from a lever. Sometimes we have a single hand lever connected direct to the rolling bar which actuates the brake arms, or we may have an intermediate connecting rod. The power may also be applied by a foot treadle or by a hand wheel. The connecting rod is often swept to conform to the shape of the vehicle. A brake lever rack is for maintaining the pressure when applied. The lever may simply be pushed sideways out of its resting place in the rack teeth, or be released by a trigger, a practice favoured in motor engineering. A treadle may give a vertical pull or a horizontal-pull or push, also a screw brake may work vertically or horizontally. Brake blocks and pans are of many designs. In a perch under-carriage the brake work must be fixed to it and not to the body. Here the Worger-Bowden brake has a decided advantage over the older types. Van brakes are usually powerful types of the lever brakes mentioned. Trams use magnetic brakes as well as other varieties.

Continued from  
page 2063

By J. A. HAMMERTON

**Samuel Richardson.** The "literature of the drawing-room," which Lyly began, was humanised by SAMUEL RICHARDSON (b. 1689; d. 1761), who may be called the father of the domestic novel. As a lad he was the confidant of the young women in the neighbourhood of his home in Derbyshire, the whereabouts of which, for some obscure reason, he successfully concealed. He read and wrote their love-letters for them, which accounts in some measure for his extraordinary success as a writer, chiefly for women, in the later years of his life. At the age of two score and ten, when he was a printer in Salisbury Court, Fleet Street, and possibly, it is suggested, after he had read Marivaux's "Vic de Marianne," as translated and continued by Mme. Riccoboni (1736), Richardson—who knew no language but English—was induced by two bookseller friends to take up the task of writing a book of "Familiar Letters on the Useful Concerns in Common Life." He was doubtless engaged in this work when he became acquainted with the story which inspired his first novel, "Pamela; or Virtue Rewarded" (1740), although the latter was published several months before the "Familiar Letters." "Clarissa Harlowe" followed, in 1748; and "Sir Charles Grandison," in 1753. These three works form, as Professor Raleigh has remarked, a kind of trilogy, dealing respectively with humble, middle-class, and high life. Professor Raleigh has a capital chapter on Richardson; but the student should not omit to read Mr. Austin Dobson's monograph in the "English Men of Letters" series. One of the most remarkable things in connection with Richardson's work is the deep and abiding interest it has aroused in France.

**Richardson's Characteristics.** His adoption of the epistolary style was at once condemned by Fielding; but, though Fielding's protest was well grounded, the method had its advantages, and is sometimes adopted even now. Perhaps the greatest obstacle in the way of a popular appreciation of Richardson to-day is his prolixity; and another drawback is his passion for moralising. Still, as Mr. Dobson says, he "must always find readers with the students of literature. He was the pioneer of a new movement; the first certificated practitioner of sentiment; the English Columbus of the analytical novel of ordinary life. Before him, no one had essayed in this field to describe the birth and growth of a new impression, to show the ebb and flow of emotion in a mind distraught, to follow the progress of a passion, to dive so deeply into the human heart as to leave—in Scott's expressive words—'neither head, bay, nor inlet behind him until he had

traced its soundings, and laid it down in his chart, with all its minute sinuosities, its depths and shallows.' Added to this there was something in his nervous, high-strung constitution—a feminine streak, as it were—which made him an unrivalled anatomist of female character."

**Must We Read Richardson?** To be perfectly frank we find ourselves unable to urge Richardson upon the general reader. The abnormal length of his novels, their sluggish movement, their lack of real dramatic action, their mawkish sentimentality—these are defects enough to encourage the dust upon them. Let anyone who has not yet attempted to follow the adventures of "Pamela," one of the least attractive females in the whole realm of fiction, or the "impossible" story of "Clarissa Harlowe," or the soporific and interminable history of "Sir Charles Grandison"—let anyone do so, the attempt may at least be made—and none will blame him if he concludes that Richardson is not his favourite romancer. For the student of eighteenth century life, however, the novels of Richardson contain much that is invaluable, as the little printer could certainly observe and portray character as he saw it. Indeed, the fact that he could have won with these three books such immense popularity as he enjoyed in his own day is of itself a valuable index to the mind of his age. We live in brisker times, and are happily less sentimental in the twentieth century. Compare modern character as a whole with that illustrated by Richardson, and it will be found that the change is all for the better. Mr. Andrew Lang could not read "Rob Roy" until he was forty. The present writer read "Pamela" when he was nearer fourteen—chiefly because his mother prohibited the book—and it would have been no deplorable thing had he postponed its reading until after forty, or even until four score years! This touch of purely personal opinion at the present point is thought desirable, since it is unwise to dogmatise over Richardson, and the taste of each reader must decide the matter for himself.

**Henry Fielding.** Richardson's relations to his great contemporaries are thus happily and humorously indicated by Mr. Andrew Lang: "Richardson was a woman's novelist, as Fielding was a man's. I sometimes think of Dr. Johnson's saying, 'Claret for boys, port for men,' and smiling, 'brandy for heroes.' So one might fancy him saying, 'Richardson for women, Fielding for men, Smollett for ruffians,' though some of the latter writer's rough customers were heroes, too."

Two years after "Pamela" was issued there appeared "The History of the Adventures of

Joseph Andrews and his Friend Abraham Adams, Written in Imitation of the Manner of Cervantes, Author of 'Don Quixote.' In this work HENRY FIELDING (b. 1707; d. 1754), barrister, journalist, and playwright, essayed a satire and achieved a masterpiece, just as Cervantes himself had done. The Parson Adams of the story takes rank in the gallery of the heroes of English fiction with Goldsmith's Dr. Primrose—just as Sophie Western sits with the daughter of the Vicar of Wakefield. "The History of Tom Jones, a Foundling," appeared in 1749; "Amelia" in 1751. The "History of the Late Mr. Jonathan Wild the Great," was published among his "Miscellanies," in 1743. Thackeray, whose outlook on the world was similar to Fielding's, has said of him: "He may have low tastes, but not a mean mind; he admires with all his heart good and virtuous men, stoops to no flattery, bears no rancour, disdains all disloyal arts, does his public duty uprightly, is fondly loved by his family, and dies at his work." Thackeray's appreciation is a good antidote to much of the depreciatory criticism that has been passed upon Fielding the man.

**The Place of Fielding.** As a literary artist, if not as a reader of the human heart, Fielding has a place above Richardson, and Sir Walter Scott styled him the "Father of the English Novel." He is a humorist, which Richardson is not. His knowledge of life is wide, his sympathies are catholic, his humour is of the rarest vintage, his style is like the vigour of a spring morning, and his constructive faculty is classical. "There could," says Professor Raleigh, "be no better school for a novelist than is afforded by the study of Fielding's plots." Those who have read their Gibbon will not need to be reminded of the following tribute of the historian to the novelist: "The nobility of the Spensers has been illustrated and enriched by the trophies of Marlborough, but I exhort them to consider the 'Fairy Queene,' the most precious jewel in their coronet. Our immortal Fielding was of the younger branch of the Earls of Denbigh, who drew their origin from the Counts of Habsburgh, the lineal descendants of Eltrico, in the seventh century Duke of Alsace. Far different have been the fortunes of the English and German divisions of the family of Habsburgh; the former, the knights and sheriffs of Leicestershire, have slowly risen to the dignity of a peerage; the latter, the Emperors of Germany and the Kings of Spain, have threatened the liberties of the Old and invaded the treasures of the New World. The successors of Charles V. may disdain their brethren in England, but the romance of 'Tom Jones,' that exquisite picture of humour and manners, will outlive the Palace of the Escorial and the Imperial Eagle of Austria."

That is eloquent praise and not exaggerated. Fielding is securely a classic; his novels are as charged with life to-day as when they first won the admiration of his contemporaries. Dr. Johnson considered "Tom Jones" vicious, though he was fascinated by "Amelia"; but

if the former great novel is too indulgent to the frailties of man, it is an open question whether it may not be so and yet remain a work of sounder morality—certainly far less nauseating—than Richardson's "Pamela," in which we are supposed to witness "virtue rewarded," but a brand of "virtue" that will not bear analysis. Fielding has created a crowded gallery of memorable characters—the true test of the novelist—and student and general reader alike must read him, though neither will need compulsion to the task.

**Sterne.** In addition to Fielding, three other novelists are included among Thackeray's representative humorists of the eighteenth century. In the case of LAURENCE STERNE (b. 1713; d. 1768), however, a distinction is made with which most modern readers will agree. The distinction is that Sterne is a great jester rather than a great humorist. "He fatigues me with his perpetual disquiet and his uneasy appeals to my risible or sentimental faculties. He is always looking in my face, watching his effect, uncertain whether I think him an impostor or not; posture-making, coaxing, and imploring me." The author of "The Life and Opinions of Tristram Shandy, Gent." (1759-1767), and "A Sentimental Journey through France and Italy" (1765) owed much, doubtless, to an acquaintance with the works of Rabelais and Cervantes and Burton's "Anatomy of Melancholy" (1621); but, as Mr. Birrell has said, "Sterne is our best example of the plagiarist whom none dare make ashamed." Careless, usually, of his grammar, he can on occasion find the "only word." He is ribald, but not salacious. As a sentimentalist, he may be—he is—tedious and tiresome. His morals may be bad, but one doubts with Coleridge if they can do much harm to anyone who was not bad enough before. At the lowest estimate, Sterne is a great master of the art of telling a story in an interesting way.

**Smollett.** "The Hogarth of English Letters" is a phrase applied to TOBIAS SMOLLETT (b. 1721; d. 1771). Like Fielding, Smollett commands respect because he was a hard worker. He had "the very deuce" of a temper, maybe; but he sustained many hard, unkindly blows of ill-fortune. He was a stout and manly-hearted Scotsman. Professor Masson includes "The Adventures of Roderick Random" (1748), "The Adventures of Peregrine Pickle" (1751), and "The Expedition of Humphrey Clinker" (1771), with "Joseph Andrews" and "Tom Jones," as "novels as nearly as amusing as any we have" (1859). In them, he says, "for the first time British literature possessed compositions making any approach, in breadth, bustle, and variety of interest to that form of literature, always theoretically possible, and of which other countries had already had specimens in 'Don Quixote,' and 'Gil Blas'—the comic prose epic of contemporary life." In the novels of Fielding and Smollett is represented the kaleidoscope of life; whereas Richardson keeps the attention more intimate with the feelings of his chief characters. One of Smollett's assets is his

## EARLY WRITERS OF ENGLISH PROSE FICTION

Scotticism; and though "Roderick Random" and "Peregrine Pickle" should cease to be read, Scotsmen, in the opinion of Professor Masson, "would still have an interest in preserving 'Humphrey Clinker.'" Like Fielding and Sterne, Smollett was a creator of types; but his own life affords a singular contrast to that led by some of his literary creations.

**Goldsmith.** Of OLIVER GOLDSMITH (b. 1728; d. 1774) it has been said that *Virginibus puerisque* might have been his appropriate and uncontented motto. His one novel, "The Vicar of Wakefield," written though it was with a moral motive akin to that which induced Richardson to write "Pamela," is a work that stands alone. "There are a hundred faults in the thing," says the author in his preface; but as it has been wittily observed, a hundred things might plausibly be said to prove them beauties. The "charming prose idyll of dear Irish Goldy" may be described as both highly improbable and as intimately true to nature.

Written in 1761, "The Vicar of Wakefield" was not published till 1766. Professor Raleigh,

who cites its admirable comedy as perhaps its highest merit, makes a very striking comment in his reference to this work: "The story of its discovery by Johnson, as told in Boswell, is one of the best known and most characteristic passages of Goldsmith's life. The picture of Goldsmith, arrested for debt, changing the guinea sent him by his friend for a bottle of Madeira, helpless and angry, while a completed novel, which sold at the first offer for sixty pounds, lay written in his desk, has often been employed to illustrate the improvidence of authors. It might be better used to illustrate the prudence of an author who was an improvident man. No one ever drew a firmer line between the works he wrote to last and the compilations that his necessities extorted from him than was consistently drawn throughout his life by Oliver Goldsmith. It did not occur to him to expect fame from his histories, political or natural. . . . As little did it occur to him to treat his carefully wrought original works as so much merchandise, or a sop for the bailiff, and perhaps Johnson's kindly offices prevented 'The Vicar of Wakefield'

from receiving its full share of the correction and polish that Goldsmith bestowed on all his best work."

### Minor Novels before "Waverley."

Among the other novels which preceded "Waverley" (1814) must be named "The Adventures of David Simple," by SARAH FIELDING (b. 1710; d. 1768), the sister of the author of "Tom Jones"; "The Female Quixote" of CHARLOTTE LENNOX (b. 1720; d. 1804); "The History of Rasselas, Prince of Abyssinia," which JOHNSON wrote in 1759, partly to pay for his mother's funeral and partly in answer to the witty libertinism of Voltaire's "Candide"; the "Arundel" and "Henry" of RICHARD CUMBERLAND (b. 1732; d. 1811), an imitator of Fielding; "Chrysal; or, the Adventures of a Guinea" by CHARLES JOHNSTONE (b. 1719?; d. 1800?), whose vein was chiefly satirical, and whose quarry was political and domestic vice; "The Man of Feeling" and "Julia de Roubigné" by HENRY MACKENZIE (b. 1745; d. 1831), a follower of the sentimental methods of Sterne; "The Castle of Otranto," a "Gothic Romance," by HORACE WALPOLE (b. 1717; d. 1797), who, as Professor Masson says, did something to remind British readers that "there had been a time in the world when men lived in castles, believed in the devil, and did not take snuff or wear powdered wigs"; "The Old English Baron" of CLARA REEVE (b. 1729; d. 1807), whose crude style succeeded where that of Walpole failed; "The Romance of the Forest," "The Mysteries of Udolpho," and "The Italian" of ANN RADCLIFFE (b. 1729; d. 1807), the originator of the mysterious and fascinating blackguard in fiction—a truly Protean creation; "Hermesprong; or, the Man as He is Not" by ROBERT BAGE (b. 1728; d. 1801); "The Monk" of MATTHEW GREGORY LEWIS (b. 1773; d. 1819); the "Zeluco," of DR. JOHN MOORE (b. 1729; d. 1802); the "Vathek" of WILLIAM BECKFORD (b. 1759; d. 1844); the "Caleb Williams" and "Fleetwood" of WILLIAM GODWIN (b. 1756; d. 1836), one of the first of English writers to utilise the novel for political purposes; "A Simple Story" and "Nature and Art" by MRS. INCHBALD (b. 1753; d. 1821); the "Old Manor House" of CHARLOTTE SMITH (b. 1749; d. 1806); "The Fatal Revenge" and "Melmoth the Wanderer," by CHARLES ROBERT MATURIN (b. 1782; d. 1824), who possessed an almost uncanny power over the treatment of the supernatural; "Adeline Mowbray," by MRS. OPIE (b. 1769; d. 1853); the "Children of the Abbey" of REGINA MARIA ROCHE (b. 1764?; d. 1845); and last, but not least, the "Rosamund Gray" of CHARLES LAMB (b. 1775; d. 1834).

There is scarcely a novel we have named that is not worthy of the attention of the student, not always for its own sake but as a contribution to English fiction before the dawn of "Waverley." The general reader may be left to acquaint himself as his fancy leads and opportunity allows with some of the works included in this list.

**Four Great Women Novelists.** Before "Waverley" was published, four lady novelists had written works which attained a higher level as novels than perhaps any named in the above group.

FANNY BURNLEY, MADAME D'ARBLAY (b. 1752; d. 1840), in "Evelina" and "Cecilia," had treated character with all the realism of Ben Jonson without the coarseness of that writer's dramatic "humours." To quote Mr. Austin Dobson, "'Evelina' marks a definite deviation in the progress of the national fiction. Leaving Fielding's breezy and bustling highway, leaving the analytic hothouse of Richardson, it carries the novel of manners into domestic life, and prepares the way for Miss Edgeworth and the exquisite parlour pieces of Miss Austen."

MARIA EDGEWORTH (b. 1767; d. 1849), whose delightful character finds eloquent expression in "Castle Rackrent." Her work applied a needed corrective to the passion for the weird and horrible romances which Mrs. Radcliffe, "Monk" Lewis, and others had made so popular, but which was to be aroused again in 1817 by the "Frankenstein" of Mary Shelley. Miss Edgeworth's Irish tales inspired the patriotic novels of Sir Walter Scott.

JANE AUSTEN (b. 1775; d. 1817) wrote six novels—"Sense and Sensibility" (1811), "Pride and Prejudice" (1812), "Mansfield Park" (1814), "Emma" (1816), "Northanger Abbey" (1818), and "Persuasion" (1818)—all of which, together with Fanny Burney's "Evelina" and "Cecilia," are frequently reprinted to-day. Macaulay suggested, Professor Goldwin Smith has adopted, and Professor Raleigh looks favourably upon, a comparison between Jane Austen and Shakespeare. This is derived partly from the absolutely impersonal character of her works. She tells us nothing about herself, and she is oblivious of the happenings in the great world beyond her own circle. She is a satirist minus indignation; hers is the quiet irony of the cultured mind; her subtle humour is only audible to the cultured ear. To study her books is to be given a series of invaluable lessons in the art of observation and in precision of detail. Miss Austen's method was appreciated by Scott. "The big bow-wow strain I can do myself, like any now going," said Sir Walter; "but the exquisite touch which renders ordinary commonplace things and characters interesting from the truth of the description and the sentiment is denied me." Miss Austen supplies a faithful picture of the English country life of her period. She gives us, as Mr. Dawson says, "the sort of details about the lives of average people which the historian omits and the sociologist demands."

JANE PORTER (b. 1776; d. 1850) wrote two novels that still retain a certain measure of popularity, "Thaddeus of Warsaw" (1803) and "The Scottish Chiefs" (1810). Both are eminently readable; and they entered a field which so far had been untrodden—the field of historical romance, the chief glories of which were soon to fall to Sir Walter Scott.

page 3069

By JOSEPH W. HORNER

**Cottars.** A cottar is a tapered bar or wedge used for connecting ends of rods into sockets, or as a means of setting up bearing brasses, etc., to compensate for wear.

Fig. 45 shows a cottared joint in a rod, the width of the cottar is usually one and a quarter times the diameter of the rod, whilst the thickness is one quarter of the diameter; the taper of the cottar varies from 1 in 15 to 1 in 30. Fig. 46 illustrates a cottar applied to a connecting rod end where it is used for the purpose of adjusting the brass. The piece lettered G is termed a gib, and forms a guide or backing for the cottar. When it is necessary to make considerable allowance for the setting up of a brass, the taper of the cottar may be increased to as much as 1 in 6; but means must then be provided to prevent it from slipping back. Fig. 47 shows a common device adopted to achieve this object—the head of the gib is extended in circular form, and is screwed and fitted with nuts, the head of the cottar having a head forged on which is drilled to accommodate the screw. Further examples will be given when the design of connecting rods is discussed.

**Shafts.** Shafts are generally cylindrical pieces of rolled or forged steel, but they are sometimes made of square section for special purposes. Ordinary shafting is used for simply transmitting power, and is chiefly subject to twisting forces, the bending actions due to the pull of the driving belts being comparatively small. Engine crank - shafts and the shafts of hauling and hoisting machinery are subject to combined twisting and bending forces, and must be calculated accordingly. The axles of locomotives, railway

carriages and trucks, motor-cars, etc., are subject to bending forces only except in the case of the axle or axles which are driven; they must be then calculated to withstand the twisting effect of the power transmitted as well as the bending action due to the wheel load.

Taking the case of ordinary shafting supported by bearings about 8 ft. apart, the diameter may be readily calculated by the following rule: Multiply the horse-power to be transmitted by 55, divide the result by the number of revolutions which the shaft makes in a minute, and extract the cube root of the quotient. A table is given on the next page of a

number of shafts already calculated by this rule and for various speeds.

The above rule is empirical, and is found in practice to give satisfactory results when used for ordinary line shafting; but in cases where a shaft is subject to specially heavy belt drives its diameter should be calculated from first principles—that is to say, the nature and the amount of the forces acting upon the shaft should be estimated, and the shaft be proportioned to resist them.

## Twisting Action.

The twisting action on a shaft is measured in "inch-pounds," or in "inch-tons," as may be most convenient. Taking the case of a shaft driven by a pulley, say, 36 in. diameter, having a turning

force at the rim of 350 lb., the "twisting moment," as it is termed, is  $18 \times 350 = 6,300$  inch-pounds; the figures 18 being the radius in inches at which the turning force acts. The

twisting moment on a shaft may also be easily determined from the horse-power transmitted and the speed in revolution per minute. Suppose

that a shaft is to transmit 20 horse-power at a speed of 120 revolutions per minute, the twisting moment =  $\frac{20 \times 33000 \times 12}{120 \times 3.1416 \times 2} = 10,504$  inch-pounds; 33,000 is the mechanical equivalent of a horse-power expressed in foot-pounds, and is multiplied by 12 to reduce it to inch-pounds; 3.1416 is the relation of the circumference of a circle to its diameter; the last divisor, 2, is necessary because the twisting moment is measured radially.

**The Resistance of a Shaft to Twisting.** In the same way as we may define a twisting moment acting on a shaft, so we may formulate a "moment of resistance" of the shaft itself which shall be equal and opposite to the twisting moment. The moment of resistance of a shaft to twisting is found by multiplying the "modulus for twisting" by the greatest allowable "stress" per square inch; the modulus for twisting is a mathematical function of the diameter of the shaft, and is represented by the formula  $\frac{3.1416}{16} \times d^3$

where  $d$  = the diameter of the shaft. A table of the moduli of various diameters with "moments of inertia" and "modulus" for bending is given on the opposite page, the use of both of which are discussed later. The greatest allowable stress per square inch depends upon the material of the shaft and upon the factor of safety decided upon. A safe stress for steel shafts is 10,000 to 12,000 lb. per square inch, which allows a factor of safety of about 5 or 6 to 1. Selecting as an example the shaft mentioned above, where a twisting moment of 10,504 inch-pounds was calculated, we divide that figure by a safe stress—say, 10,000 lb. per square inch

$\frac{10,504}{10,000} = 1.05$  modulus, which, upon referring to the table of modulus for twisting, we find is equal to  $1\frac{1}{2}$  in. diameter.

**Bending Actions on Shafts.** The bending action on a shaft is measured in the same units as a twisting action—i.e., inch-pounds or inch-tons; but instead of a twisting or shearing tendency being set up,

there is a tendency to snap the shaft off by crushing the fibres on one side and tearing them apart on the opposite side. A typical example occurs in an ordinary railway waggon axle [48], where the load on the journal is transmitted to the wheel by the axle; the "bending moment"

is here 4 tons  $\times$  10 in. = 40 inch-tons. Railway axles, on account of the heavy shocks they are frequently subjected to, must have a large margin of safety, not less than 9 to 1, equal to 3 tons per square inch for mild steel.

Dividing the bending moment by this allowable stress we get  $\frac{40}{3} = 13.3$  modulus. Now,

the modulus for bending has not the same value as for twisting, but is represented by the formula

$\frac{3.1416}{32} \times d^3$ ; the table

gives these moduli worked out for a number of different diameters. The figure we have arrived at, 13.3, is equal to, say,  $5\frac{1}{2}$  in. diameter, which, of course, is in the wheel seat. The diameter of the axle in the journal is more frequently

determined by the pressure per square inch rather than by bending stress, but this view of shaft design will be dealt with when we come to journals. It will be noted that in the table of moduli, etc., the letter  $I$  is given for the moment of inertia and the letter  $Z$  for the modulus; these letters are the recognised standard symbols for the terms.

It sometimes happens that a shaft is subjected to a combination of the above actions of bending and twisting at one and the same time; any shaft which receives or transmits power by a pulley, crank, or wheel on an overhanging end comes under those conditions. An example is shown in 49, which represents a spur wheel driving the drum shaft of a hauling gear. The twisting moment and the bending moment

48. RAILWAY AXLE

49. METHOD OF CALCULATION OF BENDING AND TWISTING FORCES

50. MUFF COUPLING

## DRAWING

must be so combined in calculation as to enable either one or the other modulus to be used. A simple and interesting method is as follows: From point A, the centre of the

keyed thereon. Two keys are used, and they are both driven from the same end; the shafts butt against each other in the middle of the coupling. A table is given on page 3134 of the

usual proportion of muff couplings for various sizes of shafts.

The split muff coupling is shown in 51. It has the advantage that it is easily fitted or removed; a single feather key is used, and the muff is bored so as to grip the shaft when bolted together.

Fig. 52 illustrates the most widely used

form of coupling. It is termed a flange coupling and consists of cast-iron bosses with flanges. The bosses are keyed to the ends of the shafts and the flanges are bolted together, a projection being formed on one half coupling to fit in a corresponding recess formed in the other half; this device ensures the correct alignment of the joint. A table is given of dimensions of flange couplings. Fig. 53 shows a similar coupling, but the outside diameter of the flanges is increased and also widened to protect the boltheads and nuts. By this provision accidents

bearing, describe an arc B C, bisect the horizontal line C D at E, then multiply the pressure or load at B by the distance E A; the result gives an equivalent bending moment to the combined actions, and the modulus for bending may be used. Or by calculation:

$$M = \frac{1}{2} B + \frac{1}{2} \sqrt{B^2 + T^2},$$

where M is the combined moment, B is the bending moment, and T is the twisting moment. This principle may be followed out for any combination of bending and twisting actions which a shaft may have to sustain. In some cases shafting may be loaded by pulleys or gear-wheels in the same manner that a beam or girder may be loaded [see MATERIALS AND STRUCTURES, page 1984 to page 1987]; but if the above principles be thoroughly grasped, the student will find no difficulty in dealing successfully with such problems. Naturally, in designing machinery, it is a constant aim to keep all pulleys, couplings, etc., as close to the bearings as possible in order to reduce bending moments. Marine engine shafts are calculated according to empirical rules issued by the Board of Trade, Lloyd's Survey, etc., and are dealt with in a later article on engine details; hollow shafting is also discussed later.

**Couplings.** A shaft seldom exceeds 30 ft. in length on account of the inconvenience of manufacture and the difficulty of erection or removal at site; means are therefore devised to joint or couple them together in convenient lengths. The simplest form of coupling is the muff or box coupling [50], which is simply a cast-iron sleeve bored out to fit the shafts and

51. SPLIT MUFF COUPLING

52. FLANGE COUPLING

53. PULLEY COUPLING

such as the catching of a workman's clothes, etc., are prevented; a coupling may also do service as a driving pulley when made in this latter form.

In cases where there must be no risk whatever of a breakdown—marine engine work for example—the coupling is formed by forging the flanges on the ends of the shafts themselves, and so eliminating keys and castings.

The universal coupling is indicated in 54, and is

used to couple shafts which are not in line with each other; it is very convenient for connecting shafting which drives machinery at varying angles, such as dredgers, etc., or where a certain flexibility

54. UNIVERSAL COUPLING

is necessary, as in the case of taking power from wind-mills or horse-mills to pumps, etc. The example given is for a shaft 3 in. in diameter; the pivot pins are half the diameter of the shaft, and the width of the jaw is twice the diameter of the shaft.

**Claw Couplings.** A class of coupling which is readily uncoupled is illustrated in 55, and a table is given on page 3134 of its usual dimensions; no bolts are used, but driving is effected by means of projecting claws which mutually engage. Such a coupling can be easily disengaged by drawing the key and pulling the claw faces apart; when this process is frequently required it is usual to make one half of the coupling to slide on a feather key and to arrange lever gear to facilitate the withdrawal. This type of coupling brings us to a larger group known as "friction clutches," but which are virtually couplings that can be engaged and disengaged whilst the shafting is in motion. They will be dealt with in a subsequent

article after we have completed the delineation of the simpler elements of mechanism.

**Journals.** A journal may be described as that portion of a shaft or axle which receives support from a bearing. After a shaft has been designed to have sufficient strength to transmit the loads imposed upon it, it is necessary to see that ample area is provided in its journals in order to ensure cool and efficient running. A journal must have sufficient area to dissipate the heat generated by the friction between it and its bearings. Good lubrication is a great factor in the

reduction of friction; without a lubricant of some sort a shaft would rapidly heat whilst running, and would soon grip or seize the bearing. With proper lubrication the following pressures per square inch of journal area are quite safe: Railway axles, 150 to 260 lb.; slow speed engines, 500 lb.; high speed engines, 250 lb.; ordinary shafting, iron bearings, 20 lb.; ordinary shafting, brass bearings, 40 lb.

A good rough rule for an ordinary journal revolving in a gun-metal bearing is to make the length  $1\frac{1}{2}$  to  $1\frac{3}{4}$  times the diameter; with cast-iron bearings the journal length may be  $3\frac{1}{2}$  to 4 times the diameter. The area of a journal, or a bearing, is calculated as the projected area—i.e., diameter multiplied by length.

The pressure between a journal and its bearing is not constant over the entire area; the greatest intensity occurs directly under the centre of the load, and it decreases circumferentially to zero at the half diameter. This is not considered when calculating the size of a journal in accordance with the preceding rules. There is also a similar variation in pressure—though to a much less extent—in the longitudinal direction; but a

55. CLAW COUPLING

mean pressure per square inch over the whole area is assumed.

*Continued*

## THE ETHERS AND THEIR USES

Ethers and Other Organic Compounds. The Nature and Value of the Ethers, Esters, and Mercaptans and Amines. The Various Kinds of Alcohols

By Dr. C. W. SALEEBY

PURE acetic acid is sometimes spoken of as a colourless liquid, and sometimes as a colourless solid, since below  $17^{\circ}\text{C}$ . it is solid, and is then called *glacial acetic acid*. It readily mixes with water, ether, and alcohol, and is useful as a solvent. The acid has a number of uses, both in medicine and in manufactures. In consequence of its affinity for water, glacial acetic acid has a marked caustic action upon the skin. It is sometimes employed also for the destruction of small warts and corns. Weak solutions of acetic acid or pleasantly scented vinegar are agreeable applications to the skin, which they tend to cool as well as to free from the unpleasant defects of excessive perspiration. It is stated in a well-known work of reference that acetic acid "is used in medicine to relieve nervous headaches and fainting fits," but this statement has really no relation to medicine of the present day, in which it is certainly not so employed. The acid has considerable uses in relation to calico printing, and is employed in the preparation of its salts, the acetates, which are of considerable importance in commerce.

**The Ethers.** If the reader will contemplate the little table to which we have already referred, and will compare the first and second columns, he will be able to remind himself of what we have already stated, that from one point of view the paraffins may be looked upon as analogous to metals, and the alcohols as none other than the hydrates of those metals, one of the hydrogen atoms having been replaced by the hydroxyl group OH. Now, if this manner of looking at these compounds be justified and not dependent merely upon a superficial resemblance, we ought to be able to carry the comparison a little further. If the paraffins are so much like metals as to form hydrates, they ought also to form oxides. If the hydrate is really a hydrate, it ought to be possible to remove from it the constituents of water and to leave the oxide behind. Now, this is possible. The term *ether* is a generic name used in organic chemistry for such oxides, and we might have inserted in our table [page 3020] a fifth column, showing the relationship of the ethers to the other four. What, then, will be the formula of the ether derived from methane? Plainly, in order to remove the constituents of water from methyl alcohol, the group  $\text{CH}_3$  being regarded as a unit which must not be broken, we must take two molecules and abstract  $\text{H}_2\text{O}$  from them. This will give us a body having the formula  $(\text{CH}_3)_2\text{O}$ . Similarly, in order to form the ether or oxide from ethyl alcohol, one has to take two molecules and subtract the constituents of water from them; the body thus resulting must have the formula  $(\text{C}_2\text{H}_5)_2\text{O}$ . These simple

examples correspond to bodies which really exist. If now we try to state the matter in more abstract terms, we may say that, if we use the symbol R to represent a one-handed or monovalent hydrocarbon radical (such as the methyl radical  $\text{CH}_3$ ), then the structure of an ether is represented by the formula  $\text{ROR}$ . An ether having such a constitution is technically called a simple ether. In the case of methyl ether, which is a simple ether,  $\text{ROR}$  is plainly equivalent to  $\text{CH}_3\text{OCH}_3$ . On the other hand, we need not necessarily have the same hydrocarbon radical repeated in the structure of the ether. The one might be the methyl radical, and the second the ethyl radical. The best general way of expressing the construction of such an ether would be  $\text{ROR}_1$ . An ether which contains two radicals in this fashion is conveniently distinguished as a mixed ether.

**Chemistry and the Simplicity of Nature.** It must surely have struck the reader that there is a remarkable simplicity underlying the apparent complexity of our subject. It is true that we are using long and complicated formulae, which would have alarmed us very much, and very naturally, had we been introduced to them a few months ago. But, on the other hand, these formulae undergo transformations in a very intelligible way, and, so far, possess relations with one another which can scarcely be forgotten. Indeed, this character of the organic compounds is sometimes almost conspicuously to be contrasted with the apparently arbitrary and capricious facts which we have often encountered in our study of inorganic chemistry. Here we are dealing, not with the theory of knowledge, but with a certain part of the subject matter of knowledge; yet, since all knowledge is one, we may be excused, even here, for pointing out the significance of the simple and reasonable relationships which rule the complexities that we are now studying. It may be doubted whether there is any study in the world which teaches us more clearly than organic chemistry, first of all, that, apparent or real complexities notwithstanding, the capricious and the arbitrary have no real existence, and, secondly, the truth of the great dogma of philosophy, that *Nature is intelligible by man's intelligence*. This is a simple statement and may sound like a jingle, but, if it be true, it is one of the greatest of all truths, and if it were false it would be one of the greatest of all falsehoods.

**Alkyls.** Perhaps the most convenient fashion in which to prepare the ethers is by the action of the iodide of methyl, ethyl, etc.—these radicals being ranked under the generic name *alkyls*—on the sodium compound of an alcohol. Thus,

for instance, when the iodide of methyl acts upon the sodium compound of methyl alcohol (the formula of which is simply that of methyl alcohol with the sodium atom in place of the hydrogen atom of the hydroxyl group) sodium iodide and methyl ether are produced. This statement really takes much longer to write or read than to understand. The reader should write the equation representing this decomposition for himself, and he will see how simple it is. Plainly, the methyl group of the iodide changes places with the sodium atom, and the thing is done. There are several other general reactions by which ethers may be prepared. Methyl ether, the formula of which we have already given, may be readily prepared from methyl alcohol, and is a gas above the temperature of  $-21^{\circ}\text{C}$ . If we start with a mixture of methyl and ethyl alcohols, we naturally enough obtain a mixed ether, which is called by the very explanatory name, *methyl-ethyl ether*, and with the formula of which the reader need not be insulted. This body boils at  $11^{\circ}\text{C}$ .

**Characters of Ethers.** In a moment we shall discuss the most important of the ethers; meanwhile, we note that, in general, these bodies are very mobile, colourless liquids, usually having a characteristic odour, while the higher ethers are white crystalline solids. The mobility of any of the lower ethers is striking, and the different characters of different liquids in this respect cannot be illustrated to the student of physics better than by three bottles containing respectively ether, water, and oil. The ethers are either insoluble or only very slightly soluble in water. In general the ethers are capable of oxidation and then form organic acids. They are, of course, combustible. One says "of course," since it is assumed that the reader will argue deductively from his knowledge of the constitution of the ethers. But in actual practice people sometimes forget, and the most lamentable accidents have followed upon carelessness in the use of ordinary ether in surgery and elsewhere. It looks more or less like water and causes forgetfulness of its properties. (The reader knows, of course, why water cannot burn.) If the ethers be heated with water in sealed tubes, an action which might have been expected occurs, recombination taking place and the alcohols being formed.

**Sulphuric Ether.** We have placed at the head of this paragraph the common name of what is by far the most important of all the ethers. It is commonly known as *ether*, and it is as such that we shall refer to it here. There is no proper warrant whatever for the name sulphuric ether, which gives one, at first, an entirely erroneous conception of its structure, and which is applied to it merely because sulphuric acid is employed in its manufacture. Its proper chemical name is *ethyl ether*, and its formula has already been stated. The process of its manufacture is typical of what is called *etherification*. This term is usually applied to the commercial manufacture of ether from alcohol and sulphuric acid. The reactions are very interesting. The first change which occurs

—under the conditions about to be stated—is an interaction between the alcohol and the sulphuric acid, with the formation of water and the body which has the formula  $\text{C}_2\text{H}_5\text{HSO}_4$ . This is sometimes known as *ethyl sulphuric acid*, or may be called a *hydrogen alkyl sulphate*. When this body is further distilled with alcohol, sulphuric acid is formed again and ether distils over. The reader should write out for himself the equations representing these two actions. He will find them extremely simple, only one molecule being required in each term. It will be found in the case of the first equation that the reaction causes the isolation of one molecule of water. If the reader does not follow our advice to write out the equations for himself, our policy of not stating them in full will have been rendered useless.

**Process of Etherification.** The following account of the actual fashion in which the continuous process of etherification is performed we quote from Sir Wm. Ramsay:

"In actual operations a mixture of alcohol and sulphuric acid is heated to  $140$  degrees in a capacious flask, and a slow stream of alcohol is run in; ether mixed with water and alcohol distil over continuously; hence this process is termed the *continuous etherification process*. A limited quantity of sulphuric acid should theoretically convert an unlimited amount of alcohol into ether; but, in practice, some of the sulphuric acid is reduced to sulphur dioxide, which distils over with the ether. To remove it, the ether is shaken with caustic soda solution, and to remove alcohol it is shaken many times with water. The surface layer of ether is then removed, dried by adding lumps of fused calcium chloride and leaving it to stand, and is finally redistilled from phosphorous pentoxide."

The ether thus formed has the characters belonging to its series. It boils at about  $35^{\circ}\text{C}$ ., and the vapour which it gives off at this quite low temperature is extremely inflammable, like the liquid itself. Not infrequently people remember that the liquid is inflammable, but forget the danger which attaches to its vapour. Ether is very slightly soluble in water, but readily mixes with alcohol and chloroform. A mixture of these three substances is known as A.C.E. mixture, and is very frequently used as an anæsthetic in surgery. Ether is one of the most important of solvents, and notably so for fats. This gives it another value for the surgeon, who often uses it in order to remove from the skin its natural fat, in which bacteria multiply so abundantly. Ether also dissolves resins, and is much used for this purpose in chemistry and in pharmacy. Owing to its extremely rapid evaporation at relatively low temperatures, ether affords a very effective means for the production of extremely low temperatures. The reader will recall the application of this property of evaporation in a physical instrument.

**The Practical Use of Ether.** But, after all, the most important and interesting of all the uses to which ether is put is as an anæsthetic. A long time ago we had occasion to refer to nitrous oxide,  $\text{N}_2\text{O}$ , which may fairly be called

the oldest anæsthetic—at any rate it has the first place in the modern history of anæsthesia. It was first inhaled by Sir Humphry Davy in the year 1800, and he suggested its employment in surgery: “As nitrous oxide in its extensive operation seems capable of destroying physical pain, it may probably be used with advantage in surgical operations in which no great effusion of blood takes place.” Thus the great chemist did his duty in calling the surgeons’ attention to the matter; but they paid no attention to the suggestion. Eighteen years later another illustrious chemist and physicist, Faraday, proved that ether, like nitrous oxide, produces anæsthesia.

### The “Chemistry of Consciousness.”

Even then, however, such is conservatism at its worst, surgeons made no response. It was not until 1846 that Morton, a dentist at Boston, successfully administered ether for the extraction of teeth and for other operations. Two or three months later, Sir James Simpson made the first employment of ether in cases of childbirth, and followed this up after a very short time by the discovery of the anæsthetic value of chloroform. In the case of nitrous oxide we made a point of showing that a chemical explanation can be afforded of its anæsthetic properties, and also of the very great safety which attends its use. It must positively be insisted that, beyond all question, a chemical explanation must also be expected to account for the arrest of consciousness by the inhalation of ether into the blood. But in this case we are as yet quite at a loss to offer this explanation. It is scarcely surprising if we remember that the chemistry of consciousness is yet entirely unknown; indeed, so far as the present writer knows, this is the first occasion on which the phrase has been employed.

An interesting example of the use of ether in dissolving the most intractable of substances may be found in the preparation which is called *collodion*. Cotton-wool is subjected to the action of sulphuric and nitric acid, producing the substance known as *pyroxilin*. This is dissolved in a mixture of ether and alcohol, and is then known as *collodion*. A large number of other substances may be included for special purposes. When this is painted upon the skin the ether rapidly evaporates, the pyroxilin being precipitated in the form of a thin protective film, which has many useful functions.

**Ethereal Salts.** We may actually go yet a little further in our discussion of the analogy between the paraffins and metals. We have said that an alcohol is a hydroxide or hydrate, and that an ether is the corresponding oxide. If, then, we have ethyl hydrate and ethyl oxide, why should we not have, for instance, ethyl nitrate; in other words, if the analogy be more than superficial, the ethers should act like other oxides and form salts, and, in fact, they do so. These salts may be called *etheral salts*, or they may be called *compound ethers*—a term which introduces confusion with “mixed ethers”—or they may be called *esters*. This term is now widely employed. An ester, then, is a salt in which

the base is derived from a paraffin. The term is best confined to the ethereal salts of organic acids.

The salts formed by interaction between ethers or alcohols and inorganic acids may be briefly dismissed. Reference has already been made to the halides of methyl and ethyl. Similarly, many other organic acids have formed corresponding salts. The nitrates, sulphates, phosphates, etc., of various alkyls, or alkyl radicals are well-known. The common manner of their formation is by the action of the acid on the alcohol. One of the most familiar substances is *ethyl nitrate*, which is often known as *nitric ether*. Another, which is of considerable value in medicine, is the *nitrate of ethyl*, which is a highly inflammable, mobile liquid with a very pleasant, fruity odour and taste. Its characteristic interactions with the body, however, are those of a nitrite—in other words, they depend upon the acid rather than the basic part of its constitution. The familiar drug known as *sweet spirits of nitre*, owes all its value to ethyl nitrite, of which it contains about two per cent., together with a large number of impurities. Properly, sweet spirits of nitre should be abolished from the Pharmacopœia, and its place taken by the pure solution of ethyl nitrite.

Of the esters, properly so-called, little more need be said. Perhaps the best known is *ethyl acetate*, the formula of which is that of acetic acid, already quoted, the ethyl radical being substituted for the final H of that formula. This body is often known as *acetic ether*, and has a very pleasant odour. This last character is common to most of the esters, which are therefore very often employed in sweetmeats, and upon which depends the characteristic fragrance and taste of many fruits and wines.

### The Mercaptans and their Products.

Yet further may we carry our proof of the rational character of organic chemistry. Long ago we saw that sulphur and oxygen, widely though they differ in their physical characters, yet have a definite chemical resemblance to one another, and may be treated as a pair of allied elements. The simplest possible illustration of this is to be found in the resemblance between the formulae of water and of sulphuretted hydrogen,  $H_2O$  and  $H_2S$ . Now, in accordance with the truth that there are not two chemistries but one chemistry, the same holds good in the case of organic compounds. It ought to be possible to form compounds analogous to the alcohols, but having sulphur in place of their oxygen atom. This is indeed so. The various members of the series of mercaptans are colourless liquids, almost insoluble in water, and having an extremely objectionable smell, such as is so often associated with the compounds of sulphur. The second mercaptan, to take an instance, is known as *ethyl hydrosulphide*, and has the formula  $C_2H_5SH$ . This shows at a glance its relation to ordinary alcohol. The peculiar name applied to these bodies is derived from a phrase expressing their *aptitude* to act upon *mercury*, or rather upon mercuric oxide.

They form a series of compounds, in which an atom of mercury takes the place of the hydrogen of the SH group.

It might reasonably be expected that the various alkyls would form sulphides analogous to the oxides or ethers which we have already studied, and this is so. If an S be substituted for the O of the formula of ether, we have the formula of ethyl sulphide, which, as might be expected, is characterised by its horrible smell.

If the hydrosulphides of the alkyls—the mercaptans—be oxidised, they yield a series of acids which are known as the *sulphonic acids*. A study of certain of these proves that there are really two distinct varieties of what we have hitherto referred to under the single name of sulphurous acid.

### The Two Kinds of Nitrous Acid.

As to this, we need not go any further, since the case is the same with nitrous acid, as we are about to show. If we take the iodide of an alkyl—as, for instance, ethyl iodide—and heat it in the company of nitrite of silver, we get a double decomposition which results in the formation of iodide of silver and what, from the appearance of its formula, ought to be ethyl nitrite. And, indeed, it is entitled to the name of ethyl nitrite, but it is by no means the same substance as that which we have already described under this name. The equation representing its formation reveals no distinction. It runs, of course, thus:

But, as a matter of fact, the ethyl nitrite thus formed has a boiling point of  $112^\circ \text{C}.$ , whereas that already described has a boiling point of  $16.4^\circ \text{C}.$  Plainly, they are “the same but different,” and we shall soon see that this sameness with a difference is an illustration of *isomerism*. The two bodies are called *isomers* because they have “equal parts.” The shortest statement of the formula expresses this; the molecule of each consists of the same numbers of the same atoms. If, then, two substances have “equal parts,” but are not the same, there is only one explanation of the difference—it is that the parts are differently put together. We can only conclude, then, that the  $\text{NO}_2$  group is not the same in the two cases. The question is to find out where the difference lies.

### Reactions of the Two Substances.

We can do this by comparing the reactions of the two substances. Ordinary ethyl nitrite, under the influence of caustic potash, yields potassium nitrite and ethyl alcohol. This new ethyl nitrite, however, acts differently, the potassium atom of the caustic potash changing places with one of the hydrogen atoms of the nitrites so as to yield water and a new body, the formula of which the reader can write for himself. Furthermore, if this new ethyl nitrite be subjected to the action of nascent hydrogen, it forms a new substance, which we shall shortly study, called *ethylamine*; in this respect, also, it acts differently from ordinary ethyl nitrite. We must therefore no longer call this body ethyl nitrite, but must give it a new name, *nitro-ethane*; and

we must find in the differences between it and true ethyl nitrite materials which lead us to conclude that there are really two nitrous acids; the formula of one may be written  $\text{HONO}$ , and of the other  $\text{HNO}_2$ .

The preceding paragraph has an importance greater than that of the particular statements which it contains. It teaches us to understand the dangers of brevity, or, to be more explicit, the dangers of statements so summary that they cloak important distinctions. The formula  $\text{HNO}_2$  is thus too summary to be accepted without criticism. We have to recognise that it may stand for either of two molecules which are, indeed, isomeric, or have equal parts, but which are not identical any more than the state of affairs when the cards are dealt at whist is always identical because the same fifty-two cards are present in every case, or any more than vile and veil are the same word because they are composed of the same letters.

**The Amines.** We have seen that one of the arguments for the true character of nitro-ethane is derived from its behaviour with nascent hydrogen. The substance produced, ethylamine, has the formula  $\text{C}_2\text{H}_5\text{—NH}_2$ , and may be taken

as typical. It may be looked at in two ways, as the formula indicates. On the one hand, we may say that it is no other than a substituted ammonia—that is to say, it is simply ammonia which has had one of its hydrogen atoms exchanged for the ethyl group. This is a fair way of looking at it, and is justified by the fact that ethylamine and ammonia closely resemble one another. For instance, just like ammonia, ethylamine unites with hydriodic acid, forming ethyl ammonium iodide. The formula of this body is  $\text{CH}_3\text{—CH}_2\text{—NH}_3\text{I}$ . That has a formidable appearance, but it was certainly not worth writing down for the student who has carefully followed each stage in the preceding argument. Just as ammonium chloride yields ammonia when acted upon by caustic soda, so ethyl ammonium iodide yields ethylamine under a similar influence. Further complexities, which are not difficult to understand, are yielded if we adopt means for doubling the number of ethyl groups. For instance, if we heat ethylamine and ethyl iodide we obtain a compound which, when treated with caustic potash, gives us diethylamine. The first ethylamine we should really have called *monethylamine*. We can go on much

further in this direction, producing the hydriodide of triethylamine, and may go even further still. The accompanying graphic formulæ, in the first three of which nitrogen is three-handed and in the fourth five-handed, show us the relation of these various substances to ammonia. The last body of which the formula is drawn has the apparently formidable name *tetrethyl*—that is, four ethyl—*ammonium iodide*.

On the other hand, we may with equal propriety look upon the amines as substituted ethane. It is just as correct to look upon ethylamine as ethane, of which one hydrogen atom has been replaced by  $\text{NH}_2$ , as it is to call it ammonia, of which one hydrogen atom has been replaced by  $\text{C}_2\text{H}_5$ . Many amines are known to occur in nature, and many more have been prepared. They all smell very like ammonia.

**The "Reasonableness" of Organic Chemistry.** Lastly, we may note that our old statements as to the nitrogen group find support even in this field. If those statements were valid, we might expect to find a group of—for instance, phosphines and arsines, corresponding to the amines; and this is so.

So reasonable is organic chemistry, so intelligible by man's intelligence, that it is constantly yielding the most remarkable confirmations of *à priori* reasoning. Time and again the chemist says "there ought to be such and such a compound; it ought to have such and such characters; it ought to be capable of preparation in such and such a way." And when he sets to work he finds his predictions verified.

Even yet we have not adequately discussed the many products of the paraffins, and the main facts of a few more of these must be considered.

**Some New Alcohols.** We have already discussed a whole series of alcohols in general, and the most important member of that series in particular. We have seen that these alcohols may be regarded as analogous to hydrates or hydroxides. We have now to learn that this series of alcohols is not the only one. There are also two other series which must be named, though they are not of so great importance. The series to which ordinary alcohol belongs are more properly to be called the *primary alcohols*. There are also *secondary alcohols* and *tertiary alcohols*, according as two or three, instead of one, hydrogen atoms are replaced by alkyls. These have very similar properties, and also form intelligible series. One of the means of obtaining primary alcohols consists, as we are already in a position to understand, of the addition of hydrogen to aldehydes, which are dehydrogenised alcohols. We have now to learn that just as the *aldehydes* correspond to the *primary alcohols*, so there correspond to the *secondary alcohols* another series of bodies which are nearly related to the aldehydes, and are

called *ketones*. All these alcohols—primary, secondary, and tertiary—we must note, are really no more than three groups of one, particular class of alcohols which are called *monohydric*.

**Dihydric Alcohols.** In the monohydric alcohols only one atom of hydrogen of the original paraffins has been replaced by the hydroxyl group—OH. This is why they are called *monohydric*, or one hydric. Now, there is no *à priori* reason why it should not be possible to replace a second of the hydrogen atoms by hydroxyl. All the hydrogen atoms of methane, for instance, are identical in their relations within the atom. There is no reason why any one of them, rather than any other, should be replaceable by hydroxyl. The dihydric alcohols, then, are those which contain a second hydroxyl group. There are two kinds of these dihydric alcohols, as might be expected if we looked at the graphic formula of a paraffin. We should then see that a dihydric alcohol might be formed, in which one and the same carbon atom had both hydroxyl groups attached to it, while, on the other hand, the hydroxyl groups might be attached to different carbon atoms. The first group are called *aldehydrols*, and the second are called *glycols*. One or two examples of these bodies may be noted.

**Chloral.** Everyone, unfortunately, has heard of this powerful hypnotic, the use of which is attended with so many dangers of forming an incurable and fatal habit. The full name of chloral is *trichloraldehyde*. When this body unites with water it forms an aldehydrol, which is indeed the best known member of the series. (It is really the chlorine compound of the aldehydrol.) This aldehydrol, formed by the union of chloral and water, has the alternative name of chloral hydrate. In medicine and in common speech it is usually known merely as *chloral*, but that, of course, is incorrect; the substance is not chloral or trichloraldehyde, but is that body plus water. In other words, it is an *aldehydrol*.

This, then, is the second substance, the reader may have noted, which contains chlorine, and which has a peculiar action upon the nervous system—chloroform, of course, being the other. Now, it is a remarkable fact that many others may be added to these two. For instance, methyl chloride, ethyl chloride, and several allied substances containing chlorine are either anæsthetics (general or local) or hypnotics, or combine both actions. This is a series of facts which obviously points to some larger meaning that will doubtless be familiar to the chemist of the future. We might venture to lay down the generalisation that the chlorine derivatives of the paraffins tend to interfere with the activities of nervous tissue. But the chemical explanation of this fact is not yet forthcoming.

# ARCHES, VAULTS, AND DOMES

The Construction of Arches. Barrel, Groined and Ribbed Vaults. The Construction and Supports for Domes

Group 4  
BUILDING

22

Continued from  
page 1640

By Professor R. ELSEY SMITH

**Arches in Masonry.** In masonry walls, openings, where they occur, are, unless covered with a flat stone head or lintel, spanned by some form of arch. The shape that it takes varies with the style of architecture employed; but any form of arch that can be constructed in brick may be equally well constructed in stone. It is not usual, as already pointed out, to form a flat arch in stonework, though this may be done if necessary with stones joggled together, as in the case of terra cotta [page 2780]. In certain styles of architectural treatment, however, an opening covered by a square or very slightly cambered head may have this formed of several stones; but where this is done it is usually for the sake of special architectural effect and not as a constructive necessity, a bold effect being produced by using a large keystone and on each side of it voussoirs not uniform in height but graduated so as to be reduced as the springer is approached [162, page 3039].

**Lintels.** In most positions where a flat soffit is required, a single stone may be employed for all openings of ordinary width; but it is not desirable to use stones of very great length in comparison with their height, whether used to cover an opening or in the body of a wall, owing to the risk of fracture in case of any settlement; it is generally considered that in stone of a weak character the length should not exceed four times its depth, and in the case of a strong stone the length should not exceed six times its depth when used as a lintel, and where built into a wall the proportion is sometimes restricted to three times the length owing to the difficulty of securing the even bedding of long stones with thin mortar joints.

It may sometimes happen, in the case of a square-headed opening or of an architrave block supported by a row of columns, that stones cannot be obtained of sufficient length to reach between the supports, and where such a support is enriched with a band of horizontal mouldings it is not desirable to cut the face into the form of a voussoir as the joint would then cut all the mouldings at an angle and produce in one of the stones a *feather edge*—that is to say, an angle less than a right angle; in such a

163 / SECRET JOGGLE JOINT

case the stone may be worked with a vertical joint on the face and have behind it a very large voussoir-shaped joggle formed [163], which fits into a corresponding sinking in the adjoining stone and forms, in fact, a flat arch,

though it does not show as such externally. When this construction is used it must be recollected that a lateral thrust is exerted and a strong abutment is essential.

**Voussoirs.** In arches of stone the blocks of which it is composed are fewer and larger than in the case of a brick arch. They are all dressed for their position and may, therefore, be given the shape of a voussoir quite as easily as that of a parallel-sided block; and this is invariably done, the two sides of the voussoir representing two lines radiating from the centre from which the arch is struck, and a fine mortar joint is employed.

**Strength of Arches.** The load on the blocks forming an arched structure increases towards the springing of the arch, and in theory the strength of the arch should be gradually increased from the crown towards the springing by increasing the depth of the voussoirs.

Rankine gives the following formula for calculating the depth of the voussoirs. Depth of the crown or keystone

=  $\sqrt{0.12 \times \text{radius of arch at crown}}$   
in the case of a single arch, and in the case of a series forming an arcade

=  $\sqrt{0.17 \times \text{radius of arch at crown}}$ .  
This applies to masonry of the highest class, and for masonry of second quality the depth as thus calculated should be increased by one-eighth and for brickwork and for masonry of poor quality by one-fourth. Where the depth of voussoirs is increased towards the springing the amount of the increase varies from one-fourth to one-half, but for arches of moderate span, including all those used in ordinary building construction, this is not usual, and would not be suitable in the case of work moulded on the face except where the moulding was confined to the lower edge.

The following table gives the usual sizes of stones used in constructing semicircular arches for spans up to 24 ft. of a good class of masonry.

|              |       |    |       |
|--------------|-------|----|-------|
| * Span up to | 6 ft. | .. | 9 in. |
| " "          | 10 "  | .. | 11 "  |
| " "          | 16 "  | .. | 14 "  |
| " "          | 18 "  | .. | 15 "  |
| " "          | 24 "  | .. | 18 "  |

\* "Notes on Building Construction"—Rivingtons.

**Skewbacks.** In the case of all stone arches, except those which spring from a horizontal bed at the level of the centre or centres from which the arch is struck, a skewback must be provided, as in the case of brick arches under similar circumstances; but it is usual in most stone arches to give a much greater rise than is the case with the ordinary brick arch. In any form of rubble wall the skewback is cut in a

single springer or springing block, corresponding with the depth of the arch to be used; this is built into the wall and forms part of the dressings of the openings, and it is not usual to form the skewback in the rough walling as is done in brickwork.

**Size of Voussoirs.** The voussoirs are not necessarily all of the same width in face, and in Gothic work vary considerably; but for many styles of architecture it is necessary that they should be uniform, especially if the joints are strongly marked. In some forms of arch the voussoir has not a curved extrados, but

164 ARCH WITH VOUSSOIRS CURVING WITH AXILAR

is set out so as to present a vertical and horizontal bed, and to bond with the courses of which the wall is built [164].

In many cases the voussoir extends through the whole thickness of the arch from the face to the back of the arch, and this is usual in all buildings of a classical or Renaissance character.

In arches belonging to the Gothic periods, in which the moulded surface is much deeper, a section taken through the arch displays not a single stone; but two or more consecutive rings or orders of stone, each containing a group of mouldings, and these rings are, except in the case of the innermost one, made up frequently of two or more stones in their thickness [165]. In cases where the opening is filled in with tracery, the thickness of the stones forming this corresponds

165 ORDERS OF A GOTHIC ARCH

usually with the thickness of the innermost order of the arch, and the tracery itself is built up of separate blocks of stone, some of which are simple, and others complicated, but so arranged and jointed as to form portions of the main or subordinate arches. The joints in each case are formed, as in the case of a simple voussoir, by a line drawn from the centre from which the curve is struck.

**Keystones.** In many forms of arch, the keystone is given considerable prominence and importance, and is frequently deeper than the other stones of the arch [162, page 3039]. It may stand forward beyond the general face or be carved, or otherwise enriched; this is in no way essential to its structural use, but, being a stone of special importance, it is selected as a fitting object for some special notice and enrichment.

In the case of arches that are pointed in form, as used throughout the Gothic periods, the apex, as a rule, is not formed with a keystone, but with a vertical joint. The arch is not formed of a single simple curve, completed by the keystone, but of portions of two curves which are not complete, and give each other mutual support through their abutting one against the other at the apex. In the same way a single half arch may be made to abut against the vertical face of a wall requiring support, as in the case of a *flying buttress* [168 E].

**Vaults in Masonry.** Vaulting in masonry has three main divisions—the *plain* or *barrel vault*, the *plain groined vault*, and *ribbed vaulting*, each of which has various subdivisions. The simplest form, that of the barrel, which may be semicircular, pointed or elliptical in section, is in fact an arch with a very wide soffit, and, like an arch, is constructed on a temporary centre [page 2386], but instead of being formed of single voussoirs it is built of courses of stone, each of which is, in cross section, of voussoir shape, and the crown of the arch is formed, not by a single keystone, but by a course of stones forming a key.

**Intersecting Vaults.** If such a continuous vault be intersected by one or more vaults which run at right angles to the main one, we have introduced at once an element that in some way adds to the difficulty of construction. This is not the place to consider the geometrical forms produced by such intersection, but they will be dealt with elsewhere, and it will suffice to point out here that if the two intersecting vaults are precisely similar in cross section, and spring from the same level, their intersection will produce on plan a line lying in a single plane, but that if there be any difference in the size or form of the two intersecting vaults, the line of intersection will be not a straight line on plan, but a sinuous one. Any such vault is termed a *groined vault*.

The mason will have to determine the exact form this line of intersection will take, and to prepare a series of moulds for those blocks which form the angle between the two adjoining vaults and which will usually vary for every separate stone.

This is particularly complicated when the intersecting arches are not identical in section, and it affects the sizes of the stone courses in the two separate vaults [see *Drawing for Masons*]. The actual working of the stones when their true form has been set out presents no special difficulty, and except at the angle, the stones in successive courses will be similar to the stones in a plain barrel vault. The centres for fixing must be prepared specially to the required form of the groin to be employed [pages 2385-6]. In construction, considerable care is required in forming the groins to see that the individual stones are properly bedded, that they bond with the courses in both vaults, and that the joints are well formed, as much of the strength of the vault depends upon these groins. As a rule, where a groined vault is used, there is no moulding of any kind at the angle, but occasionally a

**moulding of slight projection occurs which stands below the general surface of the stone and must of course be kept of uniform width. This is worked on the stone that forms the angle. Notwithstanding the introduction of ribbed vaults during the period of Gothic art, groined vaults continue to be employed for work having certain architectural characteristics, but cannot be applied with the same facility to cover areas that are irregular in plan.**

**Ribbed Vaults.** The ribbed vault was introduced during the early development of Gothic architecture and is structurally a great improvement upon the groined vault [168 F]. Vaulting ribs in the simpler form of vaults consist of stone arches, of which the lower edge may be moulded and the back may be cut to the form of a skew-back or rebate to receive the stones of each surface of vaulting lying between two ribs. As in the case of other pointed arches, each half may be considered by itself, and, if the whole system provides proper abutment, it is not essential that the various ribs forming a vault should be exactly opposite to each other. In vaulting a space, the plan of which is irregular, every rib may differ in actual form, and yet all be arranged to extend to the crown of the vault, where it is usual to provide a large central stone against which every rib abuts and which is held in position by their united thrusts.

**Use of Stone Bosses.** When several ribs abut against such a stone, to avoid the complicated intersection of mouldings that would result it is usual to project the under surface downward below the level of the ribs and to enrich it with carved foliage or figures or both, and to allow the ribs to stop against the edge. Such a stone is generally termed a boss, and is in effect a central abutment common to all the ribs [168 G].

**The Vaulting Rib.** Each of the individual ribs is, as a rule, a segment of a circle, and the lower end rises from the support from which it springs; in most cases the centre from which the curve of the rib is struck is on the level of the springing, the upper end abutting against the boss. The line of every main rib lies in a true plane between the springing and the boss or apex. The rib or arch is formed of a series of stones formed of voussoirs, but when several ribs spring from the same column, as occurs in many vaults, there is often not room on the capital for the whole depth of each rib to start separately and distinct from each other, especially where they are deep and richly moulded; in this case some of the mouldings in each rib are allowed to die out, the most prominent mouldings only in the lower edge being allowed to run down to the capital [168 G]. The working of these lower blocks is a matter requiring much skill, as it is difficult to prepare bed moulds showing the moulded ribs as they die away, except at the level of the upper and lower beds of each stone.

The preparation of these moulds is complicated by the fact that the beds of the stones for a certain height above the springing are not worked on radial lines, but are horizontal beds, so that the section of the mouldings is not a true section.

The height to which these horizontal beds are carried above the capital is not uniform, but depends on the circumstances of each case.

They usually extend to such a height as will admit of each rib becoming completely disengaged from its neighbour. Until this occurs it is almost impossible to provide radiating joints for several ribs of different curvature, when they have all to be worked in a single block of stone. These massive blocks above the capital form an abutment to receive the thrust of the ribs and vault above, and, in planning the vault, it is essential that thrusts on these lower stones from different quarters should practically counterbalance each other, for if this be not so, the stones would be displaced by any excessive thrust from one direction.

**Resisting the Thrust of a Vault.** It is of equal importance to provide an effective resistance to the whole thrust of a vault composed of a series of ribs with the filling in between them, and which, if erected against a wall or pier at a point high above its base, would tend to thrust it outwards or overturn it. This thrust may be counteracted by the introduction of metal ties holding together the two piers in which the arch rests, so that they cannot spread [168 F]; this, though structurally efficient, is unsightly, and in the finest monuments of the mason's art is never employed.

Failing such a tie, the thrust exerted high up in the wall must be carried down to the level of the ground by a suitably designed mass of masonry known as a *buttress* [168 D and E]. Such a buttress will serve to counteract the tendency exerted by the vault to overturn the wall, either as the result of the total weight of a great mass of material employed or of the skilful disposition of a smaller mass. For further particulars as to the stability of arches and vaults, see MATERIALS AND STRUCTURES [page 2760]. It should be pointed out that the necessity of providing these massive abutments affords the mason a magnificent opportunity of exhibiting the extent to which his art is capable of rendering beautiful and effective structures which in their origin are purely utilitarian; this may be seen by the examination of any good examples of a vaulted building, in which the buttress invariably forms an important element in the external design.

**Constructing the Vault.** The actual construction of a ribbed vault is a feat of considerably less difficulty than the construction of a groined vault of the same dimensions. The ribs may be first erected as simple moulded arches on ordinary centres, and may be carried up for some little distance without any centring; the groundwork of the vault is thus formed, and the general filling in of the cells between every pair of ribs can be carried out with comparatively slight centring. The ribs are, as already explained, provided with skewbacks or rebates to receive the filling, the surface of which may be adjusted where required to fill exactly the spaces formed by the ribs [168 G]; these surfaces in some cases exhibit a very considerable twist.

The filling is, where possible, of a light material, as no very great strength is required, and the

upper surface or back is always protected from the weather by an external covering, usually a roof above the level of the crown of the vault. In some old examples of considerable span the filling is not more than 4½ in. thick, and 6 in. is a very usual thickness. Where several ribs rise from a single pier in different directions, a kind of pocket is formed between the main wall and the thin shell formed by the ribs and their filling in. This must be filled in solidly with concrete to a level that varies somewhat in different cases but need not exceed, as a rule, a point on the rib about one-third of the distance from the springing to the crown. The object of this filling is to prevent any tendency of the arch or vault to fail at the haunch by buckling or bending when the vault is completed and the full load comes upon it.

In some of the later Gothic vaults the ribs are very numerous, and when they are formed close together, the filling in between adjacent ribs may consist of a single stone extending from rib to rib for a considerable proportion of the total height.

**False Ribs.** In the elaborate vaults over small spaces such as occur in chantries, canopies over tombs, and in similar positions, the distinction between the rib and the panel is lost sight of, and the vaulting rib becomes merely a surface enrichment without any structural importance, the vault being formed of large stones carved on the under side into the representation of a ribbed and panelled vault [168 B].

**Stone Pendant Vaults.** Occasionally, where pendants are employed in vaulting, stonework is submitted to a direct tensile strain. A well-known example is the roof of Henry VII.'s Chapel at Westminster Abbey, in which a considerable proportion of the vault depends for its support on long stone pendants; the upper ends of these are built into the main transverse arch of the vault, the bottom of the stone being several feet below the soffit of the arch, and forming a base from which several vaulting ribs are sprung. This expedient is not very frequently adopted, but if used, care must be taken to see that such stones are perfectly free from any flaws or defects [166].

166 VAULTING PENDANT

**Domes.** Domes are vaults, circular on plan, and may be constructed like a plain barrel vault, without any break in the surface, and a perfect hemisphere may thus be formed. The oldest existing dome on a large scale is probably the structure at Mycenae, in Greece, 48 ft. 6 in. in diameter, and not semicircular, but pointed in section. The construction of this, however, differs from that of most domes in that the successive courses are not formed with radiating beds, as in a voussoir, but with nearly or quite horizontal ones.

In ordinary dome construction every course is formed of a ring of stones of uniform height, of which the heading joints all radiate on plan from the centre from which the dome is struck. If a section be taken through the dome at any point, the successive courses will appear exactly as in the case of an arch with radiating joints, forming in effect voussoirs, and each course forms, as it were, when completed, a circular voussoir formed

167 SECTION OF A DOME

of a ring of stones. The back of each course may be worked to give a stone of uniform thickness, or if the exterior is to have a separate roof covering the top may be formed horizontally, and the back vertically, as is done in some forms of arch [167].

Where the section of the dome is that of a semicircle or a segment of a circle, the courses, if equal in height, may be worked from the same section moulds; but should the section of the dome be that of an ellipse, separate moulds must be provided for each course, and, in any case, the face moulds must be varied, owing to the reduction in diameter of every successive course.

**Heading Joints.** As a rule, in a masonry dome the heading joints in alternate courses are required to be in the same vertical plane, to secure regularity in the appearance of the surface work, just as in the finest ashlar work all heading joints in alternate courses are vertically one above another; but as this would result in the use of very narrow stones in the innermost rings, it is usual to reduce the number of stones and joints in these rings, but those joints that are used correspond with joints in the lower courses.

**Construction of Domes.** In constructing domes the stones of successive courses have the heading joints joggled together, and the lower courses at least have dowels in the beds of the stones. A centre is necessary during construction, which must be circular on plan, corresponding with the form of the dome.

Such a dome exerts a thrust, which is not like the thrust of a groined vault concentrated at certain well defined points, but exerts an outward pressure throughout the circumference, and must be effectively resisted if the structure is to be stable.

Various methods for resisting this thrust have been adopted, and the joggling of the stones and the dowelling of the successive courses greatly helps towards this end. One method, adopted in the dome of St. Paul's Cathedral as an auxiliary method is to build in at the base of the dome a strong iron chain passing entirely around the circumference; another similar method is to bed a broad but shallow circular iron plate at the base of the dome; but both of those are open to the objection that, should moisture penetrate to the ironwork and corrosion take place, the tie may be a source of danger rather than a benefit.

A heavy mass of masonry boldly projecting internally within the case of the dome has been

**168. DOMES, BUTTRESSES, AND VAULTS IN SOME IMPORTANT BUILDINGS**

successfully employed, the weight of the overhanging mass being utilised to counteract the natural thrust of the dome; this method permits of the complete external form of the dome being seen. The base of the dome is in some examples greatly thickened, securing a considerable mass of masonry near the springing, but this conceals the external form. In some cases the base upon which the dome rests is secured by half domes or arches at a lower level, which effectively buttress it. And masses of masonry similar in effect to Gothic buttresses but differing in form are also employed.

**Double Domes.** For St. Paul's Cathedral, London, the masonry dome visible in the building is surmounted by another dome at a higher level, which in this particular instance is of timber covered with lead, the object being to produce a fine external as well as internal effect, which is rarely possible with a dome of uniform thickness; this system has been employed with variations in several other domes constructed lately.

**Ribbed Domes.** The internal face of the dome is not necessarily a plain circular vault as already described, but may have ribs formed in its under surface extending upwards from the springing and dividing the interior into compartments. These do not extend, as a rule, to the centre of the dome, where they would become too narrow to be effective, but are stopped by a moulded band at a point some distance below the crown of the dome. This treatment may, in particular, be usefully employed where it is desired to form a central opening near the crown of the dome to admit light by means of a lantern light, the ring of stones which form the opening being of extra depth and serving to stop the moulded ribs.

**Coffered Domes.** Another method of enriching the inner face is by the use of sunk panels or *coffers*, either between such moulded ribs as have just been described, or as the sole decoration; they form a series of compartments surrounding the dome, of which the upper and lower edges are horizontal and the sides converge somewhat owing to the form of the dome, as a result of which also the width of the coffers in each succeeding row becomes diminished, and the height must be correspondingly reduced. It is also necessary to bear in mind in working such coffers that the moulded sides are not all equally displayed, as in the case of a coffer sunk in a flat soffit, but that while the sides and upper part of the panel are fully seen from below, the lower edge of the panel will cut off from view the inner range of mouldings if they are worked to the same section as the other sides; and it is, therefore, usual to increase the width of each moulding

in working it, so that it may be visible as a completely moulded panel from below. The amount of this correction necessarily varies in the different panels, being greatest in the lower ones, the position of which is nearly vertical, and comparatively less in the upper panels, which, as they become approximately horizontal in position, will need no great adjustment.

#### Methods of Supporting a Dome.

A dome must of necessity spring from a circular base, but in many positions it is impossible to carry down such a base to the ground level, and at this stage isolated piers are provided to support the superstructure. These piers may be four, six, eight, or even more in number, but the use of six or of more than eight is rare. If arches are thrown from pier to pier carrying walls a base, square, octagonal, or polygonal, is formed, and it is necessary to convert the form thus arrived at into a circle. In the case of an octagon, the difference between a circular figure and an octagon circumscribed round it is nowhere very great, and the circle may be arrived at by corbelling or a gradual change of the surface. Where a square base, however, supports a circular one, the difference between the two on the diagonal is considerable. One method of dealing with the angle is to throw a series of arches across it, each ring corbelled out beyond the one below, till an octagon is formed, from which the circle is arrived at.

**Pendentives.** A usual method is to employ the form known as a *pendentive*; this takes the form of a spherical triangle, and occupies the approximately triangular spandrel formed between two arches placed at right angles on plan and the quadrant of a horizontal circle which just touches their crowns [188 C].

Such a pendentive is, in fact, a small segment of a much larger dome, of which the diameter is equal to the diagonal of the square base, and which is struck from the level of the top of the piers from which the arches spring. This dome is cut into by the planes represented by the inner faces of the four main arches, and the upper part of it is cut off by the plane representing the springing level of the dome; the four portions remaining are the pendentives, each having the general form of a triangle standing apparently on its apex, but having a solid bearing on the pier and at higher levels on the backs of the great arches.

The four pendentives together fill up the angles, and provide a complete circular base on which the dome itself may rest, and its weight is carried by the four main arches by means of the pendentives, though it bears directly on them, only at the crown of each, where the plane of the circular dome touches that of the square base formed by the main arches.

page 3047

### GUN AND AMMUNITION DEALERS

The business of a gun and ammunition dealer is one that stands alone in large towns and cities, but the tendency of the trade is towards the man who prosecutes this department merely as a side line. It is particularly suitable for exploitation by ironmongers, and, indeed, about three-quarters of the guns and ammunition sold in Great Britain reach users through the intermediary of the ironmongery trade. For this reason, our consideration of the department will be upon the supposition that an established retailer wishes to embark in the selling of guns and ammunition, and is willing to spend £100 upon stock.

**Personal Qualities.** Customers are drawn from the ranks of sportsmen, and success is most promising to the man who is himself a sportsman. In such a position the shopkeeper meets his customers on common ground. His advice is asked and often taken, also he can usually sell better goods bearing higher specific profits if he be himself a good shot.

**Guns.** The chief disbursement of the £100 allocated for stock would be for guns. We suggest the following as a wise opening selection :

|   |    |    |    |
|---|----|----|----|
| Cheap Belgian guns, 12-bore double-bar-           | £  | s. | d. |
| rel hammer guns, say two of each at               |    |    |    |
| 25s., 30s., 40s., 50s. . . . .                    | 14 | 10 | 0  |
| 1 Belgian plain hammerless . . . . .              | 4  | 0  | 0  |
| American single barrel ejector, 2 at 20s. . . . . | 2  | 0  | 0  |
| 2 cheap hammer English d.b. guns at               |    |    |    |
| 50s. . . . .                                      | 5  | 0  | 0  |
| 2 plain hammerless at £5 . . . . .                | 10 | 0  | 0  |

Guns of English manufacture should be stocked only when "nitro-proved." The slight extra cost means an increased selling price, and the policy is all in the direction of safety.

A small stock of air-guns, chiefly for winter trade, is also desirable. These air-guns would cost from 27s. 6d. per dozen for the Daisy to 10s. 6d. each for the Gem; and, while they can be easily procured at short notice, a small stock of 1 dozen Daisy, 1 small Gem, 1 ordinary Gem, costs about £2; with, say, 10,000 slugs, at 6d. per 1,000, and 6 dozen darts at 4s. 6d. per gross, demanding 7s. 3d. more.

In stocking any of the more expensive air-guns, care should be taken to stock them only in the No. 1 size, and, of course, only stock the slugs and darts in that size.

The Daisy air-gun takes only one size, which is the B.B. shot, although it takes equally the No. 1 darts. B.B. shot is sold in boxes of 1,000, at 4d. per box of 1,000.

**Revolvers.** Revolvers should not be handled, except when ordered, because of the

restrictions imposed by the provisions of the Pistols Bill, which requires all vendors of revolvers to see that the buyer is either (a) a gun-licence holder, who must produce the licence for inspection, or (b) a householder who wants to use the revolver in his house or curtilage thereof.

A book has to be kept showing the sale of each revolver, with the name of buyer, particulars of his gun-licence, or proof that he is a householder, and such book can be inspected at any time by the authorities.

Before the passage of the Pistols Bill, a good trade was done in all classes of revolvers, which is now practically closed, because of the restrictions thus imposed. The only revolvers which should be entertained at all are the more expensive ones, because they are more likely to appeal to the class of people who are allowed to buy them; but for a country dealer the stocking of these goods should be eschewed.

**Cartridges.** If a dealer order 25,000 cartridges, he can have his name printed on them and thus get the benefit of the advertisement. He need not take these in one lot; in fact, it would be wiser to take them in two or three lots. These, if loaded in the cheap English unlined case with manufacturer's smokeless powder, would cost him 60s. per 1,000; and if loaded in a metal-lined case, 70s. per 1,000. The purchase of the first instalment of this parcel would absorb £30 to £35.

During the fruiting season quite a demand arises in the fruit districts for a cheap cartridge for bird scaring, and these are generally loaded with a small charge of black powder and shot, and would cost 40s. per 1,000. The charge of shot principally used is No. 8. There is also a demand for a cheap black powder cartridge for rabbits, which could be procured for 50s. per 1,000. This would reduce the £100 by another £7.

All cartridges kept for stock should be 12 bore C.F., as this is the almost universal demand, and should be loaded with 5 and 6 shot, except the bird-scaring cartridges aforementioned. The odd bores of 16, 20, 24, 28, and 410, as well as pin-fires and odd sizes of shot, should be avoided, as the demand is so small that they would not pay to stock and could be supplied from the manufacturers at short notice.

**Miniature Rifles.** With the present demand for miniature rifle shooting, and with clubs springing up in every district, a certain sum should be allocated for the purchase of materials to fill this demand. Miniature rifles can be bought by the trade at all prices from 8s. to 52s. 6d. each to take the 22 ammunition.

Ammunition for this is also to be considered, and the cost of same is : 22 short loaded black powder, 8s. per 1,000 ; 22 short loaded smokeless powder, 10s. per 1,000 ; 22 long loaded black powder, 10s. per 1,000 ; 22 long loaded smokeless powder, 11s. 6d. per 1,000. If purchased in case lots of 10,000, a reduction of 3d. per 1,000 is allowed. This ammunition is the best because of its low price, and is now universally adopted with miniature rifle clubs.

**Accessories.** There are, of course, certain small oddments, which are the necessary appendages of the trade, such as cardboard targets, which can be procured, according to size, from 2s. to 6s. per 1,000. Cleaning rods for guns and rifles are quite inexpensive—thus a 12 bore wooden cleaning rod would cost 1s. 6d. each, and a steel rod for the 22 rifle 8d. each.

Such items as gun-cases, cartridge-bags, etc., should not be stocked at first, because they damage or soil easily, and the demand is a small one. All manufacturers have special illustrated lists of these, and they could be sold from such lists without risk.

**Precaution for Stockkeeping.** Be sure and see that all guns are kept well oiled, and, in the case of rifles and double-barrel guns, are corked at the muzzle. Dirt and grit of any shop can very materially damage the rifling of the barrels or the mechanism of the guns, thus impairing the accuracy and selling value of the rifle, besides running the risk of the damp atmosphere causing rust. Guns once allowed to get rusty lose very materially in their selling value.

Cartridges should be kept in a dry place, free from suspicion of moisture on the one hand, and not overheated on the other. With cartridges which are made of paper tubes, damp tends to swell the tubes and to prevent their entrance into the chamber, and it also detrimentally affects the shooting power of the cartridge. On the other hand, a heated atmosphere tends to develop unduly the violence of nitro powders, and should be avoided.

When displaying guns—and this is the best means of selling them—they should be placed in racks open to view. A very cheap rack can be made with holes cut out to pass the barrels through, the stock resting upon a shelf placed for the purpose.

**Testing Range.** It is always a very serviceable adjunct to the sale of guns and ammunition if facilities can be afforded whereby the customer can test his purchases on the premises. The providing of these facilities is rather expensive, and can be undertaken only if the trade warrant it. As far as miniature rifles are concerned, the installation is cheap enough. A small target to stand the impact of a 22 cartridge can be got for £2, and may be placed in the back yard. The effective range of most miniature clubs for indoor ranges is 25 yards, but a good illustration could be made of the efficacy of the rifles, etc., on a 10 yards range.

**Shooting Gallery.** It often pays to install a shooting range where the general public can test and exhibit their skill in marksmanship

in return for a humble coin for every attempt. The present time, when endeavours are being made to develop the individual shooting ability of our citizens, is suitable for establishing such ventures, which need be open, say, only in the evenings, and perhaps during holidays. The gallery ought to have targets at 25 yards, but if there be no near competition in the business, a 10 yards range may serve. Half a dozen rifles for service in the gallery may cost anything from 7s. to 84s. each. It is well to give not less than £3 for each, as good weapons may be had at the price, and these will attract good marksmen. The gallery ammunition costs 8s. per 1,000 upwards, but we may allow 20s. for good charges. At a penny each, 1,000 shots yield in gross revenue the sum of 83s. 4d., surely a high enough rate of profit to satisfy the most grasping of retailers. Some galleries charge only a halfpenny per shot, and there is good return for the venture even at this price.

**Prices.** The question of price maintenance on cartridges is now being threshed out, and it is very likely that 1907 will see some practical results. A satisfactory arrangement was almost reached in the early part of the present year (1906), but fell through because of the action of one of the manufacturers. It is now, however, in course of settlement. This price maintenance is based upon the giving of 25 per cent. profit on selling prices to all dealers in cartridges.

Guns pay well. The list prices of makers and wholesale importers are frequently subject to 50 per cent. trade discount, and occasionally list prices can be secured. Competition or other reasons usually cause a lower rate of profit to be adopted, but prices are seldom lower than a basis which allows a profit of 33½ per cent. from selling prices.

The new terms now given by all ammunition manufacturers embrace a special discount for prompt cash, which works out on an order of 25,000 cartridges to a percentage of 10 per cent. on the year, and this 10 per cent., besides meaning an additional profit on his trade, enables him to compete more successfully with his rivals, and also ensures him the good graces of the firm with whom he is doing business.

We have dealt in this article with loaded cartridges because the restrictions now imposed by the Home Office make the loading of cartridges by the shopkeeper inexpedient, and by buying his components he can seldom make up his cartridge at the price of the fully loaded article filled by the manufacturer.

**The Explosives Act.** It is desirable that the retailer of gunpowder and explosives should make himself familiar with the obligations imposed by the Explosives Act. There are to-day many retailers of experience and standing who are infringing the provisions of the Act through ignorance or misconception. The original Act has been loaded with Orders in Council until it is rather difficult to decide what is exact law upon several points, but at least the following provisions should be observed. The law differentiates between gunpowder and nitro compounds. The

former is a compound made of saltpetre, charcoal, and sulphur. A person wishing to keep gunpowder for sale must register his name, trade, and premises with the local authority, paying a registration fee not exceeding 1s.

This registration entitles the person registered to keep gunpowder by three methods:

1. In a specially constructed detached building or a fireproof safe away from any dwelling-house or thoroughfare. Maximum quantity which may be stored is 200 lb.
2. In a fireproof safe in a shop or dwelling. Maximum quantity, 100 lb.
3. In a box or receptacle capable of being closed so as to prevent access by unauthorised persons. This box or receptacle may be in any shop or dwelling, and may contain up to 50 lb. of gunpowder.

Common blasting powder may be kept under an ordinary gunpowder licence, as its storage is governed by the conditions which pertain to gunpowder. The stock may consist of both common blasting powder and gunpowder if the total quantity does not exceed that allowed by the Act. Safety fuses cannot be kept in addition to gunpowder or blasting powder upon premises registered only for the storage of gunpowder, but safety fuses only may be kept to any amount without registration.

**Mixed Explosives.** All explosives other than gunpowder and blasting powder are, under the Act, "mixed explosives." The group includes Amberite, E.C., Schultze, Kynoch Smokeless, Canonite Sporting Ballistite, Walsrode, Empire, Diamond Smokeless—and these may not be stored as gunpowder, whether in bulk or in cartridges. In order to hold stock of these, the retailer must be registered for the sale of "mixed explosives," which he must keep in either of two specified manners. He may use a "substantial" receptacle which may be a safe or a strong box of wood or iron furnished with a lock and key to prevent access by unauthorised persons. But safety cartridges and percussion caps must not be kept in the same receptacle as gunpowder or small arms nitro compounds; they may be kept if separated by a suitable partition, or in another part of the same room, or in another room of the same registered premises. Under these restrictions, the dealer may keep up to 50 lb. of gunpowder and small arms nitro compounds, and a quantity not exceeding 500 lb. of explosive contained in safety cartridges, safety fuses, and percussion caps. Safety fuses may be kept with any other explosive. Detonators and fireworks must be kept apart from each other and from all other explosives.

Should the dealer desire to hold stock of a larger quantity than permitted under the conditions stated, he may provide a special building of stone, brick, concrete, or iron, detached from any dwelling house, and at a safe distance from any public highway, or a strong fireproof safe similarly placed, and in this manner he may store up to 200 lb. of gunpowder and small arms nitro compounds, in addition to not more than 500 lb. of explosives contained in safety cartridges, safety fuses, and percussion caps.

**Loading Cartridges.** Should the dealer find that his stock of gunpowder and small arms nitro compounds is in excess of that permitted by the Act, he may avoid infringement by converting the excess into safety cartridges. The regulations laid down by the Gunmakers' Association of London should be observed, as they embrace all legal obligations. They are as follow:

In every case where a loading room is to be used, notice to that effect must be given to the local authorities on the form which is lodged for registering the premises.

Under no conditions shall more than 5 lb. of powder or small arms nitro compounds be present in the loading room at one time, and then only if such explosive is to be immediately used for filling cartridges, powder loaded into wadded cartridge-cases not being counted.

The loading room should be as far as possible isolated from all risk of fire or explosion. The floor should be covered with linoleum or other unbroken surface, and in no case should bare boards be exposed, as the joints are liable to harbour spilt grains of powder. There should be no exposed iron on the floor, bench, shelves, or walls, such as iron nail-heads, etc.

No fire is allowed to be in the room while any filling of cartridges is going on, and no artificial light unless it is so screened and placed as not to cause any danger by fire or explosion.

Every precaution should be taken to prevent the introduction into the loading room of grit or dirt, and, with this end in view, the employees should wear, when in the loading room, over their ordinary boots magazine boots or goshies, or else their ordinary boots should be removed; and they should, where possible, also be provided with such outside clothing or aprons as will effectually cover the ordinary clothes.

The strictest precautions must be taken to prevent the introduction of matches into the loading room.

No work unconnected with the manufacture of cartridges shall be carried on at the same time as the filling of cartridges.

## HABERDASHERS

Haberdashery on its retail side is seldom a distinct independent business, but it is a feature of the scheme of this course that consideration should be given to departments. Haberdashery is usually included in the drapery and a few of its allied trades which are studied in other articles. But it is suitable for exploitation as a separate trade by, say, a draper who is advanced in life, and who finds himself out of employment at an age when he cannot get another. We know several men who have done much better for themselves by such a venture than they could have done by taking another situation even had they been able to find one.

Haberdashery comprises all manner of "small wares" connected with the making of garments—needles, pins, bodkins, cottons, tapes, and such things—which are in everyday demand everywhere. The trade or the department is commonly considered a paltry one, as nearly everything sold is of low price; but it requires, perhaps for that reason, greater attention to detail if it is to be successful. The bump of orderliness must be well developed in the haberdasher, else the multitude of small articles of which his stock is composed will become hopelessly confused, and render the prompt service of customers impossible.

Ammunition for this is also to be considered, and the cost of same is : 22 short loaded black powder, 8s. per 1,000 ; 22 short loaded smokeless powder, 10s. per 1,000 ; 22 long loaded black powder, 10s. per 1,000 ; 22 long loaded smokeless powder, 11s. 6d. per 1,000. If purchased in case lots of 10,000, a reduction of 3d. per 1,000 is allowed. This ammunition is the best because of its low price, and is now universally adopted with miniature rifle clubs.

**Accessories.** There are, of course, certain small oddments, which are the necessary appendages of the trade, such as cardboard targets, which can be procured, according to size, from 2s. to 6s. per 1,000. Cleaning rods for guns and rifles are quite inexpensive—thus a 12 bore wooden cleaning rod would cost 1s. 6d. each, and a steel rod for the 22 rifle 8d. each.

Such items as gun-cases, cartridge-bags, etc., should not be stocked at first, because they damage or soil easily, and the demand is a small one. All manufacturers have special illustrated lists of these, and they could be sold from such lists without risk.

**Precaution for Stockkeeping.** Be sure and see that all guns are kept well oiled, and, in the case of rifles and double-barrel guns, are corked at the muzzle. Dirt and grit of any shop can very materially damage the rifling of the barrels or the mechanism of the guns, thus impairing the accuracy and selling value of the rifle, besides running the risk of the damp atmosphere causing rust. Guns once allowed to get rusty lose very materially in their selling value.

Cartridges should be kept in a dry place, free from suspicion of moisture on the one hand, and not overheated on the other. With cartridges which are made of paper tubes, damp tends to swell the tubes and to prevent their entrance into the chamber, and it also detrimentally affects the shooting power of the cartridge. On the other hand, a heated atmosphere tends to develop unduly the violence of nitro powders, and should be avoided.

When displaying guns—and this is the best means of selling them—they should be placed in racks open to view. A very cheap rack can be made with holes cut out to pass the barrels through, the stock resting upon a shelf placed for the purpose.

**Testing Range.** It is always a very serviceable adjunct to the sale of guns and ammunition if facilities can be afforded whereby the customer can test his purchases on the premises. The providing of these facilities is rather expensive, and can be undertaken only if the trade warrant it. As far as miniature rifles are concerned, the installation is cheap enough. A small target to stand the impact of a 22 cartridge can be got for £2, and may be placed in the back yard. The effective range of most miniature clubs for indoor ranges is 25 yards, but a good illustration could be made of the efficacy of the rifles, etc., on a 10 yards range.

**Shooting Gallery.** It often pays to install a shooting range where the general public can test and exhibit their skill in marksmanship

in return for a humble coin for every attempt. The present time, when endeavours are being made to develop the individual shooting ability of our citizens, is suitable for establishing such ventures, which need be open, say, only in the evenings, and perhaps during holidays. The gallery ought to have targets at 25 yards, but if there be no near competition in the business, a 10 yards range may serve. It is well to give not less than £3 for each, as good weapons may be had at the price, and these will attract good marksmen. The gallery ammunition costs 8s. per 1,000 upwards, but we may allow 20s. for good charges. At a penny each, 1,000 shots yield in gross revenue the sum of 83s. 4d., surely a high enough rate of profit to satisfy the most grasping of retailers. Some galleries charge only a halfpenny per shot, and there is good return for the venture even at this price.

**Prices.** The question of price maintenance on cartridges is now being threshed out, and it is very likely that 1907 will see some practical results. A satisfactory arrangement was almost reached in the early part of the present year (1906), but fell through because of the action of one of the manufacturers. It is now, however, in course of settlement. This price maintenance is based upon the giving of 25 per cent. profit on selling prices to all dealers in cartridges.

Guns pay well. The list prices of makers and wholesale importers are frequently subject to 50 per cent. trade discount, and occasionally list prices can be secured. Competition or other reasons usually cause a lower rate of profit to be adopted, but prices are seldom lower than a basis which allows a profit of 33½ per cent. from selling prices.

The new terms now given by all ammunition manufacturers embrace a special discount for prompt cash, which works out on an order of 25,000 cartridges to a percentage of 10 per cent. on the year, and this 10 per cent., besides meaning an additional profit on his trade, enables him to compete more successfully with his rivals, and also ensures him the good graces of the firm with whom he is doing business.

We have dealt in this article with loaded cartridges because the restrictions now imposed by the Home Office make the loading of cartridges by the shopkeeper inexpedient, and by buying his components he can seldom make up his cartridge at the price of the fully loaded article filed by the manufacturer.

**The Explosives Act.** It is desirable that the retailer of gunpowder and explosives should make himself familiar with the obligations imposed by the Explosives Act. There are to-day many retailers of experience and standing who are infringing the provisions of the Act through ignorance or misconception. The original Act has been loaded with Orders in Council until it is rather difficult to decide what is exact law upon several points, but at least the following provisions should be observed. The law differentiates between gunpowder and nitro compounds. The

former is a compound made of saltpetre, charcoal, and sulphur. A person wishing to keep gunpowder for sale must register his name, trade, and premises with the local authority, paying a registration fee not exceeding 1s.

This registration entitles the person registered to keep gunpowder by three methods:

1. In a specially constructed detached building or a fireproof safe away from any dwelling-house or thoroughfare. Maximum quantity which may be stored is 200 lb.

2. In a fireproof safe in a shop or dwelling. Maximum quantity, 100 lb.

3. In a box or receptacle capable of being closed so as to prevent access by unauthorised persons. This box or receptacle may be in any shop or dwelling, and may contain up to 50 lb. of gunpowder.

Common blasting powder may be kept under an ordinary gunpowder licence, as its storage is governed by the conditions which pertain to gunpowder. The stock may consist of both common blasting powder and gunpowder if the total quantity does not exceed that allowed by the Act. Safety fuses cannot be kept in addition to gunpowder or blasting powder upon premises registered only for the storage of gunpowder, but safety fuses only may be kept to any amount without registration.

**Mixed Explosives.** All explosives other than gunpowder and blasting powder are, under the Act, "mixed explosives." The group includes Amberite, E.C., Schultze, Kynoch Smokeless, Canonite Sporting Ballistite, Walsrode, Empire, Diamond Smokeless—and these may not be stored as gunpowder, whether in bulk or in cartridges. In order to hold stock of these, the retailer must be registered for the sale of "mixed explosives," which he must keep in either of two specified manners. He may use a "substantial" receptacle which may be a safe or a strong box of wood or iron furnished with a lock and key to prevent access by unauthorised persons. But safety cartridges and percussion caps must not be kept in the same receptacle as gunpowder or small arms nitro compounds; they may be kept if separated by a suitable partition, or in another part of the same room, or in another room of the same registered premises. Under these restrictions, the dealer may keep up to 50 lb. of gunpowder and small arms nitro compounds, and a quantity not exceeding 500 lb. of explosive contained in safety cartridges, safety fuses, and percussion caps. Safety fuses may be kept with any other explosive. Detonators and fireworks must be kept apart from each other and from all other explosives.

Should the dealer desire to hold stock of a larger quantity than permitted under the conditions stated, he may provide a special building of stone, brick, concrete, or iron, detached from any dwelling house, and at a safe distance from any public highway, or a strong fireproof safe similarly placed, and in this manner he may store up to 200 lb. of gunpowder and small arms nitro compounds, in addition to not more than 500 lb. of explosives contained in safety cartridges, safety fuses, and percussion caps.

**Loading Cartridges.** Should the dealer find that his stock of gunpowder and small arms nitro compounds is in excess of that permitted by the Act, he may avoid infringement by converting the excess into safety cartridges. The regulations laid down by the Gunmakers' Association of London should be observed, as they embrace all legal obligations. They are as follow:

In every case where a loading room is to be used, notice to that effect must be given to the local authorities on the form which is lodged for registering the premises.

Under no conditions shall more than 5 lb. of powder or small arms nitro compounds be present in the loading room at one time, and then only if such explosive is to be immediately used for filling cartridges, powder loaded into wadded cartridge-cases not being counted.

The loading room should be as far as possible isolated from all risk of fire or explosion. The floor should be covered with linoleum or other unbroken surface, and in no case should bare boards be exposed, as the joints are liable to harbour spilt grains of powder. There should be no exposed iron on the floor, bench, shelves, or walls, such as iron nail-heads, etc.

No fire is allowed to be in the room while any filling of cartridges is going on, and no artificial light unless it is so screened and placed as not to cause any danger by fire or explosion.

Every precaution should be taken to prevent the introduction into the loading room of grit or dirt, and, with this end in view, the employees should wear, when in the loading room, over their ordinary boots magazine boots or goshes, or else their ordinary boots should be removed; and they should, where possible, also be provided with such outside clothing or aprons as will effectually cover the ordinary clothes.

The strictest precautions must be taken to prevent the introduction of matches into the loading room.

No work unconnected with the manufacture of cartridges shall be carried on at the same time as the filling of cartridges.

## HABERDASHERS

Haberdashery on its retail side is seldom a distinct independent business, but it is a feature of the scheme of this course that consideration should be given to departments. Haberdashery is usually included in the drapery and a few of its allied trades which are studied in other articles. But it is suitable for exploitation as a separate trade by, say, a draper who is advanced in life, and who finds himself out of employment at an age when he cannot get another. We know several men who have done much better for themselves by such a venture than they could have done by taking another situation even had they been able to find one.

Haberdashery comprises all manner of "small wares" connected with the making of garments—needles, pins, bodkins, cottons, tapes, and such things—which are in everyday demand everywhere. The trade or the department is commonly considered a paltry one, as nearly everything sold is of low price; but it requires, perhaps for that reason, greater attention to detail if it is to be successful. The bump of orderliness must be well developed in the haberdasher, else the multitude of small articles of which his stock is composed will become hopelessly confused, and render the prompt service of customers impossible.

**The Shop.** The haberdasher's shop need not—indeed, must not—be in the main thoroughfare, where the rents are very high, else the expense will swallow up the capital in a very short time. As the goods are not bulky, the premises may be small, and should be rented at not more than £40 in a London suburb or £20 in one of the smaller provincial towns. The fittings are for use more than for show, and are inexpensive—a counter (with glass case top if possible), a few nests of drawers, with plenty of trays, divisions, and partitions. The shelves may be put up by the man himself if he can use tools intelligently. No expensive or elaborate window fittings are needed. The goods must be neatly displayed and classed together, but need not be priced. In fact, the sum of £10 spent in preparing the shop for the stock should be sufficient.

**Capital and Stock.** An adequate stock of haberdashery can be purchased for £50. A "connection" trade must be the object in view, and a well-assorted stock is necessary. Goods that fade quickly or that are of a fancy nature should be avoided as much as possible. There are some standard articles which form the backbone of the trade, and these must be purchased in every variety likely to be demanded. There are some trades in which selling from catalogues is possible, but that we are now considering is not one of them. For instance, needles of every size and variety for both hand-sewing and machine use must be kept, also pins in all their various forms, from the big blanket pin to the small "baby" variety, safety pins, black and white pins, steel pins, jet-headed pins, large fancy hat-pins, and as for hairpins—the name of the different kinds is legion.

In sewing cottons all the good makers must be represented, as customers have their special fancies. Then there are knitting and crochet cottons, mending cottons, and wools in hanks and on cards, threads in black, white, and colours, from the fine to the heavy qualities; thread for carpets and upholstery work, machine and sewing silks of all colours, and twist for buttonholes. The variety of tapes is also large, including white, black, and coloured in all widths both linen and cotton, bindings, beltings, strappings, galloons, webs, cords, dress preservers, and boot and stay laces in silk and cotton.

Dressmakers' sundries will include hooks and eyes, whalebone, springs for dresses, and corset busks. There must be tape measures from the humble penny article to the aristocratic shilling spring measure in a metal case, thimbles in steel, bone, brass, and silver; buckles, waddings in black, white, and colours—the last-named for jewellers' use—cords, elastics, garters, suspenders, glove and boot button-hooks. There is great variety in buttons, which must be kept in linen, cloth, china, pearl, metal, bone, and horn for every possible kind of garment in all colours and styles. We have enumerated the classes of haberdashery which may be bought for the £50 note we assumed to be at the disposal

of the opening shopkeeper. These may be considered the essentials of the stock.

**Side Lines.** There are other things which should be added at the beginning, if funds permit. The list of extras includes trimmings and gimps for ladies' dresses and mantles, girdles, buckles and clasps, belts, braids, fringes, black and coloured beads, jet trimmings, useful yarns, such as Scotch yarns, Berlin and Shetland wool, Andalusian fingering. Tailors' trimmings should also be included as soon as possible. They will comprise cotton, silk, and wool linings, Italian cloth, buckram, buttons, twists, chalk, and all the little accessories needed by the tailor.

By studying to make the stock complete and to avoid the likelihood of being asked for anything which he cannot supply, the haberdasher will acquire the reputation of keeping "the handy shop," and he will be resorted to as a matter of course, with the confidence that he will be able to supply at once what is wanted.

Yet there are a few things which it will be well to avoid keeping—coloured ribbons, for instance, which involve a heavy outlay and result in loss by soiling unless their sale be very large.

Certain articles of cutlery pertinent to the haberdashery trade are worth keeping, as they are exceptionally remunerative—scissors for embroidery, buttonholes, and for dressmakers' and household use, tailors' shears, pocket knives, stilettos, and nail-files.

#### **Sewing Machines and Fancy Goods.**

A sewing machine might be bought and held for sale. The class of customers who come to the counter are those who use sewing machines, and an odd machine can be sold now and again. The profit on each machine need never be less than a sovereign. If the sewing machine trade be attempted, there will be a demand to sell the machines on the instalment system; but, unless the retailer knows the customer to be absolutely exact in meeting obligations, he will resist blandishments to induce him to part with goods on such terms.

Some fancy goods offer opportunities, especially about Christmas time—such things as needle and cotton cases, cabinets of haberdashery assortments in wood and leather, to sell at from 1s. to 10s. 6d., ladies' companions, and not forgetting the "bachelor's roll" containing an assortment of buttons and thread, needles and pins, and selling at about 2s.

**Profits.** The profits will not be less than 20 per cent. of the selling price, and on fancy articles such as scissors, thimbles, needle-cases, not less than 33½ per cent. Most of the selling will be for cash, as the money is taken in small amounts; but it will be well to have a few monthly accounts with tailors and dressmakers, who will probably appreciate the convenience by becoming steady and regular customers. As the goods of a haberdasher do not get out of fashion or soil easily, there is practically no loss from unsaleable or soiled stock such as is found in the general drapery trade.

By W. S. MURPHY

THANKS to the great art spirits of the nineteenth century, the textile designer has been freed from the bonds of convention. Our designs are not now the futile imitations of foreign forms, made conventional beyond recognition, which were imposed upon our predecessors of the early Victorian era. The designer may go out into the fields, and, in loving communion with Nature, derive fresh ideas and new forms. He can bring from the roadside the beauty of familiar flowers; from the harvest field the golden tresses of the barley, the rich fulness of the wheat, the waving crown of the ripened oat; from the woodland visions of green and tinted traceries against the shadowy verdure of the grass or the azure light of the sky. These, his treasures, he can freely display on the cloth designs he makes for the weaver and the wearer. Allowing free play to his imagination, he must also discipline it with the sense of fitness.

The latitude given to the cloth designer may be nobly used or grossly abused. There are two directions which wrong practice has taken. One is the sacrifice of sound structure to ornament; the other is a false sensationalism, presenting objects with a pretence at reality altogether false and grossly vulgar. We can confidently say, however, that at no time in the history of British industry was there so much good art and sound design in textiles as there is at the present day.

**Ground Warp and Weft Figures.** Making figures is so easy that we feel tempted to enter lightly on the venture. Take a plain cloth, for example. What is easier than to make the weft skip over the warp here and there, or in regular gradation, to form a design or figure on the surface of the cloth? It is easy, very easy, and we would doubtless produce very pretty figures; but the result would perhaps astonish us sorely. At the end of a yard we might find our warp pulled tight here and lying slack there, and the figures all staggering drunkenly across the cloth. Inquiring into the causes, we would find that the very foundation principles of textile production had been violated. Structure is the alpha and omega of weaving. We observed how every pick of weft in plain cloth takes up a certain length of warp. If any warp thread is missed by the weft, it must become slack, because what it gives out with the rest is not taken up. When one warp and one weft are used, the balance must be maintained in some way. If, at this point, the weft

floats over seven warp threads at this pick, six of the same section next pick, four at the next, the slackness on the four of the missed three picks, and on the other two of the picks missed, must be made up in another place, or the balance of the web is destroyed. We may repeat all over the fabric, at close intervals, the small figure, and so restore the balance before any harm is done; but while the relation of warp and weft may thus be put right, the pattern may present a very broken and absurd appearance. We can say, however, that a simple and modest design, which is worked in accordance with what may be called the law of textile structure, is always more pleasing to the eye than any form of pattern which does not come within the law.

**Practical Rules.** In general, the designer should lay down a plan of the proposed figure, or combination of figures, and find out what intersection of warp and weft is needed to form the pattern. When this has been done, the practicability, or otherwise, of the design will at once appear.

Common twills and broken or satin twills are often ornamented with good effect. In fact, the comparative looseness of the fabric lends itself to aid in the formation of figures. Selected with judgment, very slight changes on the twills produce fine effects, especially in forming natural figures in conventionalised forms, definitely suggesting without attempting too much.

Using the ground warp or weft, or both, it is possible to make figured cloths of a highly artistic and useful character. Small mathematical figures, spots, stripes, checks, floral designs, scrolls and flourishes can be carried out on the material of the fabric. One limit applies to all designs, if the fabric is not purely ornamental — the design must not occupy so many threads as to weaken the body of the cloth.

**Diaper and Damask.** Those fine fabrics are figured on a simple principle, the explanation of which need not take long, though the practical working of the designs should be carefully considered. Diapers are simple twills [136], the pattern being formed by the change from warp to weft on either surface. Suppose it is desired to form a four-end twill on an eight-end pattern. On the first eight ends the weft comes to the surface; on the second eight ends the warp forms the twill. It is as if we had turned over the web, bringing the back to the front in a magical fashion. The twill runs the opposite way when formed by the warp from that when formed by the weft. The simple change in the direction of the twill,

added to the different direction of the predominating threads, alters the aspect of the pattern to such a degree that the average unskilled observer would refuse to accept the statement that the two squares are merely reversals of one twill. Working on this principle, we can produce a large variety of patterns.

**Styles of Diapers.** On the diapers of the middle of the nineteenth century the figures are mostly on the mathematical plan; but during the past twenty years the difference between diapers and damasks has almost disappeared. It used to be said that a true diaper was in squares or sections of squares, and damask was floral or figured; but now you will find more diapers in floral designs than any other form of pattern. Instead of a simple twill, therefore, we have often a satin or broken twill, this form of twill obviously lending itself more readily to the formation of

large and varied figures. By making the figures with a simple change from weft to warp on the surface, we avoid one danger of figuring with single warp and weft, *viz.*, the weakening of the fabric by the predominance of floating threads. The other trouble which arises from the irregular interweaving of warp and weft

is never wholly overcome, however, except in specially happy combinations. Fine fabrics do not show the defect so obviously as heavy cloths; but close examination reveals the fact that the interweaving at the point of change is imperfectly covered.

**Extra Warps and Wefts.** Advancing from the simple to the complex, we now come to consider a class of fabrics which it is the ambition of every young designer to handle. Long before we have mastered the rudiments of cloth structure, we dream of the varied and rich patterns we could make if only we had liberty to work with extra yarns. In its proper place, such an ambition is far from reprehensible; its proper place, however, is dreamland for a year or two. Excepting in special forms, which must be studied in detail, the principle of making double-faced cloths is applied to the use of extra yarns for figuring and ornament. Sometimes we use only extra warp, sometimes only extra weft, and in some instances added warp and weft. In a large number of those

cloths, the extra yarn plays no part in the structure of the cloth. The sole concern of the designer, in such cases, is to obtain a proper passage for his extra material, and a strong binding. These two things are not always easily obtained, especially if the intervals between the figures formed by the extra yarn is considerable. Where it is possible to use soft, thick threads, the difficulty of getting a clear passage is evaded, but the problem of safe binding is rather intensified.

**Binding Figures.** If the ground cloth be light, we cannot carry the thick threads of the figuring yarns along with it; and if we cut, we have little beyond the binding threads at the points of intersection to hold the yarn. This is not sufficient, in most cases, and some other plan is generally adopted, such as using the binding edge as shading of the figure, or some other expedient of a like

nature to give the figuring yarn a hold in the structure of the cloth. With liberty to use as many colours as we need, and to pile, say, three or four yarns on top of each other, should the design so require, we enter on the freedom of the artist. But warp and weft impose limitations which can be evaded only by the art which conceals art. Stripes, spots, checks,

137. SWIVEL CLOTH

rows of figures, straight lines of flower or foliage, curves that give a regular gradation of intersection between the woven threads, should be attempted first. An exacting market makes higher and ever higher demands upon the designer's craft and ingenuity; but it is only after we have thoroughly mastered the simpler forms of design that we can hope successfully to venture on those combinations which bring weaving up to the level of the plastic arts. Learn to use extra warp, extra weft, then both; next combine the ground with the extra yarns, and, having done all this, the higher possibilities of textile design will be well within reach.

**Swivels.** Without a knowledge of the structure of the loom, this class of design can hardly be fully understood; but we must presuppose a certain general understanding of the weaving machine, and in a short time expect to study the loom in every detail. We have judged it better to develop our theories before considering the applications of them, which are many. In weaving cloth we have the warp and

the shuttle, the latter bearing the weft into the warp and crossing from side to side. The swivel is an apparatus holding as many small shuttles as there are figures in the breadth of the web, the weft from each shuttle forming only one figure [137]. This is a method of forming figures with extra weft, which is coming more and more into use. The crossing shuttle waits, and the warp is held while the little shuttles perform their work. By this device weft is saved, and there is no need to cut away the floating threads between one figure and another. Anxiety as to binding is also spared. Many highly ingenious applications of the swivel have been invented, but the secrets of these are jealously guarded by the firms using them. Many patterns which seem textile impossibilities are done by the swivel.

**Lappets.** Employed for a similar purpose, lappet weaving is the opposite of swivel weaving. Instead of extra weft we have, in lappet, extra warp, used in a peculiar way. This extra warp may come from a second beam, or a creel of cops set below the loom. The threads are led through needles set upright on a horizontal bar which has two movements. It moves up so as to bring the threads it carries to the level of the warp as the shuttle brings the weft across; and it moves to and fro in obedience to the guiding finger inserted in a wooden dial at the side of the loom. The first movement is to get the benefit of the binding weft; the second movement is to form the figure on the warp, the curves on the dial being turned in the manner necessary for the formation of the figure [138]. As the lappet apparatus moves on the under side of the warp, the web is woven wrong side up. The dial being movable, the positions of the lappet threads may be altered in any way the designer desires. This enables him to avoid the stiffness of line and straight regularity which are the great obstacles to artistic textile work. Lappet weaving has its obvious limits; the threads must always present a flat surface, which tends to give a conventional appearance to the figures. But the variety of colour and figure this method of weaving affords makes it worthy of keen study and frequent application.

**Various Fancy Cloths.** The old hand-loom weavers were probably as intelligent a class of craftsmen as the world has known. Even before the power loom was invented, the weaver had made his machine an instrument

capable of performing operations far more complex than the mere plaiting of warp with weft. As a result, forms of cloth have been handed down to us which call for both ingenuity and artistic skill. In our present course we can glance at but a few of the various fancy cloths evolved by the weaving craft.

**Crinkled Cloths.** Every now and again there arises a demand for cloths which have a drawn, or crinkled appearance, and the demand is met. If you pull a warp thread out of a piece of cloth, you will observe that it crinkles up; held with moderate firmness, the crinkles form regularly. Apply the principle to weaving. Having determined the measure of crease or crinkle required, and the breadth between one ridge and the next, you fix behind

138. LAPPET CLOTH

the reed of the loom a series of nippers, or catches, which grip on to the selected warp threads. These threads are momentarily held while all the rest go forward with the movement of the loom. The combined slackness and tightness thus created form the cloth into regular crinkles, which are ineradicable and integral in the body of the fabric. The cloth can be no longer than the shortest warp threads, and the warp and weft which have gone forward must curl up to keep alongside the shorter length of the restrained warp. Many very pretty effects are achieved by this simple device.

**Flounces or Tucks.** A common application of the crinkling method is the formation of tucks or flounces by weaving. In this case, however, the cloth is double, and two warps are employed. The double cloth is woven to form the basis of the fabric. At the moment when the tuck is to be woven the one warp is withdrawn, and a single cloth is made the breadth necessary for the tuck. When this has been done, the other warp, which has not moved an inch, comes into play again. The slack is made up by the folding together of the cloth, which is secured by the resumption of the weaving of the whole fabric.

**Fancy Warps and Wefts.** Variations in colour of warp and weft we take as a matter of course; but designers have called into use another device, which, when properly applied, is singularly effective. Fancy forms of yarn, such as knoppes, curled twists, and loop threads, vary the surfaces of cloths without making any special demand upon the loom. It is safer to use these yarns as warp because we have more

certainly of placing them rightly. Cheap forms of imitation astrakhan and other imitation furs can be produced in this way, besides many fancy dress cloths.

**Special Fabrics.** There are some fabrics which owe their existence wholly to the love of mankind for decoration. In southern countries, and during the warm summers of temperate climes, clothing is worn by civilised nations less for physical comfort than for social respectability and the pleasure of wearing fine clothes. Therefore, the weavers very early devised a class of fabrics which combine lightness with strength, and which may be easily ornamented. Among these we find a large range of light cloths, which are technically classed as *gauzes*.

On the other hand, there is a class of cloths which have been from time immemorial dedicated to ceremonial uses, or for giving a rich appearance to the persons by whom they are worn. These are what we call *pile cloths*, including in the class velvets, velveteens, and plushes. Velvet is the stuff of which the regal robes of kings and princes are made : it enters into the structure of the crown of the monarch and the coronets of dukes and peers. Because of its peculiar structure, velvet is the richest of all fabrics, the heaviest, and yet the most easily draped. Composed of short threads of silk standing up from the ground of the cloth, closer and finer than the finest fur, velvet is the costliest and strongest of silk fabrics. It is used for hangings and draperies by persons of wealth, and the designer gets many an opportunity of exercising on velvets his highest artistic powers.

Plush is the cotton imitation of velvet, and serves many useful as well as ornamental purposes. For hangings of a temporary nature, this material serves just as well as velvet. Figured and stamped plush is greatly used in the making of cheap picture frames, the upholstery of furniture, and other purposes of that nature.

Velveteen is also a cotton velvet : but it has a character and position of its own. In structure, as we shall show, the cheaper cloth differs considerably from velvet. It is the true fustian, the cotton cloth which was the favourite wear of millions of the working people during the early part of the nineteenth century, and originally demonstrated that cotton could be made into a strong and substantial cloth. The pile of new velveteen possesses a sheen which rivals in lustre the cheaper classes of silk velvets. It fades soon, of course : but the fabric is undoubtedly very pleasing and of great strength.

**Gauze.** In the fabrics we have already studied, the main structure has been composed by crossing weft and stretched warp ; but when we come to gauze a different stage in textile development is entered. Warp is the passive factor in the formation of plain cloths, but it takes an active part in the construction of gauze. Lappet weaving has prepared the way, in a measure, for the active warp ; but the action of gauze warp is strongly significant, for

all that. The whole loom has become active. To make plain gauze, we divide the warp thread into pairs, and gear, or mount, the loom so that each pair of warp threads will cross, the one over the other, each thread passing from right to left, and up and down alternately [139].

139. SECTION OF GAUZE

taken for granted, of course, that two parallel threads cannot twine round each other ; they can only change positions, and perform half a circle each. Two threads acting on each other in that way would be futile, and produce nothing ; but the coming of the weft thread between them at the moment of crossing makes all the difference. When the crossing thread wants to get back to its former position, it finds the weft between it and the crossed thread, forming a little knot. The next pick of weft comes along and is brought as closely up to its neighbour as possible ; but the thickness of the two warp threads intervenes, and the weft threads must lie apart. This is

140. DIAGRAM OF GAUZE

the essential nature of gauze, it is practically a kind of miniature netting [140]. With a fabric so firmly bound, so strong, and so open in texture, variation and ornament suggest themselves. The first step is to find out how many good and firm gauzes we can produce by varying the crossing of the threads. Reversing the cross of every alternate pair, we obtain a result not unlike a diaper effect ; carrying out the idea further, very pretty figuring may be done by simply altering the orders of crossings. Alternate thick and thin warp or thick and thin weft produce quite admirable effects. Changing the order of weaving, weaving a different number of picks in selected crossings, and other similar and simple devices, give variety to gauzes, and also prettiness at small cost.

**Gauze and Lace.** It has been said, with a certain degree of truth, and an equal measure of severity, that you can do anything with gauze except make it into a good cloth. All the devices of ornament can be utilised on gauze—extra warp, extra weft, swivel, lappet, knopp, and curl yarns, and in addition, we can introduce plain cloth. The highest achievements of the gauze loom have been in the direction of producing elaborate lace fabrics. For a time, the cheap production of the lace looms seemed to drive the gauze weaver out of that market ; but the tide has turned the other way, and the gauze weaver threatens seriously to retaliate upon the rival trade. Lace insertions, narrow laces for trimmings, lace handkerchiefs, table-centres, fancy covers of all kinds, figurings the most delicate, are now produced on the gauze loom. But all this is matter for experiment ; any length of discoursing would not help the student. In such a case, the tutor ought simply to give a few practical hints, show what can be accomplished, and leave the

rest to the intelligence, energy, and practical experiment of the student.

**Lace.** The lace designer has models by the thousand. We speak of the machine-lace designer, of course. From before the Christian era down to the present hour the ingenious minds, vivid fancies and nimble fingers of leisured ladies, religious devotees, and industrious housewives have been constantly developing new forms of lace. Lace designers, therefore, are more often required to find out how to weave a certain pattern than to invent new forms of lace. Bobbin-net is the simplest form of lace, and affords easy lessons for the beginner. He has to regard the warp threads as straight vertical lines, round which the weft threads, which have a limited area of crossing motion, but a constant power of twining from warp thread to warp thread, must be twisted in such order as to form the pattern. Lace warp is vertical, and not horizontal as in the weaving loom. The weft does not shoot across the web, but passes between one pair of warp threads and comes back between another pair at such nearness of distance as may be designed. By this twining the net is formed. In ordinary bobbin-net the warp threads are passive, the bobbins doing all the work. But, suppose we give the warp threads mobility, complicate the actions of the bobbins, and add appliances for directing both warp and weft in special ways, what then? We shall, at any rate, possess a real lace loom, and one capable of being used for the reproduction of very complex designs. It is obvious that with such a machine fabrics of a light, open texture may be produced in vast variety. Before concluding our studies we shall devote considerable attention to lace-making by itself.

**Velvets.** Velvet is the most beautiful of all the pile fabrics. By a pile fabric we mean one the surface of which is formed by warp or weft raised above the ground of the fabric. As commonly understood the term velvet is only applied to the pile cloth formed by silk warp. We say that velvet is formed by the piling, or looping up, of a silk warp, but the question comes, How is it done? Velvet is composed of two warps, one the pile and the

141. SECTION OF VELVET

other the ground [141]. The loops are formed by passing wires across the web, so that the silk warp must weave them in with itself. Before passing over the wire, the pile warp goes under a weft thread; and, after coming over the wire, is again bound down by a weft pick. But the ground fabric must also be taken into account. One ground warp thread comes up over the weft thread, and accompanies the silk, excepting that it passes under instead of going over the wire. At the second pick, however, this warp thread binds over the weft thread, and passes under the next. Thus the silk is bound closely into the ground fabric and supported by it. The highest class of velvets are cut by hand

with a guide knife, which we shall see when we come to look at the velveteens; but the great mass of the fabric is cut by a small blade at the end of the looping wire. To ornament this precious cloth has always been the ambition of the artist designer. One method much favoured is the alternation, or varied distribution, of cut and uncut pile. Velvet and "Terry," as this combination is called, produces very pretty effects. Another method is the introduction of extra silk or silver or gold threads for figuring. If this be well done, no more magnificent fabrics could be imagined. The last which calls for special mention is the figuring by means of vari-coloured velvets. To do this successfully we must stain every thread in sections so that the point of each cut thread will show exactly the colour needed in the figure.

**Velveteens.** Cotton velvet, or velveteen, is a fabric which has many uses. Instead of the pile being formed by the warp, as in velvet, a floating weft makes the loops which are afterwards cut into pile [142]. While velvet might remain with loops uncut, velveteens must always be cut. An imperative necessity arises in the latter case for the floating threads forming the pile being well bound in the structure of the fabric.

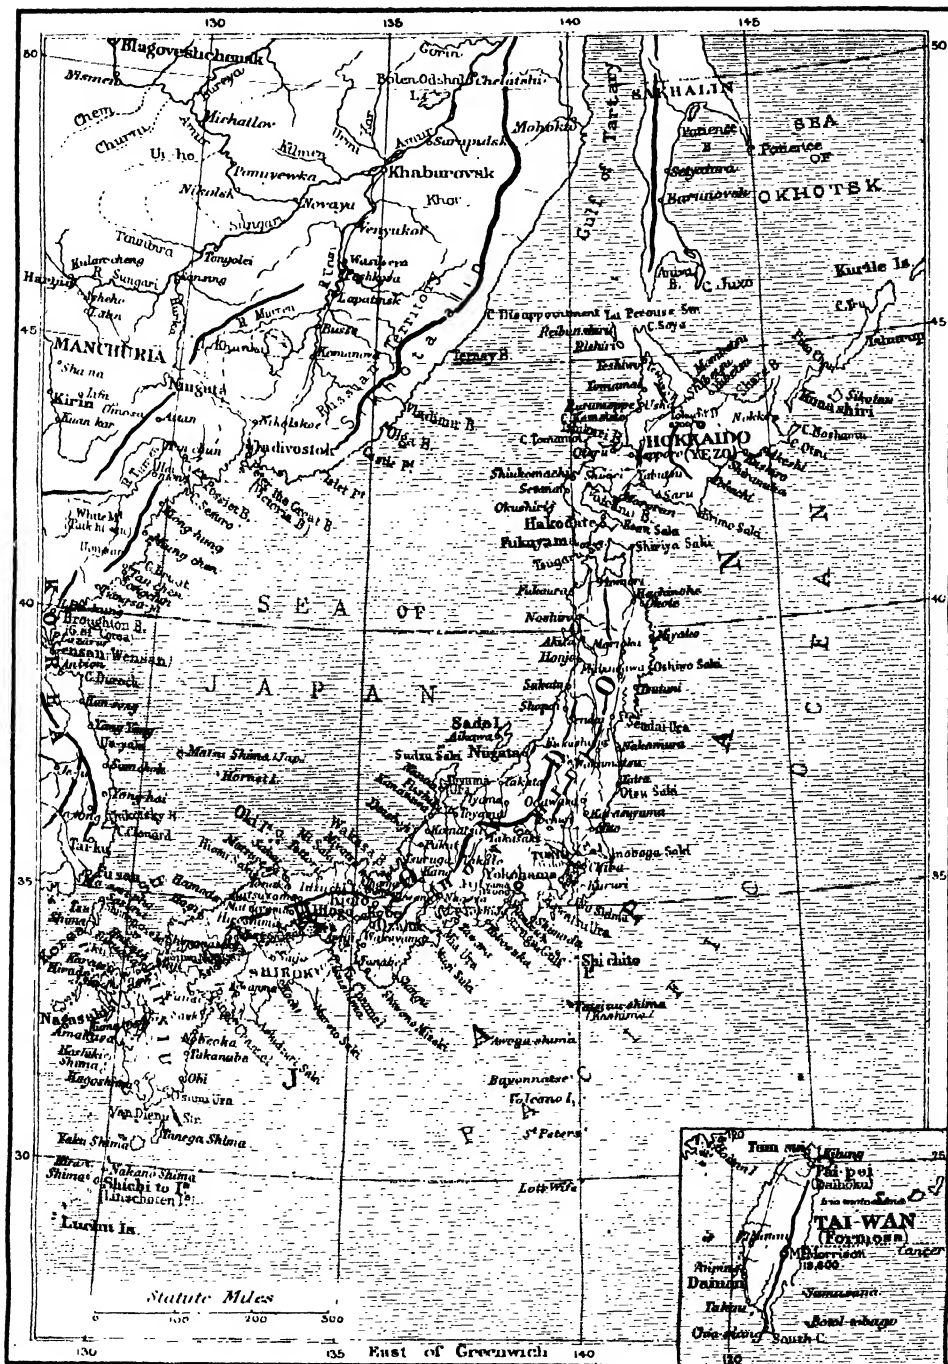

142. SECTION OF VELVETEEN

If not strongly secured the pile will readily come away from the cloth and render all our labour useless. This problem has exercised the minds of many experienced designers. There are many things to be taken into account. For example, the number of floating weft threads we weave together depends wholly upon the quality of cloth we have to make. Similarly, the length of float, whether over five, six, or seven warps, depends on the length of pile desired. These conditions materially determine the pattern to be adopted for binding the floating weft threads. One good rule may be given. The weaving of the ground weft threads should always be contrary in interweaving with the warp at the point where they bind into the warp.

**Chenille.** This is a peculiar kind of plush, or velvet; it can hardly be called a cloth. Chenille is largely used in fringes of various kinds. But it derives an added importance from the fact that it forms the weft of the Patent Axminster carpet. Weft and warp may be of wholly different fibres; in the case mentioned the weft is worsted and the warp is linen or flax. In the best chenilles the warp is set gauze fashion, but in groups of threads separated by exactly double the length of the fringe we propose to make. The weft is woven in the ordinary way, floating between the warp threads, but otherwise interweaving with the warp in common gauze style. When the web is completed, the "cloth," if we may give it the name, is shorn through to the centre of every floating section of weft. The product is firmly bound fringes, which may be twisted for various purposes or kept plain for use in the carpet loom.

Continued from  
page 2577

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

**The Japanese Empire.** The Japanese Empire (161,000 sq. miles) consists of five large and 600 small islands, forming a double festoon from Kamchatka to Southern China. The chief groups and islands are (1) the barren Kurile Islands; (2) Hokkaido or Yezo, the most northerly of the larger islands, separated by a narrow strait from (3) Hon-do or Honshiu, the largest island, off which lie (4) Shikoku and (5) Kinshu; while (6) the long Luchu group connects the islands named, which form Japan proper, with (7) Formosa, taken from China in 1895. The southern half of Sakhalin was added to Japan in 1905.

The Japanese Empire stretches from the latitude of Northern France to south of the Tropic of Cancer, and varies in climate from temperate to tropical, modified somewhat by oceanic conditions. All the larger islands lie in the monsoon area, and have abundant rains.

**Japan.** Japan proper is everywhere mountainous, and large plains are rare. The island lies on one of the great world lines of volcanic activity, and volcanoes, active and extinct, are numerous. Of many extinct cones, the most perfect is Fujiyama, the sacred mountain of Japan (12,000 ft.). Owing to the abundant rainfall, dense forests cover three-fifths of the area. With the world's demand for timber rapidly increasing, as the supply decreases, this is a valuable national asset, and the Japanese wisely pay great attention to scientific forestry. The rivers are numerous, but short. Though too swift for navigation, they serve to float down timber, to irrigate the cultivated lowlands, and to generate power.

Among the forest trees are the sago plant and bamboo, both found as far north as Tokio, the lacquer tree, the camphor laurel, etc. Familiar trees are the pine, elm, chestnut, and beech. A beautiful tree is the cryptomeria, a stately cedar. Flowering shrubs are everywhere, for Japan, even more than China, is a flowery land.

**Fujiyama.** No one can think of Japan without thinking of Fujiyama, or Fujisan, which figures in every Japanese picture. "Living at Tokio," wrote Sir Edwin Arnold, "or Yokohama, or anywhere along the Tokaido, the southern road of Japan, you would soon see how the great volcano dominates the landscape and becomes an indisputable element in the national scenery. Far away at sea, when approaching Japan, long before the faintest blue line of coast is discernible, there is seen hanging in the air a great white symmetrical cone. That is Fuji. After you have landed, you will always be seeing Fuji from some garden, some tea-house gallery, some grove of cryptomeria, or thicket of bamboo. There are loftier peaks, of course,

but there is none which rises so proudly alone from the very brink of the sea.

"It is a circuit of 120 miles to go all round the base. The lower portion is cultivated to a height of 1,500 ft., and it is a whole province which thus climbs round her. From the border of the farms begins a rough and wild but flowery woodland, which stretches to 4,000 ft., where the thick forest belt commences. Above the forest extends a narrow zone of dwarfed larch and juniper, after which comes the bare, burnt, and terribly majestic peak itself." In winter the snows extend half down the mountain's colossal sides, adding the last touch to its beauty.

**Japanese Agriculture.** The lowlands of Japan are only one-fourth of its area, and only one-sixth of the islands is cultivated. Nevertheless, the population is very dense, and agriculture is the chief occupation. Many causes account for its success. The first is the laborious industry of the people, who practise spade cultivation and till their farms with the care of gardeners. Secondly, no fertilising matter is wasted in sewage, so that manure is abundant. The third cause is the prolific nature of the staple crop—rice. All rice lands are densely peopled. The fourth cause is the frugal habits of the people, who can subsist on a scanty diet of rice and fish. These causes have hitherto enabled Japan to support her large population at home; but the pressure is now beginning to be felt, and the Japanese, like the Chinese, seem destined to colonise extensively around the shores of the Pacific. Owing to the value of land for agriculture, livestock has never been important in Japan, though horses are now being bred for military purposes.

**Japanese Crops.** Rice is the staple cereal, with wheat as a winter crop. Barley and beans are largely grown. Most farmers breed silkworms. Mulberries are planted in rows between the crops, to which they give shade. Tea is the second staple. It grows well south of Tokio, and is found wild on the hills of Kinshiu, Shikoku, and Formosa. Native cotton is very short in fibre; American cotton has been introduced, but the demand of the cotton mills is not yet met. Tobacco is a Government monopoly. Fruit is grown for export; the cherry and plum have been planted from time immemorial for the beauty of their blossoms.

**Fisheries.** The seas around Japan swarm with fish, and the shores are everywhere indented with good harbours, while the wooded hills surrounding them provide timber for boat building. Nearly 1,000,000 families are employed in fishing, and fish is a staple of Japanese diet.

**Minerals and Manufactures.** Coal is found chiefly in Hokkaido and Kiushiu. Iron is abundant, but is not found near coal. Petroleum is widely distributed, and Japanese copper is of very fine quality. The arts of Old Japan were no less exquisite than those of India, including wonderful lacquer work, porcelain, cloisonné, and other decorative metal industries, painting and embroidery. Within the last fifty years the industries of the west have developed rapidly. The hideous mill chimney is now a common sight in the exquisite Japanese landscape. With their frugal needs and extraordinary technical skill, the Japanese will soon become powerful rivals in the markets of the world. Osaka, on the Inland Sea, is the Manchester of Japan.

**Japanese Towns.** Hakodate, in Hokkaido, near rich coalfields, is the outlet for the resources of that island. In Honshiu, the

facing China. The Chinese form a large element in the population, cultivating sugar, rice, tea, indigo, fibre plants, etc., in the plains and valleys.

**The Philippine Islands.** This archipelago, including 1,200 islands (115,000 sq. miles), the largest of which is Luzon, belongs to the United States. All are mountainous, volcanic, densely forested, well watered, and extremely fertile. Tobacco and Manila hemp are the most valuable products, but all tropical produce can be grown. Many of the varied tribes are at a low level of civilisation. The capital is Manila, on Luzon.

**The Malay Archipelago.** Of the innumerable islands which form this archipelago (783,000 sq. miles), the largest are Borneo, Sumatra, Java, and Celebes, all Dutch except part of Borneo: all are mountainous and volcanic.

The climate is tropical. The equatorial belt has rain all the year round, but outside this belt the wet and dry seasons are well marked. The

122. FUJIYAMA FROM TOKAIDO

capital is Tokio, with many industries, including shipbuilding and chemical and engineering works. The port is Yokohama, at the entrance to Tokio Bay, with an enormous trade. Further south is Nagoya, the largest town on the Tokaido line, which connects Tokio with Kioto, the ancient capital situated near Lake Biwa, the largest lake in Japan. A few miles distant is Osaka, already mentioned. The chief port of Southern Honshiu is Kobe, on the Inland Sea. In Shikoku, Tokushima is a flourishing town. The commercial centre of Kiushiu is Nagasaki, a fine harbour, near rich coalfields.

**Formosa.** Formosa is mountainous in the east, where the cliffs rise sheer 6,000 ft. from the Pacific. The mountains are densely forested and inhabited by wild head-hunting tribes. Camphor is the chief product of this region. The western half is a lowland with good harbours

forests are of tropical density, and produce rubber and other useful substances, which are collected by native tribes. They are the home of apes, elephants, tigers, and many exquisite birds and insects. Borneo, the largest island, is as yet little developed. British Borneo, in the north, grows tobacco, coffee, and pepper. Dutch Borneo exports tobacco, pepper, sugar, rubber, and other forest produce, edible birds' nests, and strange produce of the sea, including *bêche de mer*, or sea slugs, a Chinese delicacy, and tortoise shell. The best cultivated of the islands is Java, with fertile volcanic soil, producing coffee, sugar, tea, indigo, cacao, tobacco, spices, rice, and sago. The capital is Batavia, the great emporium of trade in the archipelago. The products of Sumatra and Celebes are very similar. The Molucca Islands, between Celebes and New Guinea, produce cloves and other spices.

# CHROME AND OIL TANNING

Chroming Solution. Departments and Method of Chrome Tanning. Fat-liquoring. Sumach Tanning. Tawing. Alum Tannage. Oil Tanning

By W. S. MURPHY

IN their search for new and quicker methods of tanning, leather manufacturers have tried many substances, and one of the most important results of the quest is the process known as *chrome tanning*. Invented as early as 1858, the process can hardly be said to have settled into a uniform routine, many tanners claiming to have devised special processes of their own. Practically, however, this may be regarded as a harmless and not altogether despicable vanity. The workman who refuses to follow others in a blind routine is entitled to lay a flattering unction to his soul, if he can find it.

**Chrome Tanning.** Chrome tanning marks the definite entrance into practical leather manufacture of the chemist and the engineer. It is a chemical process chemically controlled, and operated by machinery. In some tanneries chrome is combined with vegetable tanning, and the old pits are used; but that system is like the attempt once made to combine wood and steel in the armament of battleships, and doomed to similar extinction. The chrome-tanning department of a great belt works presents a fair picture of what the tanneries of the future will be like. The open yard and the tan pits are gone, and instead there are the revolving drums, the whirring machinery, and a laboratory annexed. Cavallin, a Swedish apothecary, invented a process

of chrome tanning; but it was not of much practical value, his use of iron salts making the fibre of the leather tender. Swan, the electrician, patented a process; but he, too, failed to make it practical. Heinzerling, a German chemist, invented the first chrome process to be of any practical use, in 1879. Though not a complete success, Heinzerling's process showed the way to other and successful inventors. The first adaptation of the principle which became really industrial was devised in America by a New York chemist named August Schultz, in 1884. This patent was brought over the Atlantic, and successfully operated. Subsequently, manufacturers of tanning chemicals, British, German, and American, patented chrome mixtures, and sold them to the trade, with directions, thus universalising the process.

Chromium is a metal derived from chrome iron ore, our supplies of which are chiefly found in the Shetland Isles. The metal is grey in colour,

very fusible, and combines readily with many other chemicals [see CHEMISTRY]. Leaving aside those scientific details which must be studied in the laboratory, we come to the actual operations of the working tanner. He gets the mixture all ready, and his business is to work it properly.

## Departments of Chrome Tanning.

Chrome tanning, as generally practised, involves three processes: (1) chroming; (2) neutralising; (3) fat-liquoring. The chief tool of the chrome-leather tanner is the drum [6]. This is a huge barrel-shaped wooden cylinder, 10 ft. in diameter, the inside circumference studded with shelves projecting inward, like the paddles of a water-wheel. On the spindle which drives the drum three spokes are fixed. By means of the spokes and the paddles the hides are tossed to and fro in the liquor. The drum is partially filled with liquor—about 10 lb. chrome alum to 100 lb. of pelt—and the hides plumped in; then the door is closed, and the driving belt put on. For as long as seems necessary the drum keeps revolving night and day, and the skins come out yellow in colour and impregnated with chrome.

## Removing the

**Chrome.** The goods are now tanned, but the acids in the chrome would quickly eat into the fibres if left free to act. Several mixtures are recommended as efficient neutralisers; but our old friend

boric acid, beside being familiar, has the merit of acting quickly and effectively. Having been washed in warm water to take out the intense yellow tint, the hides are placed in the neutralising drum, and it is set going on its round of duty. The composition in the drum varies greatly, but the best authorities advise 1 part of boric acid in 200 parts of water.

**Fat-liquoring.** In ordinary vegetable tanning, the application of fat or grease is considered the business of the currier, or finisher; but fat-liquoring is an integral part of the chrome-tanning process. If allowed to dry after coming out of the neutralising drum the leathers would become hard and stiff. Flexibility in light leathers, and in all classes of belt leathers, is an essential quality. The liquor is an emulsion of soap and oil, in warm water, the proportions varying with the kind and quantity of both ingredients. Castor, cod-liver, and olive oils emulsified with soft soap, curd soap, or wool

6. TUMBLERS FOR TANNING  
(Joseph Hall & Co., Leeds)

grease, give the best results; but if he wants cheaper oils, the tanner may experiment with any mineral oils and alkaline soaps he fancies, and work them in the drum [7]. The mode of operation is simple, the great point being to keep the hides constantly immersed in the emulsion, thus securing thorough permeation. Chrome leather tanning produces a very flexible, tough leather, specially serviceable to the machine-belt maker. Unlike most other mineral tannages, the chrome-tanned leather does not stretch, and this, it is obvious, must be regarded as the highest quality for the purpose named.

**Sumach Tanning.** The aim of sumach tanning is not so much to produce hard-wearing leather as leather that will remain unaffected by atmospheric and noxious gases. Hence most of the leathers which have come down from ancient times have been sumach-tanned. It is a curious fact that this soft leather, almost fragile, remains untouched by sunlight, gas, or change of temperature, while the stolid, strong sole leather crumbles under the rays of the sun. Manufacturers who specialise in bookbinding, upholstery, and ornamental leathers, adopt the sumach process. It is very seldom that this tannage is employed on any but the lighter skins, such as calf, goat, sheep, and seal. As has been already shown, these skins pass through the processes of puering and drenching, coming to the sumach tanner white and soft. The sumach liquor is warm, and either in a drum or a small tank worked with inside paddle [8] the skins are permeated with the sumach. For many generations the tanners of the East have practised a method of sumach tanning which has been adopted to a considerable extent in this country and in America. This is to sew the skin in the form of a bag, flesh side out, to fill the bag with sumach liquor, and to let it float in the drum or tank till the weight of the skin has expelled the liquor from the bag. Sometimes the liquor is expelled by slow pressure. This produces a leather with a soft, velvety feel.

**Tawing.** Kid and glove leathers are chiefly produced by what is called the *alum* or *tawing* process. Lamb, calf, and kid skins are treated

in this way. Young and tender as they are, these skins must be gently treated. Two methods are adopted, with minor variations, the one being more generally employed on calf and kid skins, and the other on lamb skins. At the risk of slight repetition, we will go rapidly through both processes from start to finish.

7. TANNERS' AND CURRIERS' DRUM

**Tawing Lamb Skins.** If the skins have been dried, they must be steeped in cold water for three or four days, and then worked on the beam with a blunt knife to make them pliable and to open out the fibres. When made supple, the skins are stretched on boards, flesh side up, and coated with milk of lime. Laid in piles, the limed surfaces in contact, the skins are left for about ten days, when both the fat glands on the inside and the epidermis on the outside will have been thoroughly loosened. With a blunt knife, on the convex block of wood we term the *beam* [2, page 2854], the skins are divested of hair and washed in weak limewater. Taken out again, the pelts are run over on the beam on the flesh side with a knife, and freed from the flesh and inner cellular tissue. Washed once more, they are puered in a concoction of dog's dung, or erodin, and now become soft, velvety, and flaccid.

Fleshed carefully [9] to remove any excrescences which may have escaped the first fleshing, the skins are rinsed in warm water, beaten, paddled in cold water, and *perched*—that is, worked over the beam with flat plates of vulcanite to remove any fat or lime compounds that may have remained. Now they are washed, and then pass into the drench-tub, where the brew ferment separates finely the fibres for the alum tannage.

**Alum Tannage.** At this point a difference between the practices of Scottish and English tanners must be noted. English tanners make up one tawing liquid, and the Scots make two. The latter process is the slower. A liquor is made up of alum, salt, and water, the strength depending on the thickness of the skins to be tawed, and through it the skins are drummed,

8. TANNING IN PADDLES

These photographs were taken in Elswick Leather Works, Newcastle

## LEATHER

After this, the paste, consisting of flour, wheaten bran, and yolk of eggs, is put into the drum, and the skins worked till they have absorbed nearly the whole of the paste. In English tanneries, the practice is to make a mixture in the following proportions: 5 per cent. flour, 2.5 per cent. alum, 1 per cent. salt, the yolks of 25 eggs, 2 oz. of olive oil, and 1½ gallons of water to every 100 lb. of wet pelts. Then the whole is mixed together, the water being at 100° F., the flour in the form of a smooth paste being added first, and next the oil and the eggs well beaten together, and finally the alum and salt. The pelts are put in this mixture, and the tawing done in single operation. The finishing processes for all tawed leathers is almost the same, and we shall therefore treat them in a final paragraph.

9. FLESHING MACHINE (Joseph Hall & Co. Leeds)

**Tawing Calf Kid.** After being washed and softened, the calf skins are limed in fresh lime in the style of the large hides, unhaired, washed, and worked on the beam. The drenching differs from that applied to lambskin, being done more thoroughly, as a partial substitute for puering. The above mixture is also applied to the calfskin, but the process of tawing is longer, because of the greater thickness of skin. When fully tawed, the skins are allowed to lie a day or two in a tank, to let them take up all the mixture they can hold, and, when partially dry, split on the band knife [10], to be described in a later section.

**Ageing and Finishing of Tawed Goods.** Tawed leathers are dried in a warm atmosphere, though not too quickly. When dried, the leathers are hard and horny, and to soften them a process of *staking* [11] is carried through. Small skins are slightly damped back and worked vigorously, first over a blunt blade fixed in a post, and then under a rounded blade of hard wood called a *moon knife*, because of its shape. Several times the skins are damped back to ease the fibres and allow them to stretch without breaking, and staked over again. Lambskin and calf kid are staked on machines of various shapes, the most common being the

Sloccomb, a two-armed tool, the one hand holding a pair of small rollers and the other a pair of blades, working backwards and forwards, at each turn letting the leather slip a little. When the workman is satisfied that no more staking need be done at this time, the skins are put away to age, or season, for a period of about three months, to fix in the alum of the tawing mixture. In time the skins are brought out again and wetted throughout to take away all the superfluous tawing matter, and to soften for the dyeing. Then the leather—for it is no longer skin—is put into a mordanting bath of soap and ammonia.

**Dyeing.** The common colour is the yellowish flesh tint, and this is made up of two-thirds logwood and one-third fustie, with a small addition of soda. When dyed, the colour is fixed by the application of a wash of iron liquor. When dry, the leather is staked again to take out the stiffness the dye may have imparted; then it is rubbed over the grain or hair side with a mixture of oil and wax, and ironed with a heavy flat iron or passed under a brass roller. To the

ordinary eye the leather seems quite finished, but we know better. The gloss is not permanent, and to make it so we take a mixture of olive oil, tallow, beeswax, resin, and gum arabic, and glose it all over the surface of the leather. This fixed by glassing, we give each skin a rub up with a flannel dusted with French chalk, and our goods are ready for the glover, or whoever will buy.

**Oil Tanning.** Vegetable and mineral tannings produce leathers with a certain quality of firmness, which, though highly

necessary for boots, saddlery, harness, and driving belts, does not suit purposes requiring a material combining softness, mobility, and strength. Tawing produces soft leathers; but that process adds little, if anything, to the strength of the skins, and is hardly applicable to heavy hides. In a word, we want a leather equal in most respects to cloth. George Fox, it is true, made himself a suit out of ordinary leather; but George was a kind of martyr and stoic, and that class of man is never sufficiently numerous to keep an ordinary tannery going. If leather is to be worn by ordinary mortals it must be soft, warm, and comfortable, as well as more durable than woven cloth.

Perhaps the modern leather manufacturer should have left the clothing market to the rivalries of textile workers, though it is risky to venture such an assertion. Modern competition drives industrial enterprise to great lengths; when we see papier mâché offered in lieu of steel for waggon wheels, and spun glass for silk, it is possible to believe that any industry may encroach on the domain of any other.

**Soft Leathers.** The modern leather manufacturer, however, was spared the trouble of initiating the soft leather industry, that which enters into competition with certain cloths. At the time when the textile workers were just

beginning to learn their craft in Europe, the leather men were supplying their fellows with clothes. It was soft leather Achilles wore under the armour he donned to avenge the death of his friend Patrocles in that momentous struggle between the East and the West long ages ago. Nearer to our time, and more certainly, the mail-clad warriors of mediæval Europe shielded their skins from the hard and cold steel clothes so fashionable then with under-clothing of warm chamois leather. The secret, as we have hinted, was discovered long ago; very early in European history men learned that the skin of the little deer living on the higher slopes of the mountains of Greece, the fastnesses of the mountains of Switzerland, the Balkans, and Central Europe, could be made into a soft and durable covering. We live in the days of the far-flying bullet and the street constable, and the soft leather that saved knightly skins from the abrasions of armour-joints now chiefly serves as a kind of superior washing cloth. It is used for purposes more dignified, perhaps, but that need hardly concern us. The important point for the leather manufacturer is that there is a constant and large market for his product, whether it be used for washing windows and cleaning silver or for lining the crowns of seeptried kings.

**Principle of Oil Tanning.** Oil tanning is based on the fact that certain oils combine with the fibrin of skins, and act, not only as preservatives, like other fats, but also as strengtheners of the fibre. Most of our chamois leather is now derived from the split

11. STAKING

skin of the sheep. We have not dealt fully with the splitting of skins hitherto, because splitting is a finishing process in this country for the most part. British tanners prefer to split the hides after they are finished. Suffice it to say, at present, that for the purposes of the glove-leather maker and the manufacturer of parchment sheep skins are split by means of a band knife. The grain side of the skin is taken for these purposes, and the flesh half is given over to the oil tanning department, for the production of what is technically called *washleather*. The splits have already been limed and washed, and the first thing the shamoyer does is to clear away the fatty inner layer with a sharp knife. The operation is not unlike fleshing, but the knife is keener and drawn with sharper force, scraping away all the fatty

layer. Having been thoroughly drenched in the bran ferment, the skins, as they may be called, are drained. If allowed to dry in this state, they would become as stiff as boards.

### The Fulling Stocks.

To make the skins flexible, we put them into the *fulling stocks* [12], those elephantine wooden legs that beat, beat on the sloping trough and drag the skins along bit by bit, pounding them into flexibility. Other models of fulling machines are now used, the favourite form being a pair of wheels that oscillate on each other.

The skins do not go into the fulling machines alone. If they did they would be beaten to fragments. Water as an emollient is out of the question, as we shall presently see, and, instead, a layer of soft

10. BAND KNIFE SPLITTING

## LEATHER

sawdust forms the base on which the strokes of the stocks descend. In addition, however, the British shamoyer adds the cod-liver oil, which is his tanning medium, while the skins are going through the stocks. French and German workers take a different way; but we add slowly the oil to the skins while they are being beaten. Every now and again the skins must be taken out and hung up in a warm room to avoid too great heating through friction. When the skins are out to recover, it is well to coat them all over with the cod-liver oil, and to see that no hard bits are left; otherwise, the leather will be spotty and irregular. The stocking must be continued for many hours, till every fibre of the skins has got as much oil as it can carry. The worker may estimate how the process is proceeding by the gradual disappearance of the limy smell, and the emanation of a pungent mustard-like odour from the skins.

**Heating.** When sure that the skins are thoroughly saturated, the workman stops the stocks, and takes out the skins, examining each one carefully, then laying them in boxes to heat—that is to say, the process of oxidation of the oil sets in. At first great care must be taken lest the heat should gather too quickly and burn the fibres. It is a safe rule to take out the skins after they have lain a short time in the boxes, and lay them out on an open floor to cool. Do this at intervals till the skins cease to give off the pungent odours which bring the water to the eyes. By that sign alone it is evident that oxidation has ceased, and that the skins have been tanned.

**Washing and Bleaching.** Now the skins are ready for washing. First, however, we

should try to recover some of the valuable cod-liver oil which lies unabsorbed by the skins. In the old days, English manufacturers simply washed the skins in strong lye, and recovered the oil by the use of acids; but of late a more economical method has been adopted in many factories. The skins are steeped in hot water, and put under the hydraulic press, recovering a quality of oil which passes into the market as *degras*. Next, the skins are put into a bath of washing soda, and washed thoroughly. While yet damp from the washing, the chamois or wash-leathers are laid out to bleach, watered every now and then with a fat liquor, or an emulsion of

*degras*. The bleaching leaves them of a fair white colour if it be carried out thoroughly, though for the common wash-leather of commerce that is not necessary. It is an important quality of chamois, however, that it bleaches to a pure white if desired.

### Products of Oil Tanning.

Oil tannage is used to produce several forms of leather besides chamois. In fact, the process is so

simple and effective that we are rather disappointed at the slow progress the process has made. Buff leathers for military accoutrements are made from ox hides by this process, the grain side having been scraped off. Curiously enough, the reins and straps used by the Boers of South Africa are prepared by a kind of oil tannage. Cut spirally from the raw hide, and dipped in fat, the thong is wound into a skein and hung from a cross-bar with a heavy weight at the end. Every now and then the fat is applied and the twist of the thong changed, till all the water has been expelled by the pressure, and fat has taken its place. By this means leather straps of great strength and durability are made.

Continued from  
page 2571

By ALGERNON ROSE

TOO much importance can scarcely be attached to the double-bass in an orchestra. It doubles the bass part of the violoncello and is the literal foundation, or "base," upon which rests the entire instrumental superstructure. It is easy to understand, therefore, why the smaller bowed instruments should be named after the great violone.

## Three and Four String Basses.

There are two kinds of double-basses in general use. They are known as the English and the German. The former is provided with three strings, an arched bass-viol bow, and is capable of great power; whereas the latter has four strings, and a straight bow of 'cello pattern is used with it. Modern composers write chiefly for the four-stringed bass, because it can descend a fourth lower in tone than the instrument with three strings. The temptation of getting four additional bass notes, rather than consideration for tone quality, has been the chief cause of the general adoption of the German system of stringing.

**Execution and Tone.** But the fact remains that a good player on the triple-strung English bass can elicit a more telling tone from it with the old-fashioned bow than can the performer on its quadruple-strung Teutonic cousin. Advocates of the four-stringed bass emphasise that certain Italian makers originally planned the biggest pattern of fiddle to carry four strings. They argue that the restoration of the fourth should not lessen the tone of the other three. But they conveniently overlook the fact that the reduction of the six strings to four on the treble viol, during its

evolution into the violin, immensely enriched its tone.

The beginner, whatever he does later on, had better first learn the English double-bass with three strings. An instrument of fair tone is obtainable in Great Britain, nowadays, for about £5. As soon as the student is able to help in an orchestra, he will find that, like the kettledrums, the society generally provides an instrument for the double-bass player. Excepting in large professional orchestras, such basses have three strings. So useful are amateurs who can play this instrument with tolerable reliance, that, in many societies, not only is a bass hired for them, but they pay a smaller annual subscription than the other members.

**Attitude.** On account of the size of the double-bass, the performer stands to play. During lengthy practice a useful support will be afforded by the ledge of a high stool. Grasp the neck of the bass near the head, place the first finger of the left hand on the middle string, put the thumb on the opposite side of the neck immediately underneath, and rest the third and fourth fingers on the third string. Place the left toe under the bottom edge to keep the bass at its proper angle. Suppose the bridge of the instrument represents the centre of a clock-dial and the neck its long minute hand; if the latter points to the hour of one, the angle is correct.

With the right hand take up the bow. Put the thumb on the hair inside, and near the nut. Rest the other fingers above the thumb on the stick. The instrument being

Ex. 1. *Very slowly.*

Ex. 2.

TWO NOTES WITH ONE BOW

at an angle to the player's body, it would be awkward always to bow parallel with the bridge. It is therefore customary for the bow to incline downwards towards the bridge from the third to the first string. The point of the bow, when on the first string, should be just over the top of the left sound-hole.

**Tuning.** Even as the pitch (A) of the first string on a violoncello is an octave below the pitch (A) of the second string of the violin, so the harmonic A of the third string of the English double-bass can be tuned an octave below the A, or first string, of the 'cello. As this A is a very deep note on the bass, it is better to begin with the first string. Tune this in unison with the G, or third, string on the 'cello. If the pitch is taken from a piano, tune to the G, fourth space, bass clef. Instead of scraping forcibly, a less distracting method is to place the tips of the fingers of the left hand lightly on the middle of the string.

**Harmonic Sounds.** This plan, when the note is bowed, will give the harmonic, an octave above the actual open sound. Having raised or lowered the peg of the string first until the harmonic is in unison with the tone of the fourth string of the violin (G, fourth space, bass clef, on the piano) take the hand off and bow the string. Its open sound will then be G, first line, bass clef. This gives what is known as the tone of an 8 ft. organ pipe. Tune the second string to D, in the same way by the harmonic, a fourth below the first. Lastly, tune the third string to the 16 ft. A, a fourth below the D. This is the English method with the three-stringed bass.

Unfortunately, there are other systems. Although violins, violas, and 'cellos are uniformly tuned to the same notes in different countries, the French tune their three-string basses in fifths instead of fourths. This is awkward for the hand. In France, therefore, in place of the first string being G and the third A, the first is A and the third becomes G.

The beginner is warned not to adopt the French method nor to lower the A string to G, as is often done. When the double-bass is tuned, English fashion, in fourths, the scale lies under the hand more conveniently. Moreover, when progress has been made and the student takes up the four-stringed bass, he will find that instrument also is tuned on the first, second, and third strings to D, G, and A in the way he has learnt. The new string will then be E, at a similar interval of a fourth lower down the scale.

**Fingering.** The reason why tuning the bass in fourths instead of in fifths, as obtains on the 'cello, viola, and violin, is more convenient is because of the greater length of the strings. These necessitate longer stretches of the left hand for stopping the ascending or descending notes. Thus, when four fingers are placed close together they represent the natural position, or an interval of a half-tone. If, on the other hand, the fingers are spread out, they occupy the space necessary for stopping the interval of a whole tone. The student who grasps this idea has the fingering of the double-bass in a nut-

shell. When the notes do not occur on an open string, they are usually produced either by the first finger singly, or all four fingers together. In double-bass music, these methods of fingering are indicated by Exs. 1 and 3.

Play the open note of the third string, A. Use the bow from end to end. Count ten slowly. Then place the first finger firmly on the same string; at the same time sound the note B with a full bow. Close the four fingers to get the half-tone above, and with the next bow play C. Without pause, sound the open note of the second string, D. Play the E above with the first finger.

But the pupil will perhaps say that it is the E below. It must be remembered that the expression "up" or "down" the fingerboard of the double-bass refers to the ascent or descent of the tone; it does not relate to the direction in which the scroll of the instrument points. With the four fingers closed to make the semi-tone "above" E, play F. Continue on the first string, sounding the open G. With the first finger get the A above. Separate the four fingers for the whole tone B. The beginner will now have played a full octave and one note. Descend the scale by stopping each interval in the same manner.

By changing the order of these notes, the student can familiarise himself with the different intervals by a variety of exercises. Practise these very slowly at first. Cultivate a good tone rather than a rapid execution, especially in the lower register of the instrument. To play the double-bass well requires muscle. It is excellent for one's health, because it expands the chest, strengthens the arm and wrist - in fact, professional double-bass players are noted for living longer than any other class of musicians.

**Not a Transposing Instrument.** In writing out exercises, the student will note that all sounds for the bass are indicated an octave higher than their real pitch. Not only does this facilitate the reading of double-bass music, but it allows the 'cello and double-bass parts to be indicated by the same notes, those for the former instrument having their tails turned up, and those for the latter their tails turned down. It is incorrect, therefore, to call the double-bass, as some pedagogues are fond of doing, a "transposing" instrument. Unlike the A♯ clarinet, or E♭ trumpet, which transpose their sounds mechanically to other regions of pitch, the double-bass always emits similar sounds to those written. The player, therefore, who is a purist, has only to imagine the words "8ve lower" written over the bass part to satisfy his conscience. If, as sometimes happens, a composer writes below the possible compass of the double-bass, the critic can then mentally obliterate the words referred to. The double-bass will do its best by putting in the notes in unison with the 'cello.

**The Scales.** Now take the scale of G major, with one sharp, F. Begin with the open note on the first string. Spread out the four fingers on the second string to get F♯, instead of closing them, as was done for F♮. With the

first finger, make the next note, E. Then sound the open D. Bow slowly. Count, so as to make each stroke equal. With the four fingers closed on the third string, stop the C. Make the B, half a tone lower, with the first finger, and the A with the open note of the third string. This does not complete the octave, but it accustoms the player to the F $\sharp$  on the second string.

Try the scale of C major. Begin with the four fingers closed on the third string. As before, get the D and E on the second string. For the semitone F above, close the four fingers. As previously, make the G and A on the first string. Separate the fingers to get the B, a whole tone above. To play the C, a semitone beyond the natural position of the hand, shift the latter up the neck (or down, in a gravitational sense) till the four fingers, close together, stop the sound.

**Alternative Fingering.** There are alternative methods of fingering these same notes. The student should familiarise himself with them. We refer to the first string, from G, fourth space, to the C above and back again. First, there is the fingering already indicated. Secondly, play the open string. Then stop A with the first finger. Carry up the same finger to stop B. Next, with all four fingers close together, play the semitone C above. Return in the same way. The usual plan is to play these notes, interchanging the first with the four fingers, by stopping the A with the first finger, the B with the four fingers, the C with the first finger, going back to the four fingers for B and the first finger for A. But this system carries the whole hand higher than necessary up the fingerboard. In double-bass playing, one of the arts is to avoid wasting energy by superfluous shifting of the left hand. Besides being unsightly, it is fatiguing. It makes the performance uneven instead of, as it should be, firm and clear.

**Hand Movements.** Remember, therefore, not to move the whole hand about unprofitably. Practise slowly, and restrain the desire to run before learning to walk. So that the hand may come into its right place without thinking about it, and passages may be fingered readily and correctly, the student must be careful to be right in his first attempts. The road to success is by regular daily practice. A steady quarter of an hour of slow, strong bowing three times a day, with intervals in between, does more good than an hour's unbroken practice, during half of which time the beginner may feel over-tasked by the unaccustomed strain on his muscles.

To continue the double-bass when fatigued

and the hands are aching is unwise. At such a time, stop practising and give the muscles a rest. Then, with recovered strength, try again.

Now try the scale of D major with two sharps, F and C $\sharp$ . Begin on the second string. Bow the open D. With the first finger get E above. Put down the four fingers spread out for the F $\sharp$ . Sound the open G of the first string. Whether the bow makes a downward or sideways movement, take care to keep the right wrist free. Although, later on, the straight bow of 'cello pattern may be used, the student who practises with the arch bow should be able to get a greater amount of force of tone from it and attack the strings better.

**A Lissom Wrist.** But the effect will be spoilt if this is done with a stiff wrist. The wrist action must be unconstrained. Dragonetti considered the arched bow superior to that with the straight stick, and the pupil cannot go far wrong who uses a bow similar to that of the great Venetian double-bass player, who educated himself in the guitar and violin, and was able to

take a place in an orchestra at the age of eleven. From that period he played the double-bass continuously for no fewer than eighty years, never getting tired of it, but always revelling in its beauties.

Having bowed the open G properly, put down the first finger for A, spread out the four fingers for B, stop with the first finger the C $\sharp$ , a whole tone above, and put down the four fingers closed for the semitone D. Descend the scale with the same fingering.

**Intervals.** Proceed now to practise the intervals of thirds, fourths, and fifths. First get

accustomed to these in the key of G. Note down all such exercises on paper, and transpose them into C major and D major. By such means the student will get an insight into the elementary principles of bass playing. We give specimens of exercises that can be easily supplemented. "U" denotes the up-bow, and "D" the down-bow [Ex. 1].

Next, practise the major scales which have up to four flats and five sharps in their signatures [Ex. 3].

To acquire facility in the necessary shifts of the left hand up or down in diatonic passages, persevere day by day with the exercises given in Ex. 2 till they become automatic.

**Bowing.** Now go back to the scales. Play every two notes with one bow, then every three notes with one bow. Making the tone as smooth as possible, try to get every successive four notes with one bow. Play alternately with an up and down stroke. Determine to

### Ex. 3.

### SCALES

## MUSIC

make the voice of the instrument, deep as it is, sing out evenly with a cantabile effect.

**Staccato.** That method of bowing which is the reverse of cantabile is done by separating each note abruptly. It thus appears to be detached, although the bow is not taken off the string. This is called staccato playing.

Practise the scales systematically, repeating each note so as to make two short, abrupt sounds with each bow instead of one long one. Next make three short sounds with each bow. Then alternate the cantabile with the staccato style, by slurring the first pair of four notes with an up-bow, and making the next pair crisply with a down-bow. Write out these exercises on music paper, and go over the same ground day by day.

**Time.** It is necessary for the student, when practising even the simplest studies, to cultivate a sense of time. The double-bass is called the metronome of the orchestra. It is essential, therefore, for the player of this instrument to be a good timist; and to be a good timist he must possess confidence. No double-bass player who distrusts himself can reasonably expect the confidence of others. The glory of the double-bass player is in his strength, and, as hesitation is a sign of weakness, if he hesitates he is lost. If he plays irresolutely, he may upset all the other performers. Cultivation of the time sense gives certainty to the student's playing. It is more important to attack emphatically the first note of a bar than to try to put in all the sounds preceding the conductor's down beat and be half a second late. The violins may flutter about like flags on a mainmast without much damage, but if the great double-bass, representing the keel of the vessel, is uncertain, the result is disaster.

**Rests.** It is a good plan to train oneself with rest studies. Count carefully when practising, not only the notes which have to be played, but the signs which enjoin silence. Rest exercises may be engaged in profitably when the student begins to tire after a spell of vigorous bowing. Take the exercises already made in various keys and substitute for certain of the notes their time equivalents in rests. Thus, if the study is in common time, and each bar contain four crotchets, arrange so as to play the first bar, keep silence during the second, when the rests must be counted carefully; play half the third bar, counting two crotchet rests to

**Higher Positions.** Consideration of the best situation for the left hand leads up to the study of the higher shifts in double-bass playing. These go by semitones, and are reckoned by each successive new position of the first finger. After the first finger has been properly placed, the notes above are stopped consecutively by all four fingers—closed or extended as the interval is a half or whole tone—the next note being pressed by the first finger, and so on. Thus, by gliding the hand backwards and forwards on the three strings, the same sound may be produced in different ways, and changing the strings during one stroke of the bow rendered unnecessary. We give the different fingerings to show the notes that can be stopped by the same digits on the same strings [Ex. 4].

With the above key, the thoughtful student may compile exercises throughout the compass of two octaves, adjusting the fingering to enable him to take up any position instinctively.

**Pizzicato.** A pizzicato effect is obtainable from every variety of instrument furnished with strings, except the pianoforte. On the violin its production is often brilliant in orchestral passages. Owing to the extent of the vibrating surface, the effect of the plucked string, however, is grandest on the double-bass. When such notes occur, they are marked "pizz." To accustom the student to pulling and letting go the strings with the right hand instead of bowing them, and so obtaining the pizzicato sounds, a useful exercise is to practise four bars with the bow, four bars pizzicato, and so on.

**Harmonics.** Of less use to the orchestral double-bass player, save for the purpose of tuning, is the production of harmonics. Yet these are obtainable with greater facility than on instruments with shorter strings. By touching lightly the strings of the double bass at their different acoustical nodes, the series of overtones can be extended in a manner impossible on the violin. For solo playing those sounds are very effective, the so-called flageolet, or harp tones being exceptionally beautiful. Nevertheless, the function of the double-bass in the orchestra is to sustain or mark the pedal or fundamental notes, whilst other instruments supply the overtones to those fundamentals. For that reason, despite the extensive compass of the double-bass, composers do not write for

### Ex. 4.

#### Natural and Sharp Notes

#### Natural and Flat Notes

complete it; omit the first note of the fourth bar, counting a crotchet rest before playing the next three notes, and so on

it above G, an octave over the open note of the first string.

RAILWAYS  
continued from page 2025

By R. W. WESTERN

THE earthworks of a railway usually account for about a fourth or a fifth of the total cost of construction. It is here that the greatest scope is afforded for skilful and experienced management. One who contracts to build a railway will usually be found to succeed or fail according to the ability with which he effects the shifting of the earth.

The actual conditions under which a railway is built are never ideal. However typical the situation may be, untoward circumstances always interfere with whatever arrangements may have been made to build in a preconceived manner that aims at theoretical perfection.

The builder of a railway must, therefore, be resourceful in expedient, and his arrangements must be elastic. Makeshifts are his standby, his main equipment, as a practical man. One who knows only how to proceed by perfectly correct methods is sure to come to grief; and although it is impossible to expound the infinite variety of makeshifts, we shall not follow the usual plan of omitting the description of makeshift devices.

**Strength of Earthworks.** Earth gives way by reason of the particles of which it consists sliding past each other. This is prevented in two ways: first, by any adhesion which may obtain between the particles, and secondly, by friction. It must be remembered in this connection that solid rock, wherever met with, is included in the general meaning of earthwork as well as ordinary clay, marl, loam, and such soil. In the case of solid rock the force of cohesion is, of course, sufficient to preserve the work in almost any form that may be given to it; though it must be noted that rocks have joints and fissures, and that the material may slip where these occur.

With ordinary earth the force of cohesion may also sometimes be considerable; but seldom, if ever, can it be relied upon as a permanent factor in the preservation of the work. It is in all cases greatly diminished by the presence of water, though often assisted by a moderate amount of moisture; and certain clays, though hard and stiff enough when first excavated, become soft and pasty by mere exposure to the atmosphere.

**Natural Slope.** The only force that can be relied upon for the permanent preservation of earthwork is the friction between the particles composing it. This is sufficient to maintain the side of an earthwork at a uniform slope, whose inclination to the horizon is the angle of repose, or angle whose *tangent* is the *coefficient of friction*.

This angle differs, of course, for every kind of earth, and is so variable that tables or information obtained from books should never be trusted to determine the slope at which the side of an earthwork should be made. In every case observation should be taken of existing earthworks constructed of the same material, or, in default of these, the greatest inclination of the natural surface of the soil in the locality may prove an even more satisfactory guide.

For the purpose, however, of obtaining a general idea of the behaviour of materials most commonly found, the following table may be consulted. The first column shows the greatest height in feet at which the material can be expected to stand *temporarily*. The second column shows the greatest angle at which it can be relied upon to remain permanently in repose:

|                                 | I.      | II.      |
|---------------------------------|---------|----------|
|                                 | Feet    | Degrees  |
| Clean dry sand and gravel .. .. | 0       | 36 to 45 |
| Moist sand .. ..                | 3 to 5  | 36 to 45 |
| Ordinary surface soil ..        | 3 to 6  | 25 to 40 |
| Common clay ..                  | 9 to 15 | 30 to 40 |

**Getting.** The word *getting* is commonly used to mean the removal of earth from its natural position, to transport it in the manner and to the place required by the exigencies of railway construction. The mere getting of earth is most economically effected by means of a steam navvy. The steam navvy, however, can be made to work only in an economical and satisfactory manner when it can be used against a sheer face of earth. Hence—as in most cases where a cutting of earth is to be commenced—the earth begins to rise gradually, and in many cases very gradually, the depth of the cut being at the beginning but slight, and a good deal of work has to be done first of all by hand labour.

Whatever recourse may be had to machinery, there is always a great deal of hand labour required in the shifting of earth for railway construction. The cost of this by itself amounts to a considerable sum, the amount of which is entirely determined by the skill with which the work is arranged. The main feature of good management is to insure that all hands are always fully engaged, and that under no circumstances have men to wait while their work is in preparation.

**Implements.** The suitability of the tools for the work is also important. Even the common and well-known pick, unless it be adapted to the work in hand, will involve an

unnecessary expenditure on labour. There are three kinds of pick in common use; those most favoured are A and C in 1. In getting stiff earth the pick is used a great deal as a lever and is very liable to break at the junction of the handle with the steel. For this reason the pick A is most suitable under these conditions; but that indicated by C is more suitable for all-round general work, and is most favoured by workmen. The pick B is most convenient for work that is level under foot. It will be recognised as that most frequently seen in the hands of workmen mending macadamised roads. It is a common plan in America to plough the land before putting the men on; the object of this is to loosen the surface soil, thus avoiding the use of the pickaxe at all. Such a method is, of course, only applicable where the depth to be obtained is very slight, as, for example, occurs in cases where it is considered desirable that the surface soil should be removed before commencing an earthwork.

**Shovels and Spades.** Two kinds of shovel are required, and they are illustrated in 2. They are not of uniform size, the dimensions varying from 12 in. by 10½ in. to 14 in. by 13 in. The main difference between them is that B is provided with treads—that is to say, an extra piece of metal is placed on the top of the blade where the navvy places his foot to drive the shovel into the earth. These trends lengthen the life of the shovel, especially when used for digging in hard soil; but for shovelling earth into barrows or carts, the treads are superfluous and, by adding to the weight of the implement, cause an appreciable increase in the labour of using it.

A spade, including the handle, should not weigh more than about 6 lb. The earth, after being detached in manageable fragments by the

is adopted directly the *gullet*—as the advancing cut into the hill is called—is 4 ft. or 5 ft. deep, provided a proper *tip-head* is prepared. The use of this latter term will be fully explained when we deal with the subject of tipping.

1. PICKS USED FOR RAILWAY WORK

contact of the wheel and the ground to the handles. If this be too great, the workman will find a difficulty in balancing it, and the effort to keep it steady will diminish his daily output of work. The distance in question should certainly not exceed 12 in.

2. RAILWAY SHOVELS

**Hand Labour.** A wheelbarrow of serviceable size is shown in 3. The men who use picks are called *pick-men* or *getters*; those who use a shovel are called *fillers*; and when wheelbarrows are used the men wheeling them are called *wheelers*. The number of getters must be carefully proportioned to the number of fillers, and the number of these to the number of wheelers, so that the different groups may not have to wait for each other. The proportion of getters to fillers depends upon the nature of the soil. In comparatively new earth an equal number of each will generally keep everyone employed. In a stiff clay, however, one filler will clear away the getting of two pick-men.

Only by experience can a suitable relation be obtained. The proportion of the number of wheelers to the number of fillers depends upon the *lead*—that is to say, upon the distance over which the earth has to be wheeled. As a general rule, it takes as long to fill an ordinary barrow as to wheel it along a plank for 100 feet. This, however, only holds good if the plank be level. If the earth must be wheeled up an incline, every foot of increase in the level must be reckoned equivalent to 6 ft. on the level plank. The lead should be so arranged that under no circumstances have loaded barrows to be wheeled up an incline greater than 1 in 12, otherwise the workmen will not be expending their strength in an economical manner.

**Barrow Work.** When earth has to be transported in barrows a greater distance than one wheeler can go while a filler is filling the barrow, the lead is divided into two, or a greater number of parts, as the case may require. These parts are commonly referred to

### Wheelbarrows.

The great point in the design of a wheelbarrow is the distance of its centre of gravity when loaded from the line joining the point of

3. WHEELBARROW FOR RAILWAY WORK

pick is placed by means of shovels into either wheelbarrows or small carts, except where the cutting is sufficiently advanced for men to be able to throw the earth immediately into waggons running upon the rail. The latter plan

as runs. Where the runs meet, the planks are laid double for a short distance. Thus, in 4 the barrow A is being filled, while the barrow B is being wheeled away full. When the barrow B has reached the position B<sup>1</sup>, it will be left there, and C, the empty barrow left by

4. TRANSPORTING EARTH IN WHEELBARROWS

the second wheeler, will be taken back to be refilled by the first. The second wheeler, meanwhile, having placed the empty barrow D he is now taking back in the old position C, will take on the barrow B from its position at B<sup>1</sup>. In the figure the barrows are shown turned in the direction of movement; but the English labourer does not so turn his barrow, but trundles it behind him when returning with it empty.

**The Steam Navy.** As soon as a cutting has been pushed forward by hand labour sufficiently far into the hill to give an approximately vertical face about 12 ft. high, a steam navy [see page 1822] may usually be introduced with economy, and all further getting, filling, and barrow work, except that required for *trimming* the slopes—that is to say, bringing them to their ultimate profile—is done by its means.

The steam navy enables quicker progress to be made than is possible by hand labour, however great a number of men may be available for the work, since it is impossible to get more than a certain number of men at work upon a face of earth at the head of a cutting; and by means of the steam navy the earth is excavated very much more quickly than it could be by this maximum of men. Its use relieves the contractor of the necessity of getting together so large a number of men, and of housing or otherwise providing for them in out-of-the-way districts. It further renders the contractor or constructor of the railway in a great measure independent of strikes in this department of his business, so that less time is lost in disputes about wages. Thus, when a steam navy has once been got fairly to work in excavating a railway cutting, it may generally be relied on to continue at a uniform rate of progress until the excavation of that cutting is complete.

**Output of the Steam Navy.** The output is, of course, greatly dependent upon the nature of the earth. For hard stuff a small bucket must be used. But in most cases the bucket attached to the steam navy may be of 1½ cub. yd. capacity, and in loose earth or sand a bucket of 1½ or even 1½ cub. yd. may be used with advantage. The most disadvantageous material to work is stiff clay containing large stones and occasional boulders. In such cases

the capacity of the bucket should not exceed 1 cub. yd., and may have to be even less in order to reduce the liability to accidents. The number of strokes or digs that can be effected in an hour is between 50 and 70, and the average is about one a minute, allowing for all the delays involved in moving forward the machine and in laying fresh rails, etc. This gives approximately 600 bucket-loads per day of 10 hours.

Under fairly favourable conditions a steam navy will excavate a cutting 20 ft. deep, 50 ft. wide at the top and 40 ft. wide at the bottom at an average rate of 8 lineal yd. per day. As to the cost, it is to a great extent a matter of wages. The machine requires a wheelman, a fireman, a man at the top, a ganger, an engine-driver, and eight other men to allow for handling the waggons and for shifts, so that altogether the cost of getting and clearing away the earth with the help of the steam navy is about £5 a day in England.

**Manner of Working.** To ensure that the machine shall be kept working at a maximum output, careful attention must be given to the

5. RAILWAY CUTTING WITH A STEAM NAVY

provision for getting rid of the excavated earth. The most effective way is to provide double roads, one on each side of the machine, and branching out from a central road. Immediately behind the machine these roads should be connected by two short crossover lines [5].

A line of empty waggons is kept on the central road between the two side lines, and on each side of the line of waggons is a man tending a horse, by the help of which an empty wagon is

6. ARRANGEMENT FOR STEAM NAVY WORK

brought forward from the line on the central track over the short crossover line and alongside the machine. As soon as a wagon is filled, it is run back along the branch, another empty wagon meanwhile having been brought up alongside the other side of the machine from the central track. Thus the empty waggons are

continually being removed from the central track and passed (filled) into the branch line. Each engine bringing a train of empty waggons pushes them up the central track and leaves them there; it then goes back and passes on to the branch line to take a load of full waggons out of it.

The short crossover lines immediately behind the steam navy have to be continually moved forward as the steam navy works its way through the cutting. It will have been noticed that only empty waggons are passed over them, and under these circumstances it is not surprising that the roughest makeshifts are found to be economical.

#### Waggon Provision for the Navy.

A common arrangement is shown in 6, the details of which are taken from actual practice. The waggon is supposed to be going in the direction indicated by the arrows. The front right wheel comes first into contact with the block of wood 1 at A in the drawing. This block is shaped like a wedge. The flange of the wheel of the waggon rolls up this wedge until the bottom of the flange is on a level with the top of the rail.

Further progress at A is then checked, while the left wheel rolls round B, coming up a similar inclined plane to that already described at A, because the rail it has to mount is at a higher level than that it must leave. To prevent the wheels making off bodily to the right and leaving the line, block 2 is placed at B to keep the flange in position. Both the blocks 2, 2, at A and B now help to divert the wheels so that they drop down upon a crossover line with a jolt. It will be seen from 5 that according to this arrangement the jib of the steam navy has to be swung round a minimum distance at each stroke, the earth obtained by each sweep being delivered on its own side. The gullet thus made may be run to a depth of as much as 30 ft. in loose ground, but the most economical depth is 25 ft., because at this depth the machine has just reach enough to make the cutting of standard size for an ordinary two-line railroad of the usual gauge. It is in making the cutting very much narrower or very much broader than this that extra trouble is involved. When the cutting is narrower there is not room for a line of

waggons on each side; and when it is broader, the navy is unable to reach both sides at the same time, and, consequently, after being run forward as far as the circumstances allow, it must be brought back again and set to widening the cut by excavating on one side of it alone. While so working only one waggon at a time can be placed in position for loading, and the consequence of this is that there is loss of time in cranking the waggon, since it requires less time for the navy to fill its bucket than for the filled waggon to be moved and an empty one put in its place.

#### Getting the Waggons into Position.

In working along a side face, as in the case just described, there are two ways of getting empty waggons into position. First, a train can be drawn up alongside the navy, and each truck as it is filled can be pulled backwards by the locomotive, so as to bring the next one to the right position for receiving the contents of the bucket. This method has the advantage of quickness, and eliminates the loss of time alluded to. In practice, however, it is not found satisfactory, except in the hands of a very skilful engine driver, and with a better track than is commonly laid for the waggons.

7. RAILWAY CUTTING AS LEFT BY STEAM NAVVY

Under ordinary circumstances, the engine-driver will fail to move the train just the requisite distance for bringing the succeeding truck into the right position to be filled. The steam navy will then possibly miss a truck, the movement having been too great, or a great deal of earth may be spilt upon the track because the bucket cannot be brought properly over the misplaced waggon.

The second method is to store the empty waggons behind the navy, very much in the same way as was described in 5, though there can be only one branch line. Of course it is not so convenient, but on the whole this method is more often used than the former.

#### Cutting in

Clay. In cutting a very hard and tenacious clay it is

unsafe to make the cutting deeper than 30 ft., although with loose earth 30 ft. is not very deep. The reason of this is that in digging loose earth, although the bucket may not be able to get near the top of the cutting, yet, while digging underneath, the upper part falls down; whereas in a hard clay, the digging underneath might proceed for 5 ft. or 6 ft. into the

before the earth at the top gave way, when it would be likely to fall in a mass and injure something in falling. Where the cutting is of excessive height for only a short distance, it is expedient to loosen the earth at the top by means of wedges over this distance, so that only small quantities shall fall at a time. The work will involve the employment of several men, and is very liable to lead to accidents. It is only when the distance in question is too short to make any alteration in the scheme for excavation expedient that it should be resorted to. The alternative is to take out the earth in two layers.

8. RAILWAY CUTTING. GALLERIES

**The Steam Navy's Work.** The steam navy leaves the side slopes nearly perpendicular towards the top, especially when the cutting is deep, and these have afterwards to be trimmed to the proper profile as required for the railway. The most economical method of trimming is put into practice immediately after the navy has moved on, or at least before the earth has slipped down. Fig. 7 shows the form in which the side of the cutting is left by the navy. It will be seen that the earth is in an unstable condition, and that its fall is only a

9. ARRANGEMENT OF LINES FOR SINGLE TIP-HEAD

question of time. Hence, if the slopes are trimmed immediately after the navy has left them—that is to say, before the earth has fallen—much labour will be saved, since the workmen have the force of gravity in their favour; whereas, after it has slipped down, they must throw it up again, and usually into railway waggon, which is a high throw.

As shown in 8, galleries should be made along the side of the cut, so that the earth is always thrown downwards, and wheeled along planks as shown, and emptied into waggon alongside.

#### Obstacles to Steam Navy Work.

One of the chief obstacles to the use of a steam navy in settled countries like our own arises from the number of bridges which have to be constructed over the line. These may amount to five, or even ten per mile, and frequently have to be built in trenches before the cutting is made. The steam navy, in such circumstances, cannot be passed beneath it without being taken to pieces, involving great labour and loss of time. In excavating a stiff clay a further objection is found in the condition of the excavated earth. This will consist chiefly of large lumps, 8 cub. ft. in size, and fragments thereof. When the earth is tipped to form an embankment, the large lumps all roll down to the bottom and form the base of the bank, the effect of which is to cause an undue amount of subsequent contraction. This difficulty is discussed more fully under the head of *tipping*.

**Blasting.** When the earth to be excavated is too hard to yield to the pick, the assistance of explosives must be obtained. Slow-burning explosives, of which gunpowder is the type, are most suitable and economical for soft, tough rock, such as are composed of indurated clays; while detonating explosives of the dynamite order are best suited to hard, brittle rocks, like trachyte. Patent explosives consisting of mixtures of these two explosives are often more powerful than either. An account of the use must be sought for under the head of Explosives. The ordinary methods of blasting are explained under Mining, and the

blasting required for railway work does not appreciably differ.

**Tipping.** Earth is either tipped or filled in order to be got rid of or for some ulterior useful purpose, of which the formation of an embankment is the principal. In cases where such an embankment is too far removed from the site of the excavation, or where, for any other reason, it is inconvenient to use the excavated earth for the purpose of forming an embankment or any other railway work, the earth must be tipped upon waste land purchased for the purpose, producing what is known as a *spoil-bank*.

There are two methods by which an embankment may be filled in the construction of a railway. The first is by depositing the earth in layers about 1 ft. thick, and *punning*, or *ramming*, it thoroughly after each layer is deposited. Punning, or ramming, consists of allowing a heavy weight to fall upon the earth from the height of about 1 ft., to which height it is raised by hand, the man using a staff attached to the weight for that purpose. The process is expensive, the cost being approximately equivalent to 1½th as much as that involved in loading the earth into barrows. This method is, nevertheless, used in depositing the earth over culverts and in the proximity of bridges and similar openings.

The other method of tipping the earth is to allow it to fall from the waggon or the vehicle in which it is conveyed from the full height of the embankment which is being formed. This is a much easier, more convenient, and a less expensive method of working. It has the advantage also of being very much more expeditious.

An embankment constructed in this manner may be either tipped to its full width at once by using two lines of way, or, when the work is required to be pushed quickly ahead, a single line may be used for a short distance; but it will be seen from the following description that the single line cannot be made to go very far ahead.

**Single Tip-head.** The arrangement of lines for a single tip-head, as it is called, is as

10. ARRANGEMENT OF LINES FOR DOUBLE TIP-HEAD

follows [9]: The engine first of all drags its train of loaded waggon, which it leaves at A in the figure, the line being here doubled to allow a space in which they may stand. All the waggon are then detached from one another and from the engine. The truck nearest the engine is then reattached to it, not by means of the ordinary coupling, but by means of a hook which can be detached by the engine-driver or stoker on pulling a string. The engine now proceeds with this full truck behind it,

and moves towards the tip by way of the lines marked B. But before it reaches B the waggon is detached, and the speed is regulated so that the waggon following the engine, in virtue of the velocity already obtained, comes to a stop of itself, and is left at B. The engine, which has been proceeding towards the tip, now reverses, and returns to A by passing along the lines marked C. At A it picks up another full waggon, and this it proceeds to leave at B by the same method as before; but on this occasion, in passing towards the tip along the lines marked B, it comes in contact with the former waggon which had been left at this spot. This it now pushes towards the tip-head. It is not attached to the waggon in any way, it simply pushes it forward. This is done with a sufficient velocity to cause the waggon to reach the extremity of the tip at a speed of from four to six miles an hour.

The engine is stopped by putting on the brakes shortly before the waggon reaches the tip-head, as the extremity of the tip is called. The contents of the waggon having been emptied at the tip-head, the engine again comes forward, the emptied waggon is attached to it, and the engine proceeds with it at a moderate speed along the lines marked C. Here it again detaches itself and increases its velocity, so that it gets ahead of the waggon and passes along the lines marked A, there to pick up another full waggon. In the interval the points at X have been altered so that the empty waggon following the engine is directed on to the line marked D, where all the waggons, after being emptied, are ultimately stored, by continuing the cycle of operations already described. The engine then passes along the lines marked A, enters the line marked D at the other end, and the train of empty waggons can be made up, to be carried back to the site at which excavation is proceeding in order to be refilled.

It will be seen from the figure that three points are required, at X and Y and Z; but the points at X are the only points that require the attendance of a man, or rather a boy, to operate them. Those at Z may be operated by a weight in such a way that wheels passing from right to left are always directed along the lines marked C, while those moving in the opposite direction open the points for themselves, the pressure of the flange being sufficient to raise the weight. The points at Y can be managed in the same manner, the weight being arranged so as to direct all wheels moving from left to right along the lines marked B.

**Double Tip-head.** The arrangements for a double tip-head, as a tip-head with two lines of way is usually called, are simpler [10]. The waggons arrive at A, and are left there as before, being detached from each other as

already described. The engine, then picking up the truck first to hand, gets up sufficient speed to enable the waggon to reach the tip-head by its own velocity. This must, of course, be done quickly, for the engine must detach itself and, proceeding at a greater speed, pass on to the lines marked B, leaving time enough for the points to be altered before they are reached by the waggon following it, so that the waggon shall pass on to the line marked C with sufficient speed to reach the tip-head and be tipped.

The engine then returns, and, picking up another waggon, sends it to be tipped along the lines marked B in an exactly similar manner, while the engine itself, proceeding along the line marked C, there picks up the waggon previously tipped, and, quickly getting up a velocity on its way back, detaches itself from the waggon and moves on to the line marked A, leaving the empty waggon behind it to follow at a sufficient distance to allow the points to be altered

so as to direct it on to the lines marked D, and with sufficient velocity to carry it up to the line of empty waggons standing there. In this arrangement it will be seen from the figure that only two sets of points are required, both of which, however, require manual operation.

**Side Tipping.** By means of a double tip-head an embankment may be tipped at once to its full width—that is to say, the necessity for tipping over the side of the embankment may be avoided. This method of tipping earth is very simple, though special waggons are required. These waggons are called side-tip waggons, and where it is desired merely to widen an embankment it is necessary only to bring a train of them on to the embankment, when they are all caused to tip their contents out sideways.

This means, however, is not so satisfactory, in spite of its simplicity and economy. The objection consists in the fact that earth has always a tendency to slip in the same direction in which it falls from the waggon, and if, for any reason, the widening of an embankment by side tipping is not completed until some time after the first work has been made, it is possible that the earth subsequently deposited may never become securely united to the previously tipped earth. The effect of heavy rainfall under these circumstances may be to cause a very serious slide in the earth of the embankment, and perhaps a grave accident.

**Tipping Embankments of Various Widths.** In tipping an embankment for a single line of way the width at the top is generally much narrower than is necessary for the support of the permanent way to be subsequently built; on the other hand, the earth falls down from the waggons from which it is tipped at an angle very much steeper than will provide for the

11. RAILWAY EMBANKMENT FOR SINGLE TRACK  
Showing provisional and ultimate position of earth

12. RAILWAY EMBANKMENT FOR DOUBLE TRACK  
Showing provisional and ultimate position of earth

necessary stability of the permanent earthwork. Under these circumstances it is usual to tip an embankment which is formed under these conditions considerably higher than it is intended ultimately to be. The surplus earth at the top will then be available for easing the slope at the side, as shown in 11, in which the full lines show the profile of the embankment as at first formed, and the dotted lines as subsequently shaped.

In tipping a bank for two lines of way, it is best to keep the two tip-heads at a good distance apart, as shown in 12, so that at the top the bank is at first much broader than is required. The full line in the figure shows the profile of the embankment as at first formed, and the dotted lines show the profile as finally shaped. The triangle between the two heads is best filled by running a single tip-head in a line between the two former tip-heads.

#### Embankments on Sidelong Ground.

In 11 and 12 the level of the earth upon which the embankment is tipped has been shown level. This, of course, is seldom the case, and if the slope of the ground in the sidelong direction is considerable it will be necessary to bench it, or cut it into steps [13], which should be sloped longitudinally for drainage, in order that the earth tipped upon it may get a firm hold upon the ground. Sometimes, especially in America, a better union between the earth and the ground is sought by ploughing the latter before commencing the embankment.

Fig. 14 shows a common way of forming an embankment on sidelong ground. The full lines show the form in which the earth was first tipped, and the dotted lines its ultimate shape. That part of the section numbered 1 was tipped first by means of a single tip-head, and this formed a toe to the main part of the embankment numbered 2, which was subsequently deposited by

14. COMMON METHOD OF MAKING EMBANKMENT FOR SIDELONG GROUND

means of a double tip-head. The bank is subsequently widened if necessary by side tipping, forming that part of the embankment numbered 3.

**High Embankments.** When the embankment to be formed is very high, say 30 or 40 ft., it is usual to tip it in two loads: this is of special importance when the excavation is effected by the help of a steam navvy. This machine, when working in stiff ground, brings out the earth in very large lumps, and when the waggons are emptied at the tip-head the largest lumps are those which roll down to the bottom of the slope. The embankment therefore advances upon a layer of very large lumps of soil, having a bulk of perhaps as much as 20 cub. ft. The higher

the bank the thicker will be this layer of large lumps, and unless they are broken up by hand as the embankment is made, the interstices left between them will be of considerable amount, and will cause the bank to contract and settle down for a long time after it is completed.

By tipping the embankment at two different levels this disadvantage is very considerably diminished.

13. STEPS FOR EMBANKMENT

**The Act of Tipping.** The act of tipping or emptying the contents of the waggon over the tip-head requires some description. The waggon, as has been described, comes forward towards the tip-head with the velocity it has acquired from the engine before the latter has been detached. As it comes forward, a loop of chain is allowed to trail behind it, and immediately before the waggon reaches the tip this chain is caught by a large hook placed between the rails for that purpose. The hook is attached to a hawser, the other end of which is anchored into the bank some way behind the tip. The object of this is to prevent the waggon from falling over the slope of the tip, as it would be liable to do if it reached it with an excess of velocity. The waggon is ordinarily checked by a number of sleepers piled up at the very extremity of the railway. On coming against these, the catches which fasten the body of the waggon to the frame are knocked up by the men at the tip-head, and then the forward velocity of the waggon is sufficient to cause the body to fall over and empty its contents down the slope. The men then pull the body back to its former position and refasten the catches.

**Returning the Waggon.** Sometimes the waggons are designed so that the body falls back of itself to its old position after its contents have been tipped out. The men must detach the hook from the trailing chain, and connect the waggon with the engine, which then comes forward to draw it away. The sleepers piled up at the tip-head to check the waggon have wrought-iron handles at each end to enable the men to move them about easily. They have to be constantly moved as the work of the embankment advances, and are placed contiguously on the earth where the rails end, so that the waggon runs upon them as it leaves the rails. The waggon, of course, is not allowed to leave the rail unless it can be helped; but the embankment, it must be remembered, is constantly advancing, and the rails cannot be advanced in very short lengths. The sleepers are therefore laid in an upward curve, where the rails end, bringing the waggon to a stop, and causing it to run back again upon the rails. The sleepers are cut up very rapidly and destroyed by the flanges of the wheels, but they may be protected by iron.

# OUR WONDERFUL EYES

The Business of the Eye. Its Parts and Functions. Long and Short Sight. Faults of Vision. Imagination and Deception of the Eye

By Dr. C. W. SALEEBY

THE business of the eye is to appreciate light. It is necessary to remember, however, that various other kinds of stimulus may cause sensations of vision, as is indicated, for instance, in the phrase, "I will make you see stars." The technical name for normal vision is *emmetropia*. This word has a puzzling appearance, but the first two letters are really a modified form of the Greek *eu* which means "well." Emmetropia is defined as that state of the eye in which rays from a distant object are focussed upon the retina without any muscular effort within the eyeball, while the near point, so-called, which may be roughly defined as the point at which ordinary type may be comfortably read, is from 5 to 10 in. The child, as we have seen, has a more spherical lens than the adult, and its near point is at about 3 in.

**How Light Strikes the Eye.** In order, then, that these conditions may be observed, what must happen to the light as it passes through the eyeball? The rays of light from a distant object, such as a star (which, as usual, we assume to be parallel), are made to converge on passing through the cornea, which is obviously a convex lens. They converge still further on passing through the crystalline lens, and are brought to a focus upon the retina. The normal eye is such that the retina is approximately in the principal focus of the lens, or, at any rate, in the principal focus of the crystalline lens plus the cornea. Hence it is that all parallel rays (by which term, for practical purposes, we may include all rays from objects 20 yards or more away) are focussed upon the retina automatically or mechanically without muscular effort. The image, as we have elsewhere seen, is, of course, inverted. Now what happens when we look at an object which is relatively near and the rays from which are divergent? Obviously, the optical apparatus which was able to effect accurate focussing in the former case will not be of avail in this.

**Accommodating the Eye to Circumstances.** The mechanism by which the eye modifies itself is known as *accommodation*. Shut one eye and hold a pencil up in front of the other; then, instead of fixing the attention upon the pencil, turn the attention to the window that may be beyond the pencil, so as to observe, as distinctly as possible, whatever may be outside; the immediate consequence will be that the image of the pencil becomes blurred—an experimental proof of the fact which might have been arrived at deductively, that the eye cannot simultaneously focus parallel and divergent rays. In some fishes the mechanism of accommodation corresponds exactly to that

which is employed in various familiar optical instruments—the distance between the lens and the retina is modified according to need. The other possible method (which is not open to, let us say, the photographer, whose lenses are made of glass) is to vary the convexity of the lens, and to do so in proportion to the need. This is what occurs in man. When we fix our attention upon a near object, we deliberately make the lens more convex or stronger, so that the rays, though divergent, are, so to speak, brought to a focus in time. If we did not so accommodate, they would be brought to a focus too late—that is to say, after reaching the retina. By various means of proof, which we need not here consider, it has been shown that what happens when we accommodate is a bulging forwards of the anterior surface of the lens, which, as we have seen, is less convex than the posterior surface when accommodation is not taking place.

**The Ciliary Muscle.** When the eye is at rest, accommodated for vision of distant objects, or *negatively accommodated*, as the phrase is, the ciliary muscle is not in action. *Positive accommodation* is the name applied to alteration in the shape of the lens when the ciliary muscle is thrown into action. It contracts in such a way as to allow the lens to bulge forwards. That is so because when the ciliary muscle is not in action the suspensory ligament of the lens is stretched and flattens the lens; but when the muscle acts it relaxes the suspensory ligament, and allows the elasticity of the lens to assert itself. Helmholtz and many other physicists have studied the mechanism of accommodation, and there has been a good deal of controversy about it, but the description we have given, following Helmholtz, is that generally accepted. If the ciliary muscle be very forcibly contracted, the suspensory ligament is so much relaxed that the lens actually falls a little. This may be shown by a simple experiment—placing two needles horizontally, one 10 in. and the other 40 in. from the eye, but both at the same level. If, now, one looks from the far needle to the near one, it seems to rise a little, the lens having fallen.

**The Resting Eye.** Since positive accommodation is a muscular act, it is fatiguing, whereas negative accommodation is restful. It is for this reason that it is good to have pictures of landscapes in a room, since, when one looks at them, the ciliary muscle is relaxed. The smallest physiological knowledge of what is implied in the contraction of a muscle will also teach that positive accommodation should not be made too continuous. It is a wise habit to close the eyes occasionally when reading or writing, not

merely because this affords an opportunity for thought, but also because it gives the ciliary muscle a little rest. We proceed immediately to discuss short-sightedness, but at this point we may note that the persistent use of the eye at near distances has a definite effect upon it. The structure of the eye tells us that the main use for which it is, so to speak, *intended*, is not the vision of near objects. Indeed, the finely symbolic truth has been recognised that the human eye is naturally focussed upon infinity—not upon the near and petty. Thus, while the eye contains within itself arrangements for the accurate vision of near objects for comparatively short spaces of time, it is bound to suffer if these arrangements are unduly exploited.

**Civilisation and Sight.** A measure of civilisation might almost be found in the degree in which it involves the use of the eye at short distances. The savage earns his meal by seeing the deer on the horizon and sending an arrow through it from afar. The citizen earns his at a desk. Thus the amount of positive accommodation is proportional to civilisation. Now, it is notorious that very many of us are nowadays short-sighted, and the Germans, the most studious people on earth, are the most short-sighted. This fact is not to be explained by the biological doctrine that the eyes of civilised man are becoming weak from overuse and that the weakness is transmitted. Such a doctrine contains at least two errors. The first is that acquired weakness of the eyes can be transmitted at all, and the second that the short-sighted eye is a weak eye. Set the savage to work all day beside a civilised man at something requiring positive accommodation, and one would soon learn which had the weaker eyes. The fact merely seems to be that the persistent contraction of the ciliary muscle actually alters the shape of the eye—as might quite well be expected. The eyeball, as a whole, probably has its shape altered, being made longer from back to front. It is such an eye that we usually call short-sighted. It follows that the short sight of the student is, after all, the result of an adaptation to the kind of work which he makes his eyes do. The more short-sighted his eye the less does he need to accommodate. Of this we shall see a further illustration when we come to consider long sight.

**Short-sightedness.** The technical name for short-sightedness is *myopia*, as distinguished from normal sightedness, or *emmetropia*. Since we have these two terms here, we may contrast with them the other two that resemble them—*hypermetropia* or long-sightedness and *presbyopia*, the particular form of long-sightedness due to the ageing of the eye. The defect of the short-sighted eye is that it is too long from front to back. The consequence is that parallel rays are brought to a focus too soon—at a point in front of the retina. Such an eye is said to be short-sighted because, in order to effect clear vision, an object must be brought near the eye. When this is done, the divergent rays from it are not brought to a focus too

soon. This is why the short-sighted person holds a book near his eyes—in order to make the rays even more divergent than they are in any case. Sometimes the actual defect in the eye seems to be less an undue elongation from front to back than an increase in the curvature of the cornea.

The remedy for myopia is very simple. Lenses must be placed in front of the eye in such a fashion that parallel rays are artificially made divergent before they reach it. They will then not be brought to a focus too soon. Therefore, the short-sighted person uses spectacles with concave lenses, the measure of the concavity being proportional to his defect. As a rule, short-sightedness increases during the 'teens and for some time beyond. This lengthening of the eye from front to back may be put down to a normal tendency of its growth or to its introduction to long hours of positive accommodation, or to both factors; the last, perhaps, being the more important.

**Long-sightedness.** The simplest form of long-sightedness is that which we call *presbyopia*. It is a change in the eye which is not unwelcome to the short-sighted person, since it tends to neutralise his defect. We have already noted the age at which it occurs and its first symptom. The loss of elasticity of the lens is probably due to the same causes as its reduction in density. These two changes, between them, make positive accommodation difficult. In very old age the lens is so inelastic that, however much the suspensory ligament be relaxed by the effort of positive accommodation, the lens does not bulge at all.

The second form of long-sightedness, *hypermetropia*, is due to the opposite defect to that which causes myopia. Either the cornea is too flat or, as is the rule, the eyeball is too short from front to back, the consequence being that parallel rays are not focussed upon the retina in time. In order to effect this focussing, positive accommodation is necessary. Hence, positive accommodation is always necessary with the hypermetropic eye, whereas it is not in the presbyopic eye. It follows that the ciliary muscle is very much over-worked in, for instance, long-sighted children, the commonest consequence being headache. The difference between hypermetropia and presbyopia can be demonstrated by the use of the drug called atropine, which paralyses the ciliary muscle. If this be brought to bear upon a presbyopic eye, near objects are blurred, but not distant objects. But all objects are blurred for the hypermetropic eye which has been placed under the influence of atropine, since such an eye needs the use of its ciliary muscle for the proper focussing both of parallel and of divergent rays.

Plainly, the reason why the long-sighted person holds print at arm's length from the eye, is that he thereby makes the divergence of the rays as slight as possible.

Obviously, the manner in which to correct a defect which consists in not focussing the rays in time is to add a converging or convex lens

to those which the eye already possesses but which are insufficient to meet the demands made by the nearness of its retina to its crystalline lens. Again, the convexity must be proportioned to the shortness, that is to say, the long-sightedness, of the eye. The artificial lenses must be made extremely convex in cases where, owing to cataract, the crystalline lens of the eye has had to be removed altogether.

**"Near Point" and "Far Point" of Sight.** By the far point, or *punctum remotum*, is meant the most distant point seen without accommodation. There is a good deal of confusion in the use of these terms, however, and often the term *far point* is used in other ways. At any rate, the far point is brought nearer for the short-sighted eye, while for the long-sighted eye there is no far point at all—accommodation being always necessary. On the other hand, there is a limit to accommodation, and this is indicated by the near point, or *punctum proximum*. In the presbyopic eye the near point is removed, while the far point is unaffected. In the hypermetropic eye, both near point and far point are made more distant, while in the myopic eye, both are nearer. An extremely short-sighted person may be seen reading at distances so close that the print would be absolutely illegible to an emmetropic eye—being within its near point.

The cornea very frequently offers a special complexity to the act of vision by reason of its curvature not being equal in all directions. The resulting defect of vision is known as *astigmatism*. Such an eye cannot clearly focus at one and the same time the two limbs, horizontal and vertical, of a cross. The commonest form of this defect is that in which the cornea is more convex in the vertical direction than in the horizontal—in other words, the eye is short-sighted, or is more short-sighted, for the vertical limb of the cross than for the horizontal. Whatever the particular angle be, glasses can, however, be ground so as to compensate for the defect. If one suffers from the rare defect of pure astigmatism, one merely requires cylindrical lenses placed at the necessary angle. If, however, as is much more frequently the case, short-sightedness and astigmatism go together, compound lenses have to be ground so as to correct both defects. It is obvious that the curvature of the cylindrical lenses, added to that of the least convex meridian of the cornea, will make its focal length equal to that of the maximum meridian.

**The Constant Defects of the Eye.** There are certain constant defects of the eye of which Helmholtz was thinking when he made the remark which we have elsewhere quoted. We may note them without in any degree detracting from the wonder and admiration which the amazing powers of this organ must surely arouse in us. Charles Darwin, who showed how the evolution of the eye may be explained by natural processes, said that "he never could think of the eye without a cold shudder," so

insuperable at first seemed the difficulties of explaining its wonderful construction on his principles.

The defect of spherical aberration is not very serious, and is corrected, to a very large extent, in several ways. First, as we have already seen, the iris cuts off the outermost rays, and cuts off more of them when the rays are more divergent, and the consequences of not doing so would be more marked. Secondly, the curvatures of the two surfaces of the lens are not the same, but tend to correct one another in this respect. Thirdly, the lens is denser in its centre, as we have already seen, so that its refractive power is less at its circumference; and fourthly, the curvature of the cornea is not really spherical but is such that rays furthest from the axis are less deviated than they would be if the curvature were spherical.

**The Eye and Colour.** The eye is also somewhat defective on the score of chromatic aberration, though not nearly so much as it would be were it not that, as we have seen, some measure of achromatism is obtained by the use of media of dissimilar constitution. Says Prof. M'Kendrick: "... If, however, we look at a candle flame through a bit of cobalt blue glass, which transmits only the red and blue rays, the flame may appear violet surrounded by blue, or blue surrounded by violet, according as we have accommodated the eye for different distances. Red surfaces always appear nearer than violet surfaces situated in the same plane, because the eye has to be accommodated more for the red than for the violet, and consequently we imagine them to be nearer. Again, if we contemplate red letters or designs on a violet ground, the eye soon becomes fatigued, and the designs may appear to move."

**The Eye may See Itself.** If we merely consider the fact that the part of the eye which actually sees is practically the hindmost part, being not merely the retina, or curtain at the back of the eye, but practically the deepest layer of that curtain, we shall realise that, under certain conditions, the eye may see itself or parts of itself. It has already been noted that white blood corpuscles, wandering about in the vitreous humour, may cast appreciable shadows upon the retina. Shadows more serious, because permanent, may also be cast by, for instance, scars upon the cornea. The remarkable fact about all such phenomena is that the mind projects them into external space so that they are referred to the outside world; whereas, in reality, they exist in the eye itself. Far and away the most remarkable of these are due to the eye's perception, by means of the ninth or all but the deepest layer of the retina, of objects normal or abnormal, in the eight layers of the retina through which all light has to pass before it reaches the perceptive layer. Ignoring perception of opaque spots, which are abnormal in any part of the retina, we may consider the remarkable fact that, under certain conditions, the eye may become conscious of the blood-vessels that normally lie in the retina. If a strong beam of light be thrown upon the edge

of the sclerotic, or white of the eye, one is conscious of a curiously branched appearance which technically goes by the name of *Purkinje's figures*, and which is none other than an image of the retinal blood-vessels. Another experiment also suffices to reveal to the eye its own retinal blood-vessels. This consists of "looking at a strong light through a minute aperture, in front of which a rapid to-and-fro movement is made."

### Can we "See" Canals on Mars?

These experiments are of interest to the physiologist because they prove to him that it is practically the deepest layer of the retina, the last to be reached by the light, which is the really sensitive and essential part of it. But they are also of extraordinary interest to us as students of physics.

The reader is familiar with the so-called canals of Mars, which have given rise to so much controversy since their discovery by Schiaparelli. Doubtless, also, he has heard of what are called the N rays, asserted to be a new kind of ethereal vibrations and believed to have been discovered a year or two ago by M. Blondlot, of the University of Nancy, in France, from the first letter of which he derived their name. It is not our business here to discuss the canals of Mars beyond merely noting what the reader has doubtless heard, that their existence as an objective fact—whatever its interpretation—has lately been proved by the camera. They have been photographed. As for the N rays, to which we may have space to return, their case remains dubious. But the actual facts as to these two cases are not the present point.

### Does the Eye See What is not There?

The interesting matter for us is that the reality of both of these appearances has been questioned, and quite legitimately questioned, on grounds suggested by the physics of the eye. The common alternative, with which we are all familiar, as regards any appearance, is simply this—Does it correspond to a real existence in the outside world, or is it due to imagination? This applies, let us say, to the case of a ghost. Was there something "really there" which gave rise to the ghostly appearance, or was it a hallucination? To very few people has it occurred that there is a third possibility in certain cases. It may be that the eye really sees something which is really *somewhere* but is not really *there*. It is within the eye itself, but so persistently does the mind refer sensations of vision to the exterior world that the eye is deceived.

For instance, in the case of the canals of Mars, experiments made by a distinguished English astronomer, Mr. Maunders, showed that, whether or not these really exist, it is possible under certain conditions to produce appearances which may be mistaken for them. When schoolboys were set at sufficient distances from blank maps of Mars, on which they were told that canals were to be seen, very faintly marked, if only they looked carefully enough, they drew appearances which strongly suggested those figured by Schiaparelli. Other explanations are possible, perhaps, but the likeliest is that, by excessive

straining, these boys had gained faint impressions of the blood-vessels in their own retinae.

**Imagination and Sight.** Similarly, it was argued in the case of the astronomer, it entails considerable strain to look through a telescope for any length of time, and the argument was that the strained eye became hypersensitive so as to see and attribute to Mars images of the blood-vessels within itself. A similar train of argument applies to the N rays. The fact that in the case of the canals of Mars, at any rate, the objective character of the appearance has now been proved by other means, does not in the least detract from the importance of recognising the possibility of this error. Chiefly, perhaps, it is important from the point of view of the psychologist, but the physicist has to recognise it if he is not to make serious errors. After this explanation the reader will distinguish once and for all between (1) the results of imagination, so-called; (2) the results of vision of what is really external and appears to be so; and (3) the results of vision of what is really within the eye but, in consequence of the overwhelming preponderance of experience, is thought to be external.

### The Proper Light of the Retina.

In this phrase, as in a very large number of other scientific and philosophic phrases, the word *proper* has its *proper* meaning, with which the reader should be familiar. It is, of course, derived from the Latin *proprius*, and it means *own* or *proper to*. In defining the term we cannot do better than quote the words of Professor M'Kendrick, who is one of the chief students of the subject. He says: "The visual field, even when the eyelids are closed in a dark room, is not absolutely dark. There is a sensation of faint luminosity which may at one moment be brighter than at another. This is often termed the *proper light of the retina*, and it indicates a certain condition of molecular activity, even in darkness."

The recognition of this proper light of the retina will suffice to remind us of the all-important distinction between *light* and *vision*. On the one hand, there is abundance of light which cannot cause vision—that is to say, ethereal vibration just outside the octave which we happen to be able to see; while, on the other hand, there may be vision which is not caused by light.

**The Use of Two Eyes.** Constantly, as in the last paragraph, we find ourselves led to consider the retina—the ultimate fact of the eye—but we must leave this subject to the last. Meanwhile, we must note in its place a fact which has been carefully discussed in the course on Psychology. It was there shown that vision with two eyes, or binocular vision, gives us our impressions of depth or perspective or solidity. In discussing sound, we saw that the only value of having two ears, apart from having another to fall back upon if one be injured, is that they help us to appreciate the *direction* of sound. The possession of two eyes, however, gives us far more, since it gives an entirely new and distinct quality to our vision. This is absolutely true, notwithstanding the fact that long experience

with two eyes and with the other senses may enable us to obtain perceptions of depth as well as height and breadth, even with one eye only. If it is desired to prove how little value experience has when it comes to a test, let one try to thread a needle at a little distance with one eye shut.

If both eyes be equally strong, the perception which they give is not identical with the perception of either eye alone, but it is almost invariably the rule that one eye is stronger than the other, and that it is *its* image which we perceive.

### When One Thing Looks Like Two.

But let us consider what simultaneous vision with two eyes requires. Compare the case of trying to look at one's own nose with that of looking at a star. In the latter case there is practically no "optic angle"—that is to say, the angle formed by lines from the object through the centre of each of the two eyes. On the other hand, in looking at one's own nose there is a very large optic angle. The contrast between the two cases will suffice to show the extreme complexity of the arrangements which are necessary in order to enable us to obtain a simple image from two eyes. This possibility is explained by what is called the *theory of corresponding points*. For instance, if we look at a pencil with both eyes at once, we only see one pencil, but if we look past it we see two. This implies that, in the first case, the two images of the pencil fall upon "corresponding points" in the two eyes—*viz.*, the two yellow spots. But when we look past the pencil at something beyond it, the eyes which were formerly slightly converged or squinting, look more forwards and parallel with each other. The consequence is that the images from the pencil do not fall upon points of the two retinæ which correspond or are accustomed to act together. The accompanying diagram will readily explain this. The lines marked 1 indicate the manner in which, in the first position, the rays from the pencil fall upon corresponding points in the two eyes. But in the second position, when the eyes are looking at the window bar, the rays from the pencil will fall in the fashion of the dotted lines—that is to say, upon the outer parts of the two retinæ, which are not accustomed to act together. On the contrary, the left halves and the right halves of the two retinæ contain corresponding points.

**The Eye's Complex System of Muscles.** It follows from these considerations that the simultaneous movements of the two eyeballs in binocular vision, in order that two images of any object may fall upon the corresponding points in the two retinæ and may thus be perceived as one, require the most complicated nervous arrangements. In order to carry them out, each eyeball has six muscles,

each set of six being supplied by three nerves, and the whole being controlled from a centre in the brain. This co-ordinated movement is the most complicated known. It would require a page to describe its complexity in such a case as, for instance, looking at a pencil held close in front of the two eyes and then following it with both eyes while it passes to right or left. In such a case the eyes are convergent all the time, and as they pass to one side or the other, the one eye has to rotate through a much wider angle than its fellow in order that single perception may still result. The reader can easily draw for himself a diagram which will show this. Its successful accomplishment is one of the marvels of nerve physiology. Some kind of explanation of this possibility is furnished by the fact that while we can move one eyelid, we cannot move one eye. In other words, the movements of the two eyeballs are simultaneously controlled from one centre and are so interdependent that they cannot be made independent.

**How the Eye is Deceived.** The student of the course on Chemistry is already acquainted with the stereoscope, or *solid seer*. This is simply an apparatus by which one places side by side two photographs or drawings of one and the same object; that on the left being a representation of the object as seen by the left eye, and the right corresponding. If now we place an opaque partition in such a fashion that the right eye can see only the view on the right and the left similarly, we get a stereoscopic percept—we see the thing in relief.

Thus the eye is, of course, deceived, and there are many and familiar other means by which it can be shown how the eye is at the mercy of many external circumstances. Take, for instance, judgments of size. We have already seen that an object at twice the focal length of a lens has an image of the same size. At less than twice the focal length the image is enlarged; at more than twice the focal length it is smaller. The images of all the objects we see, except by the aid of the microscope, are smaller than the actual objects. Nevertheless, the eye is, so to speak, deceived into thinking that it sees things as large as they are. Similarly, it is deceived into thinking that it sees things upright, whereas all retinal images are inverted.

These, of course, are uses of the word *deceive* which we have deliberately made unusual. A more common use of the word may be employed in noting other visual judgments. Everyone is familiar with pairs of diagrams, such as those which we here reproduce, wherein two lines of exactly the same length are made to appear very unequal, merely in consequence of the way in which other lines are drawn from them.

# INSPIRATION

The Limitations of Mental Energy and the Value of Passiveness. The Unconscious Working of the Mind. Food for Mental Inspiration

Group 17  
**APPLIED  
EDUCATION**

11

Continued from  
page 2938

By HAROLD BEGBIE

**N**OTHING is of more vital importance to the success of the student's schemes and plans than the recognition of the limitation of mental energy.

By practice we can increase our power of hard reading, by an effort of will we can intensify and extend our faculty of attention, but there comes a time when the mind—the physical organism of the brain—rebels against such enforced labour, and all our painful reading is in vain.

The eye it cannot choose but see,  
We cannot bid the ear be still ;  
Our bodies feel, where'er they be,  
Against or with our will,  
Nor less I deem that there are powers  
Which of themselves our minds impress ;  
That we can feed this mind of ours  
In a wise passiveness.  
Think you, mid all this mighty sum  
Of things for ever speaking,  
That nothing of itself will come,  
But we must still be seeking ?

The value of this period of wise passiveness can scarcely be exaggerated. Wordsworth regards it as a time when we may feed our minds, and no doubt he is right ; but it is a time above all others when our minds can feed us. The consciousness of the individual in moments of great quiet and extreme passiveness will receive ideas and images of which either it had hitherto never been cognisant or cognisant only unintelligently.

**Subconscious Activity.** One of the mental processes of which we know least, but of which we are, perhaps, more assured than of any other, is the subconscious germination of ideas. It is the most perplexing, the most interesting, and the most suggestive of all the mental processes. There is a department of our mental machinery which takes over the ideas we toss to it or let slip from our fingers—even, too, the ideas which creep in unknown to us between the gates of consciousness—and, receiving them, does not merely hold them and retain them as a sensitive plate holds and retains the picture flashed upon it through the lens of a camera, but, rather, receives those ideas as the earth receives a seed or as an incubator receives an egg, and, all unconsciously to ourselves, broods upon those ideas and transforms them into other forms and fresh energies and powers.

Professor William James has said that we learn to swim in winter and to skate in summer, by which he means that having tried to skate through a single winter, and having progressed but indifferently, when we come to renew our efforts with the following winter we find to our amazement that we begin, not where we left

off, but in advance of everything that we had ever attempted before. A boy who has once learnt to swim never forgets the art, and, though practice be necessary to make him a good swimmer, and training to get him into "the pink of condition," still he is always a potentially better swimmer every time he enters the water, even though years elapse between his experiences.

**Its Bearing on Study.** It is to this secret working of the mind that the educator must bring his intelligence in considering his plan of conduct. Periods of rest from concentrated effort are not a passive good to him, they are an active good. He must cultivate them as assiduously as he cultivates concentration or will-power. He must accustom himself to remaining quiet and receiving from his subconscious self, or, as F. W. H. Myers would say, from his subliminal consciousness, more vivid images than his purely intuitive faculty can create or his most energetic reflection can supply. It is to these images he must look for his originality. The ideas presented to him "in a wise passiveness" are the fruit of his own personality, the colour of his own individuality, the express image of his own spirit. Originally he received the seed from another mind, or from the universal mind whence all intuitions proceed, but as they present themselves to him now they are not the seed but the flower from the soil of his own soul. Fragrant and life-giving herbs they may be, or poisonous and deadly weeds—whichever they are, they will be the fruit of his own growing. Whatsoever he sows that also shall he reap.

Let the educator, then, be warned, first, against what Huxley called "the educational abomination of desolation"—book-gluttony and lesson-bibbing. Even the hardest-worked of us all, he says, if he has to deal with anything above mere details, will do well, now and again, to let his brains lie fallow for a space. "*The next crop of thought will certainly be all the fuller in the ear, and the weeds fewer.*"

**The Value of Passiveness.** And, in the second place, the student must be warned against regarding periods of passiveness as wasted time. It is easier to frighten a man away from book-gluttony and lesson-bibbing than to convince him of the fruitfulness of a wise passiveness. But we hope to show that far from being a wasted time, a time of wise passiveness is just that period in which inspiration can best do its work—inspiration which is the flame of originality and the fire of genius.

Genius is defined by Myers in the famous third chapter of "Human Personality" as a power of utilizing a wider range than other men can

utilise of faculties in some degree innate in all, and an "inspiration of genius" as in truth a subliminal uprush, an emergence into the current of ideas which he has not consciously originated, but which have shaped themselves beyond his will, in profounder regions of his being.

R. L. Stevenson used to lie abed before sleep-time thinking of his stories, setting, as he said, "the brownies" to do his work for him. The part of the work done in sleep, he said, is the brownies' part beyond contention; "but that which is done when I am up and about is by no means necessarily mine, since all goes to show the brownies have a hand in it even then."

**The Secret Work of the Mind.** Beyond contention, indeed, is the fact that our brains work for us when we are idle, that our thoughts move faster when we are not behind them flogging their jaded energies with the whip of concentration. When Huxley said that the crop of thought, after a time of fallow, would certainly be all the fuller in the ear, and the weeds fewer, he stated what his readers believed to be a truth, but a truth the significance of which neither the people who subscribed to it nor the brilliant man of science himself thoroughly apprehended. Huxley was not a profound psychologist, and he was so devoted a physicist that he did not even stop to ask why a brain should know more after a period of rest than it knew before. Myers' great work was not then published, and, indeed, it is only of quite recent time that evidence has been accumulated sufficient to justify the thesis of that work. It is now, we advance, beyond contention that the mind's inspiration is received from the invisible germination of ideas in a "department" of the mind below the threshold of consciousness. It is proved, by experiments in hypnotism, and by everyday experience, where carefully observed, that the mind works in secret in bringing to perfection the ideas and images received by it with or without the knowledge of the consciousness.

**Food for Mental Inspiration.** This being so, the educator must inquire in which direction his talents lead him, and be careful to work as far as possible in that direction, since it is on that road more than on any other that inspiration is likely to shine for his feet. A man with a natural bias towards machinery should not hope to experience a musical inspiration or a military inspiration. He should not—if he is bent on pushing his fortunes—make a study of literature or a study of commerce. He should read deeply about machinery, and should converse with men profoundly conversant with machinery, and so in his moods of passiveness he will be likely to receive inspiration in the invention of machinery. To feed the mind on that which it demands—provided always the taste is sane and healthy—is to provide it with the material for inspiration.

It must always be remembered that these subliminal uprushes, or, as we say in the

language of the street, these happy thoughts, come almost invariably in moments when the consciousness is least busy. The man of iron will is seldom a creative genius, the brilliant administrator is seldom a man of ideas. The consciousness is kept so busy by these energetic minds that the brain never obtains a hearing. They may, indeed, become so immersed in their work that consciousness is practically in abeyance—that is to say, the consciousness is so intent as to shut off all the appeals which reach it through the avenues of sense—in which case the happy thought, the bright idea, may come to them. There are authors whose inspirations come during the moment of composition—whence, they know not, nor how; they have not dreamed the idea beforehand, they have not received it in periods of a wise passiveness, it has come to them when in the midst of work; their consciousness has been so intent that the striking of a clock has not reached their ears nor the opening of a door attracted their attention.

**The Spontaneity of Inspiration.** In this case, if we thoroughly understood the mechanism of the brain, we should probably find that consciousness was as much removed by its very intensity of concentration as it is removed in the hypnotic trance by gazing fixedly on a bright light. One thing at least is certain, and on this the educator should fasten his apprehension—no amount of brain cudgelling will ever bring forth a flash of genius. Not by any amount of hammering on the anvil of thought does the spark fly for which, like the scholar-gipsy, we all wait—the spark from heaven. Indeed, it is by striving and wrestling and overlonging that we drive it away from us, keep it afar off. It comes like a thief in the night, it comes when we are least prepared for it, it comes to us with a sudden uprush of vitality which makes us think that till then we have never seen nor heard nor lived. To receive it we must accustom our minds to periods of abstraction, but not periods of enforced and difficultly continued abstraction, not periods where effort and energy play any part. It requires no particular posture of repose, no studied and preconsidered arrangement of environment. Walking, or eating, or on the high seas, the idea may come for which we are waiting. All that is necessary is the gradual cultivation of ease in our consciousness, the occasional checking of that busybody and inquisitive spirit which keeps the consciousness of some unhappy people in a perpetual flurry and excitement. A man of science and a great inventor has said that his life is so busy that he has no time to receive inspiration except when he is dressing. Some people have their consciousness more vivid and alert before the mirror than in any other place, and for them ideas are not likely to come at such a time, if ever at all. But it is just in periods of this kind—simple periods in the day when we are doing things which have become more or less automatic with us—that we are most likely to receive the harvest of our hopes and labours.

# A LIMITED COMPANY'S ACCOUNTS

Formation of Company. Capital. Shares. Prospectus.  
Register of Members. Purchase of a Business

Group 7  
CLERKSHIP

22

Continued from  
page 2082

By J. F. G. PRICE

A LARGE and constantly increasing proportion of the business of the country is carried on by what are known as limited companies. Indeed, it is scarcely an exaggeration to say that the giant strides made by our commerce in the last half century would not have been possible without the assistance derived by private enterprise from the co-operation of the small capitalist by means of the facilities afforded by limited liability companies.

**Firms and Limited Companies.** Before we can proceed to deal with the accounts of limited companies, it is necessary that we should know something of what a limited company is. It has been seen that a partnership is a combination of two or more persons who have united their resources for the purpose of jointly carrying on a business for their common benefit. They are jointly and individually liable for the debts of the firm, and in the event of failure, are bound to contribute to the full extent of their private property, if necessary, to discharge the firm's indebtedness to outside persons.

In the case of a limited company, the proprietors, who are called shareholders, are only liable to be called upon to pay the debts of the company to the extent of the amount they agreed to contribute when they first joined the concern. In other words, their liability is limited, and the extent of the limitation is fixed by the shareholders themselves when they determine to become members of the company.

**Memorandum of Association.** A company is a number of persons combined into one body by law, so that the company has a distinct personality apart from the persons who compose it. It must consist of at least seven members, and if at any time the number should fall below seven, the company can be wound up. Every company must be registered at Somerset House with the Registrar of Joint Stock Companies, and the first step to be taken is for at least seven persons to sign a document known as the memorandum of association, which must contain certain particulars. Those particulars are: (1) the full name of the company in which "limited" must be the last word; (2) the part of the United Kingdom in which the registered office will be situated; (3) the objects of the company, which are stated very fully; (4) a statement that the liability of the members is limited; and (5) the amount of the capital of the company and the manner in which it is divided into shares. Each of the signatories to this document must agree to take at least one share in the company.

**Articles of Association.** With the memorandum it is usual to lodge a further document known as the articles of association, which contains the regulations for the carrying on of the company. The articles make provision for calls on shares, transfers of shares, meetings of the company, votes of members, accounts, audit, winding up, etc. If articles of association are not lodged the company is regulated by a model set provided by the Companies Act, 1862 [Table A]. It would manifestly be impossible for the business of a company to be conducted by the shareholders as a body, and the work is therefore delegated to a small number of persons who are called the directors. They are frequently appointed by the articles of association, which also regulate their powers, qualification, retirement, etc.

The memorandum and the articles (if any), and a separate statement of the capital, have to be left with the registrar, together with a declaration, usually made by a solicitor, that all the requirements of the Companies Acts have been complied with. Certain stamp duties have to be paid, increasing with the amount of the capital, and if the documents are regular, the registrar issues a certificate that the company has been incorporated.

**The Company's Capital.** Mention has been made of the company's capital and of the shares into which it is divided. Both these terms require further explanation, for the word capital has several different meanings in connection with a company, according to the sense in which it is employed, while there are various kinds of shares, each having different rights. The capital which is named in the memorandum of association is known as the *nominal capital* of the company, and is the maximum amount of shares the company is allowed to issue. The amount of the shares which the company has actually issued to applicants is known as the *subscribed and issued capital*. The amount which the shareholders have been required to pay upon the shares issued is the *called-up capital*, and the amount received by the company on the shares is the *paid-up capital*.

**Classes of Shares.** The nominal capital of a company is divided into a number of parts of fixed amount called *shares*, each of which has a distinctive number given to it. When there is only one class of shares they are called ordinary shares. When the capital is divided into two classes, they are usually *preference* and *ordinary* shares, the former entitling the holders to participate in the profits of the undertaking to a certain fixed limit before any distribution is

made to the ordinary shareholders. The limit is fixed by way of a percentage upon the amount paid up on the shares, which are known as five per cent. or six per cent. preference shares, or as the case may be.

When the preference shares have received their percentage, the ordinary shareholders are entitled to the remainder of the profits, provided there are no other classes of shares ranking behind them. Distributions may be made to the shareholders only out of profits actually earned, and such distributions are called dividends. There is sometimes a further class of shares, entitled *founders'* or *deferred* shares, which are usually few in number, and entitle the holders to a fixed proportion of the profits remaining, after paying a dividend at a certain rate upon the ordinary shares—frequently ten per cent.

**The Prospectus.** Many companies are formed for the purpose of purchasing as going concerns businesses which have previously been carried on by firms or individuals, and in order that the money required to pay the purchase price may be obtained, an invitation is generally made to the public to take shares in the new company. The invitation is contained in a document known as a *prospectus*, which has to be filed with the registrar. If the company is a large one, the prospectus is advertised in the Press, as well as being circulated by post to probable investors. It sets out the object with which the company has been formed, and, for the purpose of enabling recipients to form an opinion of the prospects of future success, information is given as to the value of the property to be taken over and as to the profits which have been earned in the past by the old proprietors. This information is usually given in the shape of valuations by experts, and certificates of profits by public accountants.

The prospectus further states the manner in which the shares will have to be paid for, which is usually a certain amount per share on applying for them, another amount on allotment, and further sums at stated intervals, until the full amount of the share has been paid. Part of the full amount may be left to be called up by the directors as the business of the company may require. The names and addresses of the officers of the company are also given, including those of the directors, bankers, auditors, solicitors, brokers, and secretary. Certain other particulars have to be given in order to comply with the requirements of the Companies Act, 1900; but although these are of the utmost importance from the legal point of view, they do not require further mention here.

**Application and Allotment.** Enclosed in the prospectus is a form of application for shares, which has to be filled in and signed by the intending investor. He then has to forward it to the company's bankers, with a remittance for the amount stated in the prospectus as being payable on the shares. The money will be retained by the banker, and the application form sent on by him to the company. The secretary makes a list of the applications, showing the

number of shares applied for, and a meeting of the directors is held to consider them. It is necessary for the directors to state in the prospectus the number of shares which must be applied for before they will issue any to the public, or, as it is termed, go to allotment.

If application has been received for the minimum number of shares, the directors proceed to allot them to the applicants in accordance with their applications—i.e., they pass a resolution apportioning to each applicant the number of shares for which he has applied. In order to make the allotment binding upon the shareholder, a notice called a letter of allotment is sent to each applicant, stating the terms upon which the allotment has been made, and requiring him to pay the further amount now due upon his shares. As the dates arrive upon which further instalments are payable, applications are made by the company to the shareholders for payment until either the full amount of the shares or the amount mentioned in the prospectus as payable within a given time has been called up.

**Entries in the Company's Books.** Having now described the machinery by which the capital of a limited company is brought into being, it is necessary to explain the entries requisite for recording the various transactions in the company's books. In the case of an individual there is, of course, no obligation from himself to the business to provide the money he actually puts in as capital, and if he decides, upon reflection, not to start the business or invest his money, he is not bound to do so.

But in the case of an applicant for shares, the position is different. As soon as the company has notified its acceptance of his offer to take shares, he becomes bound to the company for the full amount of the shares allotted to him. As we have seen, he may not have to pay the full amount at once, but the company has the right to call upon him to pay at some time, and he is at once a debtor for the amount payable on the shares in respect of the instalments due on application and allotment. Entries are therefore made, debiting the shareholders with the amount due from them on application and allotment, and crediting accounts opened in the general ledger, entitled application account and allotment account.

**Opening the Capital Account.** Separate accounts are not opened for each shareholder in the general ledger. A distinct book is kept for the accounts of the individual shareholders, which is entitled the share ledger, and is generally combined with another book which the company is required by law to keep—i.e., the register of members. The form of the combined book will be shown later; at present we will follow the entries to be made in the company's general accounts. Let us suppose that a company has received applications for, and has allotted, 1,000 shares of £10 each, upon which £1 per share is payable on application, £2 per share on allotment, and £2 per share one month after allotment, the remaining £5 per share not being required at present. The entries

necessary in the company's books are first passed through the journal preparatory to being recorded in the ledger, and would be as under:

**Register of Members and Share Ledger.** It is now necessary to ascertain how the accounts of the individual shareholders

|        |   |     |           |           |  |
|--------|---|-----|-----------|-----------|--|
| June 1 | Sundry Shareholders .. .. .   | Dr. | 1,000 0 0 |           |  |

|        | For amount payable on allotment for 1,000 shares at £2 per share              |     |           |           |  |
| July 7 | Sundry Shareholders .. .. .   | Dr. | 2,000 0 0 |           |  |
|        | To First Call Account .. .. .   |     |           | 2,000 0 0 |  |
|        | For amount payable one month after allotment, on 1,000 shares at £2 per share |     |           |           |  |

The entries would be posted to accounts in the ledger in the usual way.

The company will have received the full amount of the application money through its bankers; we will assume further that all the allotment money has been received, and that £1,900 of the first call is also received. These amounts will be entered on the debit side of the cash book and posted to the credit side of the sundry shareholders' account. Entries are then made in the journal closing the application, allotment, and first call accounts by transferring the balances to an account called the share capital account, which is the true capital account of the company and remains open in the ledger throughout the company's existence.

As a result of these various journal and cash book entries the accounts in the ledger will appear as shown below.

The balance to the credit of the share capital account represents the amount for the time being called up on the shares, while the debit balance on the sundry shareholders' account is the amount unpaid in respect of the calls which have been made.

are dealt with. As in the case of a private partnership, each proprietor has a capital account of his own, although, as a rule, the book in which the accounts are kept is treated as a statistical book and not as a book of account. It is found convenient to combine the register of members, containing certain particulars and which the company is required by law to keep, with the share ledger containing the cash account of each member in relation to his share holding. Every member is debited with the respective amounts payable on his shares and credited with all sums he pays in respect thereof. The register shows not only the number of shares he acquires and disposes of, but also their distinctive numbers. The totals of the amounts debited to the individual shareholders must naturally agree with the amounts debited to the sundry shareholders' account in the general ledger, and the totals of the sums credited as paid will agree with the credits on that account. This explanation will enable the reader to understand the entries appearing in the form shown on the next page.

The vendor sometimes agrees to take part of his purchase price in shares of the company, which are issued to him credited as being paid up—i.e., the company's liability to him for his property is set off against his liability to the company on the shares to the extent of the nominal value of the latter. When payment is made in this way the vendor is debited with the nominal value of the shares and the share capital account is credited. The result will be the closing of his account, as the payments in cash or shares being for the difference due to him will exactly balance the account. An account is opened for him in the share ledger, in which he will be shown as the holder of the shares allotted to him, credited with the full amount paid up.

To make these processes quite clear an example of the acquisition of a business will be taken. W. Brown, a tailor, after having carried on business successfully for some years, decides to retire and dispose of his business to a limited company. His assets consist of his freehold shop and premises valued at £4,500; stock-in-trade, £500; book debts, £3,000; cash at bank and in hand, £350. His liabilities are, on bills payable £280, and on open accounts £420, leaving as his capital £7,650. The company takes over all the assets except the cash, and undertakes to discharge the liabilities. The excess of the assets acquired over the liabilities assumed is, therefore, £7,300. The price required by Brown is £9,000, the difference being the amount charged by him for goodwill. He agrees to accept payment of this price, £6,000 in cash and £3,000 in shares. The journal entries necessary to record the transfer and payment are as follows:

The order of the liabilities as given in the form is (1) the capital, showing the number of shares and the amount per share paid, with particulars of any arrears and forfeited shares; (2) the debts and liabilities, showing loans on mortgages or debenture bonds, debts on bills, open accounts and for interest, and also any amounts due to shareholders for unclaimed dividends; (3) any reserve funds; (4) the balance of the profit and loss account available for dividend; and (5) any contingent liabilities, being either claims not acknowledged as debts or amounts for which the company is only contingently liable.

The order of the assets is: (1) property held by the company, showing (a) immovable property, distinguishing freehold and leasehold land and buildings; and (b) movable property, distinguishing stock, plant, etc., and giving both cost and deductions for depreciation; (2) debts owing to the company, showing those considered good for which the company (a) holds bills or (b) has

Brown will also be debited and cash credited with the £6,000 payable in cash as and when the amount is paid. The student should now open the ledger accounts and post thereto the various journal and cash book entries in order that the full effect of the transactions may be appreciated.

**Companies' Balance - Sheets.** The assets and liabilities of limited companies are not, as a rule, arranged in the same order in the balance sheet as those of an individual or a firm. Table A of the Companies' Act, 1862, besides providing a model set of regulations for a company, also gives a form of balance-sheet to be used by companies governed by those regulations; and the order there laid down is very generally adopted by companies having articles of association of their own.

no security, and those considered doubtful or bad (any debt due by an officer of the company must be separately stated); (3) cash and investments, showing the nature of the investments and the whereabouts of the cash.

**Companies' Profits.** One point that emerges from the foregoing is that the balance of the profit and loss account is not transferred to the capital account, but is shown separately and distinctly in the balance-sheet. This is always necessary in the case of a company, whatever has been the result of the trading. If there has been a loss the balance will appear on the assets side of the balance-sheet. The disposal of the profit is usually shown in the ledger in an account called the Appropriation of Profit Account, a specimen of which, with the balance-sheet of a company, is given later.

# MAKING A MINE

Various Methods of Attacking Hidden Deposits. Shafts and Levels.  
Petroleum Wells. Pillar and Stall Work. Timbering and Stopping

By D. A. LOUIS

THE transition stage for open-cast to underground working is shown by diagram in 55. The first and second terraces have been worked open-cast, but the tunnel has been driven in at the level of the third terrace to expedite the transference of the ore to the railway.

**Bell Pits.** The bell pit is perhaps the simplest, and, at all events, the least pretentious of underground workings; it is applicable only to shallow deposits not deeper than 50 ft. or so, with good solid strata or beds above. It is an ancient and primitive method of working, but under some circumstances should by

no means be despised. A shaft as small in size as is feasible is sunk, and is widened out at the bottom to as large an extent as is consistent with safety. A *windlass* or a *whip*, or *whipsyerry*, erected at the top of the shaft, suffices for drawing up the rock and mineral in ordinary buckets or the larger mining bucket or *kibble*.

In the case of the whipsyerry, the rope from a pulley in the head-gear, instead of being wound on and off a windlass, passes under a pulley on the ground, and is hitched to a horse, the load being raised or lowered by walking the horse away from or towards the shaft. When the deposit is worked away as far as safety permits, the pit is abandoned. One or several pits may be at work at the same time, but between adjoining

workings a wall of unworked deposit is left to support the roof and to prevent the pit collapsing.

**Hand Dug Petroleum Wells.** Shallow deposits of petroleum are, in some localities, worked by means of shafts, and men go down these and fill buckets with the oil, which is drawn to the surface by windlass or whim. And odd-looking figures the men look when they come up reeking with oil. Fig. 58 represents a scene witnessed by the writer in

Roumania, from a photograph by Dr. Dvorkovitz. The position of the wells is indicated by the bellows used to supply the men with air, and by the horse whim used for drawing up the buckets of oil. Alongside each well is a covered circular tank into which the oil is run from the buckets. Two of these tanks are shown at the centre of the picture, with people standing on the cover.

## The Horse Whim.

The horse whim consists of a drum or short wooden cylinder, upon which the rope from the shaft winds. This drum has a vertical shaft working in a foot piece on the ground and supported above by a transverse beam raised on standards at each end. A crosspiece extends horizontally from the shaft below the drum and forms two arms, to one of which the horse is attached, the rope making a few turns round the drum. The horse is driven in one direction until one bucket is lowered to the bottom and the other raised to the surface; and then, by reversing this course, the latter bucket, having been emptied at the tank, is made to descend, while the other, which has been filled below, is drawn up.

## Petroleum Wells.

Usually, however, with petroleum a borehole suffices for the extraction of the oil, and, in fact, the oil rises in the borehole in most instances and discharges itself at the surface. This occasionally happens with great violence, and the petroleum is projected many feet in a great jet, sometimes even wrecking the whole derrick and plant. This appearance of petroleum is known as a *spouter* or *fountain*. When oil does not

55. TRANSITION FROM OPEN-CAST TO UNDERGROUND WORKING

56. DAY LEVEL, FULLERS' EARTH MINE AT MIDFORD, NEAR BATH  
Photograph by the Geological Survey

rise of its own accord in a petroleum well and where conditions are suitable, as they are in Canada, Pennsylvania, and Galicia, for instance, the oil is extracted by means of pumps. When conditions do not permit of the use of pumps, as at Baku, in Russia, where sand accompanies the oil and would interfere with the valves of pumps, bailing is resorted to. That is, long narrow buckets, attached to a rope run down the borehole into the oil, are allowed to fill, and are then wound up again and emptied at the surface, to be let down and refilled, and so on.

**Longwall and Pillar-and-stall Working.** Such simple methods as these can, however, rarely be adopted advantageously, and to work a deposit by underground methods entails a well-considered and systematic plan of operations which requires adaptation to suit each particular case, and is based on certain general and well-defined principles. For instance, if the deposit be more or less horizontal, it will be approached by a shaft, or two shafts, and will be worked away by driving large passages in the deposit, which may then be removed in long slices or cuts, similar to the long cuts or slices removed in working the iron ore in Lincolnshire already mentioned.

Or the deposit may, perhaps, be better worked by making comparatively short and narrow cuts, leaving blocks unworked to support the roof, such as the system seen in the limestone workings near Dudley, or in the Beer stone

57. PILLAR AND STALL WORKINGS IN SAND

Photograph by the Geologist's Association

quarries, or the Chislehurst chalk caves. Even sand may be worked in this way; the photograph [57], by Miss Mary Johnston, shows workings of this description in the Lower Greensand beds at Godstone, in Surrey. It is remarkable that, although the bed is quite loose silver sand when disturbed, yet the pillars are quite sufficient to support the workings. The former system is known as *longwall* working; the latter system as *pillar-and-stall* working. These systems are employed mostly for working bedded deposits, but some veins and masses are worked to advantage by these methods.

58. HAND DUG OIL WELLS, BISTENARI, ROUMANIA

59. TIMBER AND STEEL SUPPORTS IN A LEVEL.

**Vein Mining.** When, however, a deposit is steeply inclined, or vertical, a shaft for working may occasionally be sunk in the deposit itself, and side passages or *levels* driven from it at convenient depths apart in the deposit itself, which is then worked by removing from overhead, termed *overhand stoping*, or by digging it away from under foot, termed *underhand stoping*. In this class of mining, it is frequently better to sink the shaft in firm ground to the dip of the vein, so that the latter will be intercepted at some specified depth. Then passages, known as *cross-cuts*, are driven through the country to meet at right angles the veins, which are worked by the passages in or alongside the vein or levels and stopes as in the previous case. Veins generally, and many tilted bedded deposits occasionally, are worked by shafts, levels, and stoping.

#### Adits and Day Levels.

Whenever it is possible to do so, the deposit would be preferably worked by an *adit* or *day level*—that is, a passage driven from the open air either on the deposit itself or as a cross-cut to meet the deposit at right angles. The latter practice is generally preferable, as it ensures the strong level being in country, and also serves to explore any parallel veins. Adit mining, however, can be appropriately adopted only in hilly

or mountainous regions where there is a considerable extent of the deposit above the point where the day level would be driven. This is frequently the case, and day-level or tunnel working should be used wherever these suitable conditions obtain. It is more economical than shaft mining, inasmuch as, instead of having to raise the ore from the mine by machinery, with a possible considerable outlay for power, the ore from above reaches the day level by gravity, and has simply to be trammed or otherwise got along the day level to the open air. When the day level serves to drain the mine, it is called an *adit*, and saves the expense of pumping in the area above it. But even in the case of an adit a vertical shaft would be sunk from the surface above to meet it at its inner end, so as to create a current of air for ventilation, and as a supplementary means of access to the mine, which can be useful in various ways.

**Driving the Adit.** The *adit* would be driven in the same way as the costeaning drifts already described, but of a larger size, as it would probably be the main outlet. It would be carefully timbered where required, and would be given a slight but regular fall towards the mouth, so as to allow water to flow out and to have the grade in favour of the heavier full waggons. Fig. 59, from a photograph by Mr. Williams, illustrates two modes of supporting a gallery all round; immediately in front the supports are of timber, while at the back they take the form of steel rail arches.

The day level may, however, be comparatively insignificant, as, for instance, at the fullers' earth mines near Bath [56], where small work serves the purpose quite well. These workings are very closely timbered; some of the timbers may be seen projecting at the mouth of the adit. On the other hand, where operations are conducted on a more extensive scale the adit is given commensurate dimensions; Fig. 60, for instance, represents an entrance to an iron ore

60. DAY LEVEL, GRANGESBERG IRON ORE MINE, SWEDEN

mine in Sweden, where a large and heavy output has to be maintained, and the adit is in consequence quite a dignified tunnel.

It is extremely desirable to have the main artery as secure as possible, whether it be shaft or level.

**The Shaft.** The position of a shaft for *vein mining* would be determined by the preliminary investigations. The site would be selected so that as great a part of the mining as possible could be done with a minimum amount of cross-cutting. Vertical shafts are generally preferred because they are easier to sink, and they are more convenient for winding both men and material, as well as being better adapted for pumping purposes. There is a fascination in following the downward course of a lode by an inclined shaft, inasmuch as it gives some information about the character of the vein all the while the sinking is progressing; but this generally proves a poor recompense for the subsequent inconvenience. Moreover, the ground in the vein is rarely as reliable as the country, which is a very great consideration with such an important piece of work as a shaft.

In metal mining the shaft is usually rectangular, and is made of sufficient size to allow the proposed output to pass, to accommodate pumping rods, and to provide a ladderway; 10 ft. by 7 ft. is an average dimension. When the size and position of the shaft have been decided and the character of the ground does not provide room for depositing waste, or where there is danger from flooding, the mouth of the shaft is raised above the surrounding level. The shaft is sunk in the same way as the costeaning pit, but with more care, especially in the timbering and in ensuring verticality.

**Timbering the Shaft.** The timbering usually takes the form of frames of square timber, consisting of two larger pieces called *wall-plates* [63a] and two shorter ones called

*end-pieces* [63b],

joined by halving the timber at each end. The separate frames, when required, are kept apart by the introduction of distances or

*studdles* [63d], and where there is danger of loose ground falling in, *lagging* of boards [63, c, e], called *backing deals*, or of poles or small wood is packed behind the frames. And as occasion demands, corner-pieces are nailed in to keep the frames in position; and lashing deals, nailed inside from frame to frame, are employed when it is desired to bind them all together until properly supported. The frames are put nearer together if the ground is looser, and, at the top of the shaft, are frequently set continuous [61].

When the shaft is divided into compartments, timbers called *buntons*, or *dividers*, are fixed across the shaft parallel to the end-pieces. Planks or *casing-boards* are nailed to the buntons to form a continuous partition; the buntons also carry the cage guides and assist in supporting the ladder

platforms. The timbering is supported in the shaft by special brackets or *bearers*. In some cases the end-pieces are made long enough to project beyond the wall-plates and rest in niches in the rock.

Plats are excavated in the side of the shaft to provide retiring places for men during blasting operations while sinking is in progress. They serve, subsequently, as places for ore bins when working with a skip.

**Levels or Cross-cuts.** To connect the shaft with the deposit to be worked, galleries are driven out from it at distances varying from 50 ft. to 100 ft. apart. Fig. 62 shows galleries branching from each side of a shaft and a mode of timbering. If these are driven in the country they are called *cross-cuts*, and it in the vein, *levels*; they are secured by timbering as circumstances demand, are slightly graded, the fall being towards the shaft, while a gutter is provided to carry away any water; 6 ft. to 7 ft. by 4½ ft. wide is an ordinary size for a level; 7 ft. high by 6 ft., 7 ft., or more wide is a large size, but it is well to have plenty of room, to facilitate tramming and ventilation. Photograph 64 was taken in Foxdale lead mine, in the Isle of Man. It shows lead miners at work.

61. CLOSE TIMBERING IN A SHAFT

62. INTERSECTION OF SHAFT AND LEVELS

63. TIMBER SHAFT SUPPORTS

## MINING

and one side of the drift is firm rock and requires no support. Notice also the picks, drills, hammer, shovel, wheelbarrow. Fig. 65 shows a mode of supporting levels used in the Transvaal.

**Winzes.** Small connecting shafts are *sunk* or driven upwards, or *raised* from one level to another, for the purpose of ventilation and also to facilitate the handling of the ore and to break the vein into convenient blocks for working. When driven upwards the work is called a *raise* or *rise*, when sunk, a *winze*; but the completed work is usually called a winze, however made.

**Development.** Shaft sinking, cross-cutting, level driving, making raises or winzes, excavating adits—all these operations are known as *dead-work*, or development work. And except when any of this work is done on the vein, development work does not yield ore, but thorough development is one of the most important factors in good mining practice. For not alone should a good lot of ground be opened up or *laid open* ready for the removal of ore or *productive work* before these latter operations are started, but even when the mine is in full swing development work should be kept well ahead of the productive work. A good example of development work being done at a profit, which, however, very rarely happens, came within the writer's experience when a shaft was sunk 600 ft. in a lead vein to connect with an adit; the ore excavated in making the shaft more than paid for the whole work.

**Productive Work in Vein Mining.** This should be started only when the development work is well advanced, when plenty of ore has been blocked out by levels and winzes,

64. LEAD MINERS AT WORK. FOXDALE MINE, ISLE OF MAN

floor of the level to the depth of a few feet and trammings the material away, when the excavation is about three times as long as it is deep; it is deepened by sinking another hole at the centre and following on by attacking the material on each side of this hole. The excavation at the top is then enlarged by cutting away a block of ground at each end. The hole at the centre is next deepened another stage, and so the work goes on, removing blocks from the top and each succeeding stage in descending order, always deepening the centre hole in its turn. The excavation very soon looks like two rough kinds of staircases, meeting at the bottom, each stage or step being a few feet deep. The excavation is done by pick and shovel, wedge, or gad, and hammer, or drilling and blasting, just as the character of the ground demands; and to deal with the material excavated timber platforms called *stulls* are erected, and upon these the worthless stuff, *attle*, is thrown, while a windlass and buckets serve for

drawing up the ore to the level, to be trammed to the shaft and wound to surface. When the excavation reaches the level below, *hoppers* or *shoots* are put in, and into these the ore is charged, and the trouble and expense of winding to the level above is saved. For this reason, too, an underhand stope can be advantageously worked at the side of a winze, for then the ore is allowed to fall down the winze to the level below.

65. STONE WALL AND TIMBER SUPPORTS IN THE TRANSVAAL

and when there are plenty of *backs*—that is, ore above the levels; then, and then only, should the actual winning of the ore or *stopping* be started. This is done either by digging out the ore below the level—that is, by *underhand stopping*—or by taking it out from overhead—that is, by *overhand stopping*.

**Underhand Stopping.** Underhand stopping is commenced by digging a hole in the

Clerical, Engineering, and Surveying Posts in the Army  
and Navy Department's. The Coastguard Service

Group 6  
**CIVIL  
SERVICE**

22

NATIONAL SERVICE  
Continued from  
Page 2595

By ERNEST A. CARR

**Appointments for Junior Clerks.** The vacancies on the junior staff of the Admiralty Supply and Accounting Departments, the Royal Ordnance Factories, and the Army Accounts branch of the War Office, are filled by means of joint open competitions, to which all candidates between the ages of 18 and 20 are admissible. Examinerships in the Exchequer and Audit Office are also offered at the same contests, but for the present we are interested only in the Admiralty and War Office appointments. It should be noted that the age limits are extended in favour of persons who have served in the Army, Navy, Royal Irish Constabulary, or Civil Service. Competitors are allowed to enter for any post for which they are eligible, and, if successful, to choose among existing vacancies in the various offices named, according to their position on the combined pass list. The examination fee has very recently been reduced from £6 to £3.

So far, at least, as the two "fighting departments" are concerned, these situations should be distinctly attractive to any well-educated youth whose ambitions extend beyond the Second Division or Exeise but who cannot afford the special training needed in order to win a first-grade position. They offer both a very fair salary and excellent prospects of promotion. Except in the Ordnance Factories, the holders of junior appointments escape the monotony of ordinary office life by changes of station and a considerable spell of foreign service. Few clerks, indeed, on the home Civil Service staff are as fortunate in this respect.

These officers are all appointed at a uniform scale of pay. For the first two years they are on probation at a fixed salary of £100. It is then raised to £120, and progresses by £10 yearly to £200, and afterwards by £15 to a maximum of £350. But that figure does not by any means represent the average value of such appointments, for there are many higher staff positions attainable, with salaries ranging up to £800 or more, and valuable allowances in addition.

**The Naval Service.** Under the Admiralty, most of these higher positions are at the dockyards and naval stations at home and abroad. All officers serving abroad are granted local allowances, and either a house or a further allowance instead. It is the practice of the authorities to limit the term of foreign service to about 12 years, of which some five years may be spent at tropical stations, and the remainder in temperate climates. As officers are rarely kept at one station more than three years in the tropics or five years elsewhere, their service abroad is pleasantly varied.

The possibilities of the Admiralty service are best illustrated by official figures. In a total staff of 187, exactly 100 posts carry a maximum salary of at least £500 a year, and of this number 26 are remunerated with £700 or upwards, irrespective of allowances.

**War Office Posts.** Successful candidates who elect to enter the Army Accounts Department are appointed on the express understanding that they are liable to serve either at the War Office or at any station at home or abroad where our troops may be serving. Changes of station are, in fact, frequent, but foreign service seldom extends beyond a few years—seven at most—and is rewarded with extra allowances to cover the increased cost of living abroad. Officers are appointed in the first instance as Assistant Accountants of the second class, but those who show aptitude for their duties are eligible for promotion to the first class and to higher positions. As a further encouragement to men of ability, there is a provision that officials of at least five years' service in the department may have their salary specially raised to £215 a year. The staff of the Army Accounts branch is constituted as follows:

|     |                     |
|-----|---------------------|
| 228 | £100 to £350        |
| 140 | £350 — £15 — £500   |
| 55  | £550 — £20 — £700   |
| 2   | £850                |
| 14  | £850 — £50 — £1,000 |
| 439 |                     |

Appointments in the Royal Ordnance Factories are far fewer in number, and do not involve foreign service, officers being attached to Woolwich, Waltham Abbey, Enfield Lock, or Birmingham, as the needs of the service require. They have assured prospects of at least £500 a year, with chances of £700 or more; but this branch of the service does not afford as much scope as the accountancy section already discussed. A competitor who succeeds in taking a high place on the combined list would therefore be well advised (if he has no objection to foreign service) to select the Admiralty as a career, and in default the Army Accounts, in preference to the Ordnance Factories.

**The Competitions.** Candidates are at liberty to take up all the first five in the following list of subjects, and any two of the remainder. Of course, no one would have the smallest chance of success who offered less than the maximum number permitted. Failure in arithmetic or composition disqualifies for an appointment. A detailed syllabus, setting out the precise scope

## CIVIL SERVICE

and character of the examination in each subject, may be obtained from the Civil Service Commission.

1. Mathematics I. — Arithmetic, geometry (Euclid I. to VI., or work equivalent in scope), algebra, simple trigonometry, dynamics, and statics, with graphs and practical work.

2. Latin, with either Latin verse or Roman literature.

3. French or German, including conversation and writing a letter or essay in the language.

4. English composition and précis writing, and the reproduction of a passage read out.

5. Geography.

6. Mathematics II.—Solid and co-ordinate geometry, the calculus, etc., with a practical paper.

7. The modern language not taken under heading 3.

8. Greek.

9. History.—English, and a special period in European history.

10. Experimental science (physics and chemistry), with simple practical work in each section.

In the last subject, 75 per cent. of the total marks may be gained by a thorough knowledge of *either* branch.

### Engineering and Surveying Posts.

Candidates for the somewhat valuable position of assistant civil engineer in the Admiralty must be between 23 and 28 years of age, and must satisfy the authorities that they are qualified in respect of technical education and practical training. On the latter point the standard prescribed is at least three years' satisfactory service with a civil engineer or architect in good general practice, or a leading engineer in the dockyards or the Army. Except in English composition, the examination scheme is wholly technical. It includes mathematics and applied mechanics, surveying, hydraulic and sanitary engineering, drawing-office work, specifications, quantities, and estimates. On appointment, these officers receive £200 a year, rising to £300. When made Admiralty civil engineers, they start at the latter figure and advance to at least £550, with a house allowance, and with further prospects up to £1,200. The civil staff of the War Office includes a few professional posts corresponding generally with the Admiralty appointments.

The nomination of the First Lord, coupled with an examination similar to that prescribed for engineering posts, but less searching in its scope, admits trained men between the ages of 21 and 30 to the grade of assistant surveyor to the Admiralty. They begin at £150 a year, with a maximum of £400 as assistants and £600 as surveyors; and for them, as for their engineer colleagues, there are considerably higher posi-

tions within reach. For the special regulations framed for each of these classes of appointment application should be made to the department concerned.

**Assistant Clerks in the Navy.** Youths who covet a sea life but have not been able to undergo the long, expensive training exacted of budding naval officers, should turn their attention to the limited competitions for assistant clerkships in the Navy, admitting to the well-paid and attractive calling of naval paymaster. Probably because the advantages of this service are not as well known as they deserve to be, the competition for vacancies is not very severe; and the entrance examination offers no serious obstacle to a well-educated lad with a fair knowledge either of three foreign languages or of two languages and the elements of natural science.

Many would-be competitors are discouraged from entering by the fact that a nomination is requisite for these appointments. But this difficulty is more apparent than real, as private influence with the naval authorities is not imperative to secure the right to compete. A nomination by the First Lord of the Admiralty is readily granted to suitable candidates. Application should be made to his private secretary as soon as the lad for whom it is sought reaches the age of 16. The contests, which have hitherto taken place half-yearly, will in future be held each June—probably for about 40 vacancies—and candidates must be between 17 and 18 years old on the 15th of the following July. They must also be well developed and active for their age, and physically suited in all respects for service in the Navy. Short sight will not necessarily disqualify those who are otherwise fit.

The character of the entrance examination is shown by our schedule of subjects and marks, which relates to a competition for 19 places lately attended by 47 aspirants.

| EXAMINATION FOR ASSISTANT CLERKS IN THE NAVY |             |              |  |                                |              |         |                                    |        |                     |                   |

|  |             |              |  |                                |              |         |                                    |        |                     | TOTAL.            |
|  |             |              |  |                                |              |         |                                    |        |                     | 4,000             |
|  |             |              |  |                                |              |         |                                    |        |                     | 2,891             |
|  |             |              |  |                                |              |         |                                    |        |                     | 2,143             |

A note may be added on these subjects. Mathematics consists of algebra, geometry, and trigonometry; the test in English includes précis and shorthand (the latter being of special importance); and the English history paper has particular reference to the period since 1485. In modern languages special attention is given to the oral examination, and the language

not offered as obligatory may be taken as an optional subject. The science papers relate to mechanics, heat, physics, and inorganic chemistry, and include practical tests.

Successful candidates are appointed as assistant clerks at 2s. 6d. a day, and while in that grade must be furnished by their parents or guardians with an allowance of £20 a year. After a year's service, and on passing a further examination, they are rated as clerks at 4s. a day. Their further prospects may be judged from official statistics of the Service.

| No. | Grade.               | Pay.        |            |                                 |

| 41  | Assistant Clerks ..  | 2/6         | £45 12 6   | Some with temporary allowances. |
| 90  | Clerks .. .. .       | 4/-         | £73 0 0    |                                 |
|     |                      |             | £91 5 0    |                                 |
| 229 | Assistant Paymasters | 5/- to 11/6 | to         |                                 |
|     |                      |             | £200 17 6  |                                 |
| 257 | Paymasters (in 1     | 11/- to     | £255 10 0  |                                 |
|     | three classes) . . . | 33/-        | to         |                                 |
|     |                      |             | £302 5 0   |                                 |
| 12  | Paymasters-in-Chief  | 38/-        | £303 10 0  |                                 |

These figures show that speedy promotion is assured, at least to the grade of junior paymaster, for an officer whose conduct and abilities are satisfactory. And the rates of pay are high enough to render him self-supporting after the first year of his sea service—a great advantage to candidates whose relatives are not wealthy.

It need only be added that the sea life is a pleasant and varied one, and that the paymaster's post is generally regarded as the easiest berth in the ship.

**Writers and Others.** The clerical staff of the Admiralty includes a number of subordinate officers known as writers, and employed both afloat and ashore. Their ranks are recruited in part from applicants trained for the Service at Greenwich Schools, partly by competitive examinations in simple English subjects, shorthand, and typewriting, held half-yearly at the chief naval posts.

Candidates must be between 18 and 23 years of age, and at least 5 ft. 5 in. in height and 32 in. round the chest. In the Fleet they receive 2s. a day on appointment, rising to 6s., with free rations. The dockyard rates begin at 4s. a day, and candidates who display aptitude for the work may obtain higher-grade posts, in which their pay may rise to a maximum of 11s. daily.

Executive posts in the fleets and naval bases—such as are obtained, for example, by means of the examinations for boy artificers and dockyard apprentices—are considered part of the Navy proper, and will therefore be discussed in the section on that subject which is to succeed the present course. For our purpose, the Civil side of the Admiralty may be completed by a few words on the conditions of entry and rates of pay which obtain in the Coastguard Service.

**Coastguard Service.** Seamen of good character who have completed nine years' continuous service, and are recommended by their captains, are eligible for admission to the Coastguard under the following conditions. They must be trained men or holders of a torpedo or gunnery rating, not over 37 years of age, able to swim and to read and write, and willing to re-engage, if necessary, for continuous service to complete their time for a pension. A limited number of stokers of eight years' service are also admitted, and carpenters who have served for ten years in the Fleet with "very good" character may be appointed as divisional carpenters in the Coastguard.

Coastguard men are liable to be embarked in turn for such cruises as the Admiralty may appoint, and if found unfit for active service at sea may be discharged with a pension or gratuity, according to the length of their service. Otherwise they are retained until the age of 50, or, in the case of chief boatmen-in-charge, until 55, when they retire on a life pension.

Apart from the commissioned officers, who number only 103, the strength, ratings, pay, and allowances of the Coastguard Service are as stated in the table on this page. Modest as are the rates of pay in themselves, it must be

| RATES OF PAY AND ALLOWANCES FOR COASTGUARD SERVICE |                             |      |       |                      |                         |
|--|-----------------------------|------|-------|----------------------|-------------------------|
| No.  | Rating.                     | Pay. |       | Provision Allowance. | Other Emoluments.       |

| 4019   | Chief Boatmen               | 39   | 10 10 |                      | £1 11s. 3d. Tool Money. |
|  | .. after 4 years            | 14   | 2 1   |                      |                         |
|  | Commissioned Boatmen        | 31   | 18 0  |                      |                         |
|  | Boatmen                     | 28   | 17 11 |                      |                         |
| 4206   | Divisional Carpenters       | 50   | 3 9   |                      |                         |

Good Conduct Badges, 1d. a day for each badge. All except Divisional Carpenters, 1d. a day when qualified as Trained Men.

remembered that the provision of free quarters is a valuable one, and that with this advantage and a liberal allowance for rations, the coastguard's needs are small.

## FRACTIONS &amp; QUADRATIC EQUATIONS

Division of Fractions. Reduction of Compound Fractions. Equations with Fractions. Definition of and Methods of Solving Quadratic Equations

By HERBERT J. ALLPORT, M.A.

## FRACTIONS—continued

87. Division of Fractions. Let  $\frac{a}{b}$  and

$\frac{c}{d}$  be two fractions, and let  $x$  denote the quotient  $\frac{a}{b} \div \frac{c}{d}$ . Then

$$x \times \frac{c}{d} = \frac{a}{b} \div \frac{c}{d} \times \frac{c}{d}.$$

But, if we divide  $\frac{a}{b}$  by any quantity and then multiply the quotient by the same quantity, it is clear that the result is  $\frac{a}{b}$ . Thus

$$x \times \frac{c}{d} = \frac{a}{b}.$$

Therefore,  $x \times \frac{c}{d} \times \frac{d}{c} = \frac{a}{b} \times \frac{d}{c}$ .

But  $x \times \frac{c}{d} \times \frac{d}{c} = x \times 1 = x$ . [Art. 83.]

Hence,  $x = \frac{a}{b} \times \frac{d}{c}$ .

That is, *to divide one fraction by another, invert the divisor, and proceed as in multiplication.*

88. Both in multiplication and division we must, of course, reduce the result to its lowest terms by cancelling common factors of the numerator and denominator.

Example 1. Simplify

$$\frac{x^2 + xy}{x^3 - x^2y} \times \frac{x^4 - x^3y}{x + y}.$$

We resolve the numerators and denominators into factors, and cancel those which are common to the numerator and denominator of the product. Thus

$$\begin{aligned} & \frac{x^2 + xy}{x^3 - x^2y} \times \frac{x^4 - x^3y}{x + y} \\ &= \frac{x(x + y)}{x^2(x - y)} \times \frac{x^3(x - y)}{(x + y)} \\ &= \frac{x^2 \text{ Ans.}}{x^2} \end{aligned}$$

Example 2. Simplify

$$\left( \frac{x-2}{2x-3} - \frac{4x-5}{5x-6} \right) \div \left( \frac{2x-3}{3x-4} - \frac{3x-4}{4x-5} \right).$$

The given expression

$$\begin{aligned} &= \frac{(x-2)(5x-6) - (4x-5)(2x-3)}{(2x-3)(5x-6)} \div \frac{(2x-3)(4x-5) - (3x-4)(4x-5)}{(3x-4)(4x-5)} \\ &= \frac{5x^2 - 16x + 12 - 8x^2 + 22x - 15}{(2x-3)(5x-6)} \div \frac{8x^2 - 22x + 15 - 9x^2 + 24x - 16}{(3x-4)(4x-5)} \\ &= \frac{-3x^2 + 6x - 3}{(2x-3)(5x-6)} \div \frac{-x^2 + 2x - 1}{(3x-4)(4x-5)} \\ &= \frac{-3(x-1)^2}{(2x-3)(5x-6)} \times \frac{(3x-4)(4x-5)}{(x-1)^2} \\ &= \frac{3(3x-4)(4x-5)}{(2x-3)(5x-6)} \text{ Ans.} \end{aligned}$$

## EXAMPLES 25

Simplify the following

- $\frac{x^4 - y^4}{x^3 + y^3} \times \frac{x^2 - y^2}{(x-y)^2}$
- $\frac{x^2 + 4x}{x+3} \div \frac{x^2 + 3x}{x+4}$
- $\frac{(x-y)^2 - z^2}{(x-z)^2 - y^2} \times \frac{y^2 - (z-x)^2}{z^2 - (x-y)^2}$
- $\frac{(x^2 - y^2)^2}{(x-y)^4} \times \frac{(x+y)^2}{x^3 - y^3} \div \frac{(x+y)^3}{x^2 + y^2}$
- $\left( \frac{x+a}{x-a} + \frac{a}{x-a} \right) \div \frac{x^2 + a^2}{x^2 + ax}$
- $\frac{x - xy}{x^2 + y^2} \div \left( \frac{x}{x+y} - \frac{y}{x+y} \right) \div \frac{x^2 - y^2}{x^2 + xy} \div \left( 1 - \frac{x^2 - y^2}{x^2 + y^2} \right)$
- $\frac{1}{x-1} - \frac{9}{x-2} + \frac{10}{x-3} \times \left( \frac{1}{x-1} + \frac{2}{x+1} + \frac{5}{1-2x} \right)$

89. Compound Fractions. A fraction, whose numerator or denominator is a fraction, is called a compound fraction. The rules already explained enable us to reduce compound fractions to simple fractions.

Example 1. Simplify

$$\frac{\frac{a+b}{a-b} - \frac{a-b}{a+b}}{\frac{1}{a-b} + \frac{1}{a+b}}$$

Here we notice that the L.C.M. of the denominators of the fractions which form the numerator of the given expression is  $a^2 - b^2$ , and that the L.C.M. of the denominators of the fractions which form the denominator of the given expression is also  $a^2 - b^2$ . Hence, we shall at once have reduced the given expression to a simple fraction if we multiply both numerator and denominator by  $a^2 - b^2$ . We have  $\frac{a+b}{a-b} \times a^2 - b^2$  equal to  $(a+b)^2$  [Art. 83], and so on for each fraction.

Therefore, the given expression

$$\begin{aligned} &= \frac{(a+b)^2 - (a-b)^2}{(a+b) + (a-b)} \\ &= \frac{(a+b+a-b)(a+b-a+b)}{a+b+a-b} \\ &= \frac{2a \cdot 2b}{2a} = \frac{2b \text{ Ans.}}{a} \end{aligned}$$

Example 2. Simplify

$$= \frac{1}{a - \frac{1}{a + \frac{1}{a}}} - \frac{1}{a + \frac{1}{a - \frac{1}{a}}}$$

Fractions of this form are called *continued fractions*. They are simplified as in Arithmetic [Art. 88, page 706] by beginning with the lowest line.

The given expression

$$\begin{aligned} &= \frac{1}{a - \frac{1}{a^2 + 1}} - \frac{1}{a + \frac{1}{a^2 - 1}} \\ &= \frac{1}{a^2 + 1} - \frac{1}{a + \frac{1}{a^2 - 1}} \\ &= \frac{a^2 + 1}{a(a^2 + 1) - a(a^2 - 1)} \\ &= \frac{a^2 + 1}{a^3 - a^2 - a^2 + 1} \\ &= \frac{a^2 + 1}{a^3 - 2a^2 + 1} = \frac{1}{a^3} \text{ Ans.} \end{aligned}$$

### 90. Proper and Improper Fractions.

A proper fraction is one whose numerator is of lower degree than its denominator.

A fraction whose numerator is not of lower degree than its denominator is called an improper fraction. Thus

$$\frac{2x-3}{x^2+5x-9}$$

is a proper fraction; while

$$\frac{2x-3}{4x-1} \text{ and } \frac{2x^2-5x+1}{5x-4}$$

are improper fractions.

An improper fraction can be expressed as the sum of one or more integral terms and a proper fraction, by division. Thus,

$$\begin{aligned} \frac{2x-3}{4x-1} &= \frac{1}{2} \frac{4x-1}{4x-1} - \frac{5}{4x-1} \\ &= \frac{1}{2} - \frac{5}{2(4x-1)}. \end{aligned}$$

## EQUATIONS WITH FRACTIONS

91. An equation containing fractions may be reduced to an equation without fractions by multiplying each side of the equation by the L.C.M. of the denominators of all the fractions which occur.

Example 1. Solve

$$\frac{x-1}{x+3} - \frac{x+2}{x-4} + \frac{10}{x} = 0.$$

The L.C.M. of the denominators is  $x(x+3)(x-4)$ , and, multiplying each side by this expression, we get

$$x(x-4)(x-1) - x(x+3)(x+2) + 10(x+3)(x-4) = 0.$$

Therefore,

$$x^3 - 5x^2 + 4x - x^3 - 5x^2 - 6x + 10x^2 - 10x - 120 = 0$$

Therefore,

$$\begin{aligned} 12x &= -120 \\ x &= -10 \text{ Ans.} \end{aligned}$$

The work is shorter if we reduce improper fractions to proper fractions.

Example 2. Solve

$$\frac{16x-13}{4x-3} + \frac{40x-43}{8x-9} = \frac{32x-30}{8x-7} + \frac{20x-24}{4x-5}.$$

Dividing each fraction by its denominator we get

$$4 - \frac{1}{4x-3} + 5 + \frac{5}{8x-9} = 4 - \frac{1}{8x-7} + 5 + \frac{1}{4x-5}.$$

Therefore,

$$\frac{2}{8x-9} - \frac{1}{4x-3} = \frac{1}{4x-5} - \frac{2}{8x-7}.$$

Therefore,

$$\frac{2(4x-3) - (8x-9)}{(8x-9)(4x-3)} = \frac{(8x-7) - 2(4x-5)}{(4x-5)(8x-7)};$$

or

$$\frac{3}{(8x-9)(4x-3)} = \frac{3}{(4x-5)(8x-7)}.$$

Hence,

$$(8x-9)(4x-3) = (4x-5)(8x-7).$$

Therefore,

$$\begin{aligned} 32x^2 - 60x + 27 &= 32x^2 - 68x + 35 \\ 8x &= 8 \\ x &= 1 \text{ Ans.} \end{aligned}$$

## EXAMPLES 26

Solve the equations

- $\frac{x-6}{4(x-2)} = \frac{x-10}{6(x-2)} + \frac{1}{9}.$
- $\frac{x}{5(x-2)} - \frac{x-2}{5x} = \frac{1}{3x} - \frac{1}{3x(x-2)}.$
- $\frac{7x+1}{x-1} = \frac{35(x+4)}{9(x+2)} + \frac{28}{9}.$
- $\frac{2x-1}{2x+3} - \frac{x}{3x-2} = 1 - \frac{2x(x+3)}{(3x-2)(2x+3)}.$
- $x - a - \frac{ab}{x-b} = \frac{x^2+ab}{x-b}.$
- $\frac{11}{12x+11} + \frac{5}{6x+5} = \frac{7}{4x+7}.$
- $\frac{4(7x-23)}{x+4} - \frac{3x-26}{x+1} = \frac{13(x+5)}{x} + 6.$

Simplify the following expressions

- $\frac{x-a}{1-\frac{1}{b}} \times \frac{a-b}{1-\frac{1}{a}}.$
- $\frac{1}{\frac{a}{b} + \frac{1}{a^2} + \frac{1}{b^2} + \frac{1}{ab}}.$
- $\frac{1+\frac{a}{b}}{b-1} \cdot \frac{x^2-b^2}{2b-b^2}.$

## QUADRATIC EQUATIONS

92. A quadratic equation is an equation which contains the square, but no higher power, of the unknown quantity.

Thus,  $2x^2 = 18$ , and  $5x^2 - x = 6$ , are quadratic equations. The first example, which contains only the second power of  $x$ , is a *pure* quadratic.

To solve a pure quadratic we write the terms which contain  $x$  on one side of the equation, and the remaining terms on the other side. Then, by taking the square root of both sides, we obtain two *simple* equations. Thus, if  $2x^2 = 18$ , we have  $x^2 = 9$ , and, taking the square root of both sides,  $x = +3$ , or  $x = -3$ .

[ $x = 3$ , or  $x = -3$ , is always contracted into  $x = \pm 3$ .]

93. In taking the square root of both sides of the equation  $x^2 = 9$ , it may seem that we should put the double sign to *both* sides of the result, *i.e.*,  $\pm x = \pm 3$ . But this would only give the four following cases,  $+x = +3$ ,  $+x = -3$ ,  $-x = +3$ , and  $-x = -3$ , and it is easily seen that these four cases give no more values of  $x$  than are included in the form  $x = \pm 3$ . Hence, in taking the square root of the two sides it is only necessary to put the double sign before *one* result.

94. In Article 32, page 2150, we found that  $(x+a)^2 = x^2 + 2ax + a^2$ . Now, in the expression  $x^2 + 2ax + a^2$ , the coefficient of  $x$  is  $2a$ , and, if we take the half of this and square it, we obtain  $a^2$ , *i.e.*, we obtain the *third* term of the expression,  $x^2 + 2ax + a^2$ . Hence, *to complete the square of which  $x^2 + 2ax$  are the first two terms we must add the square of half the coefficient of  $x$ .*

Example. To make  $x^2 + 6x$  into a perfect square we must add  $(\frac{6}{2})^2$ , *i.e.*,  $3^2$ , or 9. We then get  $x^2 + 6x + 9$ , which is the square of  $x + 3$ .

It must be particularly noted that *the coefficient of  $x^2$  is unity*. We cannot, for instance, make  $3x^2 + 6x$  into a perfect square by adding the square of half the coefficient of  $x$ .

95. The above result enables us to solve a quadratic which contains both the square and the first power of  $x$ . For, after putting the terms involving  $x^2$  and  $x$  to one side of the equation, and the remaining terms to the other, we can make the first side a perfect square. On taking the square root of both sides, we obtain two simple equations, just as in the case of a pure quadratic.

Example 1. Solve  $x^2 + 4x - 32 = 0$ .

Transposing the term  $-32$ , we have

$$x^2 + 4x = 32.$$

Since the coefficient of  $x^2$  is 1, the left-hand side of the equation becomes a perfect square if we add the square of half the coefficient of  $x$ . The square of half 4 is  $2^2$ . We therefore add this amount to *both* sides of the equation, and obtain

$$x^2 + 4x + 2^2 = 32 + 4;$$

or,

$$(x + 2)^2 = 36.$$

Taking the square root we have

$$x + 2 = \pm 6.$$

Therefore,

$$\begin{aligned} x + 2 &= 6 \text{ or } -6 - 2 \\ &= 4 \text{ or } -8. \end{aligned}$$

Example 2. Solve  $x - 5x^2 = -6$ .

Here, the coefficient of  $x^2$  is  $-5$ . We must,

3200

therefore, first divide every term by  $-5$  in order to make  $x^2$  have unity for its coefficient. Thus

$$x^2 - \frac{1}{5}x = +\frac{6}{5}.$$

We now proceed as in Example 1. The half of  $-\frac{1}{5}$  is  $-\frac{1}{10}$ , and its square is  $(\frac{1}{10})^2$ .

Therefore,

$$\begin{aligned} x^2 - \frac{1}{5}x + \frac{1}{10^2} &= \frac{6}{5} + \frac{1}{100} \\ &= \frac{120 + 1}{100} \\ &= \frac{121}{100}. \end{aligned}$$

Taking the square root,

$$x - \frac{1}{10} = \pm \frac{11}{10}.$$

Therefore

$$\begin{aligned} x &= \pm \frac{11}{10} + \frac{1}{10} \\ &= \frac{12}{10} \text{ or } -\frac{10}{10} \\ &= \frac{6}{5} \text{ or } -1. \end{aligned}$$

96. Instead of working every example from the beginning we may use a general formula.

It is clear that, after simplification, a quadratic may contain three terms, *viz.*, a term involving the second power of  $x$ , a term involving the first power, and a term without  $x$ . Thus, if  $a$ ,  $b$ , and  $c$  are supposed to represent *known* quantities, we may take

$$ax^2 + bx + c = 0$$

as a general quadratic equation.

Solving this, by the method of the last article, we must first divide every term by  $a$ . Thus,

$$x^2 + \frac{b}{a}x + \frac{c}{a} = 0;$$

or,

$$x^2 + \frac{b}{a}x = -\frac{c}{a}.$$

Next, add the square of half  $\frac{b}{a}$  to both sides,

*i.e.*, add  $(\frac{b}{2a})^2$ .

Therefore,

$$\begin{aligned} x^2 + \frac{b}{a}x + \left(\frac{b}{2a}\right)^2 &= -\frac{c}{a} + \frac{b^2}{4a^2} \\ &= \frac{b^2 - 4ac}{4a^2}. \end{aligned}$$

Taking the square root of both sides, we get

$$\begin{aligned} x + \frac{b}{2a} &= \pm \sqrt{\frac{b^2 - 4ac}{4a^2}} \\ &= \pm \frac{\sqrt{b^2 - 4ac}}{2a}. \end{aligned}$$

Therefore,

$$\begin{aligned} x &= -\frac{b}{2a} \pm \frac{\sqrt{b^2 - 4ac}}{2a} \\ &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}. \end{aligned}$$

This result should be committed to memory, since, by its use, the solution of a quadratic equation can at once be written down.

For instance, in Example 2 of the last article,  
 $x - 5x^2 = -6$ ;

or

$$-5x^2 + x + 6 = 0$$

we have

$$a = -5, b = 1, \text{ and } c = 6.$$

Hence,

$$\begin{aligned} x &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \\ &= \frac{-1 \pm \sqrt{1 + 120}}{-10} \\ &= \frac{-1 \pm 11}{-10} = \frac{10}{-10} \text{ or } \frac{-12}{-10} \\ &= -1 \text{ or } \frac{6}{5}. \end{aligned}$$

**97. Solution by Factors.** The product  $ab$  is evidently zero if either  $a$  or  $b$  is zero. Hence, if we know that  $ab$  is zero, we know that either  $a = 0$ , or  $b = 0$ .

Similarly, if  $(x - 1)(x + 2) = 0$ , we know that either  $x - 1 = 0$  or  $x + 2 = 0$ , and therefore  $x = 1$  or  $x = -2$ . Thus, the solution of the equation  $(x - 1)(x + 2) = 0$  is  $x = 1$  or  $-2$ .

In the same way the solution of the equation  $(x + 2)(x + 3)(x + 4) = 0$  is  $x = -2$  or  $-3$ , or  $-4$ .

Hence, to solve any equation involving only one unknown quantity, transpose all the terms to one side of the equation, resolve the expression into factors, and put each factor separately equal to zero. The values obtained from these equations will be the roots of the given equation.

Example. Solve  $x - 5x^2 = -6$ .

Transposing

$$5x^2 - x - 6 = 0.$$

Therefore,

$$(5x - 6)(x + 1) = 0.$$

Therefore,

$$5x - 6 = 0,$$

which gives

$$x = \frac{6}{5};$$

or

$$x + 1 = 0,$$

which gives

$$x = -1.$$

## EXAMPLES 27

Solve, without substituting in the formula of Article 96,

1.  $x^2 - 7x = 10.$
2.  $2x^2 + x - 3 = 0.$
3.  $(x + 4)^2 = 16x + 1.$
4.  $x^2 - 15 = 5 - 8x.$
5.  $9(2x + 1)^2 = (x - 2)^2.$
6.  $x^2 + 6x^2 = 5ax.$

Solve, by the formula of Article 96,

7.  $6x^2 - 13x - 6.$
8.  $(x + 3)^2 = 9(x - 1)^2.$
9.  $132x^2 - 13x = 2.$
10.  $2x^2 + x - 6 = 0.$
11.  $8x^2 + 17 = 70x.$
12.  $20 = 3x + 2x^2.$

Solve, by resolving into factors,

13.  $x^2 - 2ax + a^2 - b^2 = 0.$
14.  $x^3 - 5x^2 - 8x + 12 = 0.$
15.  $x^4 - 13x^2 + 36 = 0.$
16.  $2x^3 - 4 = 8x + x^2.$

## Answers to Algebra

### EXAMPLES 23

1.  $\frac{4c}{9a^2b}.$
2.  $\frac{2a^4x}{5b^2y}.$
3.  $\frac{a}{b}.$
4.  $\frac{x - 1}{x}.$
5.  $\frac{(x - 2)(x + 3)}{x^2 - 1}.$
6.  $\frac{x - 3}{x + 5}.$
7.  $\frac{x - 7}{x - 6}.$
8.  $\frac{1 + a^2}{2 + a^2}.$
9.  $\frac{3x(a + 3)}{2b(a + 1)}.$
10.  $\frac{4x + 3}{3x^2 - 5x + 7}.$  [H.C.F. =  $2x^3 - 4x - 1.$ ]

### EXAMPLES 24

1.  $-\frac{4xy}{x^2 - y^2}.$
2.  $\frac{14x}{1 - 9x^2}.$
3.  $\frac{4x + 1}{(x + 1)^3}.$
4.  $\frac{x^2 + y^2}{x^2 - y^2}.$
5. 3.
6.  $\frac{3}{9 - a^2}.$
7.  $\frac{6 + 2x^4}{1 - x^8}.$
8.  $\frac{6x(x^2 - 2y^2)}{x^4 - 5x^2y^2 + 4y^4}.$
9.  $\frac{1}{a - 2}.$
10. 0.

12. By reducing each fraction to its lowest terms we get

$$\frac{x}{x + y + z} + \frac{y}{x + y + z} + \frac{z}{x + y + z} = \frac{x + y + z}{x + y + z} = 1.$$

THE WHEAT HARVEST IN NORTH-WEST CANADA

Underwood & Underwood  
Twenty-four horses are dragging a machine that cuts the grain, threshes it, packs it into sacks, and ties the straw into bundles. Such a machine can produce 2,500 sacks of grain in one day.

# FARMING IN CANADA

The Golden West. Farming, Stock-raising, and Fruit-growing in the Various Provinces of Canada. Government Experimental Stations

Group 1  
AGRICULTURE

22

FARMING

continued from page 3003

By Professor JAMES LONG

IT is impossible for an Englishman experienced in agriculture to visit Canada without being impressed with the remarkable results which are being achieved year by year. In no country in the world does the Government provide greater assistance for the promotion of agricultural prosperity. For years past efforts have been made not only to ascertain why the crops over large areas of land have been lamentably small where owing to the character of the soil they should be large, but the farmers have been shown by demonstration at the various experiment stations how to increase the grain produced and the income derived from the production of plant and animal life.

**Some General Statistics.** The population of Canada reaches nearly 6,000,000, while its area covers nearly 3,750,000 sq. miles. In 1901, the value of the exported produce reached nearly 44 millions sterling, while 45 per cent. of the population are engaged in the cultivation of the soil, and an additional 20 per cent. are either directly or indirectly employed in handling farm produce or in the manufacture of farm implements and machinery. The great bulk of these exports are directly derived from agricultural land, and the products of the timber industry.

In 1904, the Ontario oat crop alone produced 102 million bushels, or 38½ bushels to the acre. The barley crop is increasing both in area and yield; for some years it was practically restricted to 20 million bushels, of which one-half was exported; but owing to the McKinley Tariff, the area was soon reduced, and the crop grown was not more than one-half. At this time, the farmers of the province, under the advice of Government experts, opened up a larger market with Great Britain, producing quantities of cheese, butter, meat, and eggs, with the result that barley was grown on a larger scale than before to feed the stock, and thus, by more intensive farming, the average yield was brought up to 31½ bushels, instead of 21 bushels, to the acre.

**The Agricultural Provinces.** For the purpose of these remarks, Canada may be divided into the following provinces, agriculturally speaking:

| Province.                | Area.      | Population. | Snow and Rainfall. |
|--------------------------|------------|-------------|--------------------|
|                          | Sq. miles. |             | Inches.            |
| Nova Scotia ..           | 20,680     | 480,000     | 40 to 45           |
| Prince Edw. Island       | 2,000      | 104,000     | 35 to 40           |
| New Brunswick..          | 28,000     | 331,000     | 44                 |
| Quebec ..                | 347,000    | 1,649,000   |                    |
| Ontario ..               | 223,000    | 218,300     | 30 to 40           |
| Manitoba ..              | 73,000     | 255,000     | 17½                |
| Saskatchewan and Alberta | 550,000    | 500,000     |                    |
| British Columbia         | 382,000    | 177,000     |                    |

Although it was only in 1905 that the two new provinces, Saskatchewan and Alberta, were added to the Confederation, the advance which has been made in the North-West and British Columbia may be better estimated if we point out that, while in 1900 the immigrants numbered 49,000, of whom 11,000 were British and 18,000 Americans, the estimated number in 1904 was 180,000. The immigrants from Great Britain in the year ending June, 1905, numbered 65,000, while those from the States had been increased to 43,000. They are practically presented with 160 acres free, and, with a very trifling capital, and the common-sense to learn the ways of the country before they settle, they are ultimately able to achieve happiness and prosperity.

**The Wonderland of the World.** Canada is one of the few countries of the world which possess huge areas of rich land capable of growing grain and other crops without manure for a long series of years. As we shall see, there are many districts in which, in spite of the general severity of the winter, crop growing and stock raising can be conducted through a large portion of the year.

Dairying and fruit growing are becoming general in almost all parts of the country, while on the Pacific Coast and in various districts of British Columbia, the settler possesses great advantages for the pasturage of cattle. According to Dr. Saunders, the chief of the experimental stations, and one of the ablest and safest of advisers, the main elevation of Canada is 300 ft. above sea-level, as compared with 671 ft. in Europe; while the diversity of soil, of plant, of mountain, valley, and lake, rolling prairie and forest land, is easily recognised by the traveller from Halifax to the Pacific Coast, a distance of more than 3,500 miles.

**Value of Experiment.** The Dominion offers great advantages through its five experimental farms, its agricultural colleges and schools—the chief of which is at Guelph, in Ontario—its dairy schools, travelling dairies, farmers' institutes and associations. The Government have established cold storage to assist in the export of perishable goods, and expended large sums in experiment and demonstration, not only at the great Central Farm at Ottawa, but those in Nova Scotia, Manitoba, Assiniboia, and British Columbia. Plants from all parts of the world have been grown with the object of testing their value to the Canadian farmer, while cross-breeding is practised for the same purpose, and the feeding of livestock for the production of meat and milk is conducted on experimental lines. Thousands of samples of seed of important varieties are sent out from Ottawa year by

## AGRICULTURE

year without charge, with the result that the farmers, having tested and found the increased value of certain varieties, are induced to employ them extensively, and to profit by the results. To give an example, it may be pointed out that as the result of experiment wheat sown at intervals of a week showed that a delay of one week after the time when it ought to be in the ground involved an average loss of 30 per cent. of the crop, while a delay of two weeks involved a loss of 40 per cent., three weeks of 50 per cent., and four weeks of 56 per cent.; and so it is with oats, barley, and mangels.

### Advantages and Disadvantages.

Thus it is that the climate plays such an important part in the farmer's work; he has, however, the soil to help him, for it is rich in almost all the agricultural districts of the Dominion. Taking the averages resulting from the work at the Central Farm, it has been found that in the top foot there are 7,700 lb. of nitrogen per acre. Assuming this to be all available, it is sufficient to produce 150 very large crops of grain. Taking the average at the same depth, there are 5,400 lb. of phosphoric acid, enough for 250 large crops, and 11,700 lb. of potash, sufficient for 300 crops. It follows, therefore, that by good cultivation and by sufficient care in the employment of manure, the farmer who takes up land in Canada may look for heavy crops with but little trouble to himself, and leave behind him a heritage which will serve his successors for generations. The Commissioner of Agriculture points out the following difficulties that confront the farmer:

1. Those that arise out of the growing of crops. (These are becoming greater every year from the partial exhaustion of the soil, from the increasing prevalence of weeds, and from the more vicious and general attacks of insects and fungus pests.)

2. Those that come from the necessity of meeting the demands of markets for better qualities in everything.

3. Those which grow out of the changed conditions of life, and which require the farmers to carry on more varied, mixed, or diversified classes of farming. (These come from the growth of population in cities and towns; from the people becoming better off and more fastidious and exacting in their tastes; and through cold storage giving them an opportunity to market perishable things abroad.)

4. Those which have come with low prices for general farm products, and which are beyond the control of the people of this country.

5. Those that are inseparable from maintaining the fertility of soil economically.

All these difficulties are more or less easily overcome where the principles of agriculture have been mastered.

### Nova Scotia

A large portion of this province is covered with timber; although it contains 20,000 square miles, the population of nearly 500,000 is largely engaged in agriculture and stock breeding cultivating the fertile soils between

the ranges of hills with considerable success. The hay crops are large, and form the chief article of produce; the soil is occasionally broken up, however, and sown with oats; wheat, barley, rye, peas, and buckwheat are also grown, together with turnips and potatoes.

The rainfall varies from 40 to 45 in., while the climate, although variable, sometimes in the extreme, is temperate in relation to the latitude.

The production of livestock, chiefly cattle, sheep, and pigs, is considerable, but there is immense scope for an increase in this direction, and the consequent production of much larger quantities of manure, which would contribute to the increase of the crops.

Butter and cheese factories have been established during the past few years with success, while fruit growing is developing still more rapidly, especially in those valleys in which the position, soil, and climate are suitable for the production of the best apples, pears, and stone fruit. Apples in particular enjoy a high reputation. The annual export for some years past has reached 500,000 barrels, but a large increase may be expected, owing to the planting of new orchards, which may be extended in many directions on a large scale.

### Prince Edward's Island

This island is about 150 miles in length, varying from 9 to 30 miles in breadth. It possesses a moist and mild summer climate, while in winter the temperature never falls to a very low figure.

The crops produced by the farmers, who form some 80 per cent. of the population, include wheat, barley, oats, and buckwheat, hay, potatoes, and turnips, the chief products being hay, oats, potatoes, and turnips.

The crops are not so largely exported as formerly, owing to the advance which has been made in the dairy industry, which is conducted on the co-operative principle. Cheese, in consequence, now forms one of the largest items of the export trade, although butter is being made on an extensive scale during winter. Naturally, owing to the by-products of the butter and cheese dairies, the breeding and feeding of swine has extended.

The farmers raise cattle for beef in excess of their requirements; sheep are largely bred, and horses form an important feature on many farms. The result of this extension is that the crops formerly exported are now consumed, with the result that, while the profits are larger, the land is maintained in better condition. Although fruit-growing does not give the results achieved in some other parts of Canada, the industry is growing, and apples, plums, cherries, and small fruits are easily and abundantly produced.

### New Brunswick

Practically one-half of this province is covered with forest and woodland, but although timber has, in the past, formed the most prominent industry, the work of the farmer is destined to obtain the chief place, owing, in part, to the fertile character of the soil and to the good crops which are obtainable where it is well

cultivated. The hay crop is the chief product of the farm, about one-half of the cultivated area, some 1,000,000 acres, being under grass for mowing; the remaining 500,000 acres are chiefly devoted to oats and buckwheat, followed by potatoes, wheat, and barley.

Although the rainfall is sufficiently abundant for crop-producing purposes, the climate is severe in winter, while the summer season is not so hot as in many other parts of the Dominion; indeed, the extremes are not so great.

Stock-rearing on a successful scale is practised, while of late years increasing attention has been devoted to the dairy industry, with the result that there are a considerable number of successful butter and cheese factories.

Owing to the climate, fruit growing has progressed but slowly, but in many cases the industry has found a home, and is, in consequence, steadily progressing, the apple in particular enjoying a good reputation, while small fruits are grown with ease and profit.

### Quebec

Like so many other parts of the Dominion, Quebec produces a large quantity of timber, more than half the province consisting of forest and woodland; there are, however, many fertile valleys in which agriculture is conducted by a large proportion of the population with considerable success. In spite of the varied character of the climate in different districts, the crops grow rapidly during the heat of summer, especially hay, which is one of the chief products, and which is largely exported. The extension of the dairy industry, however, is tending to the increase of stock breeding and the larger consumption of the hay crop, as well as of the coarser grain, which is more profitable for milk, butter, and cheese production than for sale.

The chief grain crops are oats and wheat, but barley, rye, maize, peas, buckwheat, potatoes, mangels, turnips and sugar-beets, tobacco and flax are also successfully grown. Much of the soil is extremely fertile, so that, while heavy crops can be produced by good farming, stock can be kept, and be well fed during the cold but bracing winters, when the attention of the farmer is almost entirely concentrated upon it.

In some parts of Quebec the farmers are most successful in breeding horses, while in suitable localities apples, pears, plums, and other fruits are grown with great success, although in other parts the winters are too severe for the ripening of the best varieties.

### Ontario

The area of Canada's chief province, Ontario, is 141,000,000 acres, of which, in 1903, 13,643,000 acres were cleared, 6,700,000 consisting of woodland, and 3,500,000 of swamp or marsh. The area devoted to the leading crops and the quantities estimated to have been produced in 1904 are shown in next column.

In addition to the crops shown, 6,000 acres were devoted to carrots, 49,000 acres to rape, 2,250 acres to hops, 6,300 acres to flax, 3,000 acres to tobacco, and 14,000 acres to the culti-

|   | 369,459   |             |

vation of the vine. The number of livestock in Ontario in 1904 was as follows:

|                 |           |                             |           |
|-----------------|-----------|-----------------------------|-----------|
| Milk Cows ..    | 1,078,000 | Pigs .. ..                  | 1,927,000 |
| Other cattle .. | 1,697,000 | Horses .. ..                | 655,000   |
| Sheep .. ..     | 1,455,000 | Turkeys, Geese, and Poultry | 9,400,000 |

There are in Ontario no less than 100,000 acres of forest and woodland, the timber trees including oak, ash, elm, the white and red pines, hickory, and walnut.

The districts suitable for agricultural purposes are numerous and extensive, while of the 12,000,000 acres of land which have been cleared no less than 11,000,000 acres are under grass and arable crops. Much of the soil is of excellent quality and highly fertile, while in the southwest of the province the climate is mild. In the districts near the Great Lakes the winters are not very severe, nor the summer season too oppressive.

In addition to the crops which have been enumerated, the farmers of the province produced, in a recent year, to take an average example, clover and alsike seed which covered 189,000 acres.

**Fruit Growing.** The fruit growing capacity of Ontario is well known, chiefly owing to the large consignments which we receive in this country. The possibilities of production are believed to be unlimited; already the area occupied by orchards and vineyards exceeds 360,000 acres. The planted apple trees number considerably more than 11,000,000, while the apple crop in a recent year reached 37,000,000 bushels, or 5½ bushels per tree of bearing age. In a good year, this crop is much exceeded; in 1896, for example, with a much smaller area, the yield was 56,000,000 bushels. Dr. Saunders points out that in one part of Ontario alone the apple country extends to a distance of 288 miles. Grapes, too, are produced in abundance, a large portion of the crop being employed in the production of a native wine. The growth of pears, stone, and small fruits is large, and increasing in all parts of Ontario, while in addition to the export of raw apples, large quantities are dried by evaporation for the general market.

### Manitoba

Manitoba is west of and adjoining Ontario, while its position is about central, as between the Atlantic and the Pacific. It chiefly consists of rolling prairies with occasional valleys and rivers, the soil being to an extraordinary extent of a deep, rich, vegetable character, highly fertile, and capable of bearing crops for many years in succession. The proportion of forest and woodland is estimated to reach 40 per cent., but in the chief agricultural districts very little timber is noticeable. The climate is somewhat extreme—warm in summer; cold and invigorating, owing to the dryness of the air, in winter, which commences in November and continues until the end of March or a little later. The precipitation is small, and chiefly deposited between April and October. Although the land available for farm purposes reaches 30,000,000 acres, the area under crop scarcely reaches one-eighth. The farmers commence to sow their seed in April, while they harvest their crops in the month of August, wheat being the most important. The No. 1 hard wheat of Manitoba, like that of the Territories adjoining in the north-west, is unexcelled, and when comparisons were made with the products of other countries exporting to England, the quotations in Liverpool were 4s. 7d. per bushel for No. 1, 4s. 6½d. for No. 2., 4s. 2d. for the best Russian wheat, 4s. 1d. for Argentine, and 3s. 9d. for Indian. In Manitoba the oat crop reached 38½ bushels in a recent year, but, as in Ontario and elsewhere, the higher yield is chiefly owing to the special use of the Banner variety, which at almost all the experimental stations produced more bushels per acre than any other variety under test. The result of this form of success has been that the oat crop in 1904 was four times as large as in 1900.

**Long Hours of Work.** Certain friends of the writer, who are engaged in mixed farming in the Province, some years ago abandoned the practice of wheat growing alone, and have since produced milk and pork for the butter and bacon factories with great success, feeding their stock upon their own produce, which, having sown the seed, they reap themselves at little expense, undergoing an amount of labour in the pursuit of their industry which is practically unknown to workmen on the British farm. Canadian farming provides an incentive to work long hours, and to rely upon one's own efforts, which has possibly never been contemplated by the English farmer or the labourer whom he employs. The climate of Manitoba is too severe for the production of the best kinds of fruit. The growth of garden produce of other kinds, however, is easy; the potato, pulse, plants of the cabbage tribe, rhubarb, maize, tomatoes, and small fruits are all grown with success, although tomatoes require the aid of glass. In Manitoba the estimated quantities of grain produced in 1904, including rye, peas, and maize, were 86,750,000 bushels, these crops being grown upon 3,730,000 acres, in addition to which 3,800,000 bushels of potatoes were grown upon 24,000 acres, 464,000 bushels of flax on 35,000 acres, and

3,750,000 bushels of roots on 14,000 acres. In the same year Manitoba possessed 143,000 horses, 306,000 head of cattle, 18,000 sheep and 118,000 pigs. The total area is 41,169,000 acres.

### Saskatchewan and Alberta

In the north-west territories, which include Assiniboia and Alberta, the crops and produce in 1904 were as follows:

| Crops.               | Acres.    | Bushels.   |
|----------------------|-----------|------------|
| Wheat (Spring) .. .. | 957,253   | 16,723,412 |
| Wheat (Fall) .. ..   | 8,296     | 152,125    |
| Barley .. ..         | 86,154    | 2,205,434  |
| Oats .. ..           | 523,634   | 16,335,519 |
|                      | 1,575,337 | 35,416,400 |

In addition, 16,000 acres were devoted to flax, which produced 170,000 bushels. The number of livestock in these Provinces in 1901 consisted of 591,000 cattle, 176,000 horses, 154,000 sheep, and 73,000 head of swine. The comparatively low average of production in Manitoba and elsewhere in oats, wheat, and potatoes is chiefly the result of bad workmanship on the part of a number of farmers, who do not act upon the lessons which the Government are teaching them. The best farmers, however, like the directors of the Government farms themselves, are able to grow an average of 50 to 60 bushels of oats and from 300 to 400 bushels of potatoes. In experimental fields, however, as many as 500 bushels have been grown, while the oat crops have reached 115 bushels to the acre. The success of the oat crops on the soils of Manitoba is remarkable where cultivation is clean and practical, especially in view of the fact that larger yields are obtained by the employment of 2 to 2½ bushels of seed, instead of 4 to 5 bushels, as is common in this country.

### British Columbia

This province is clothed with high mountains and fertile valleys exhibiting considerable climatic variations and great productive powers. In those districts suitable for agriculture, stock raising, and fruit growing, the climate between the mountain ranges and the coast is mild and closely resembles that of many parts of the British Isles. In some parts of the province the rainfall is deficient, with the result that irrigation is necessary, but the soil is rich and well adapted to productive purposes in many valleys. The further we get from the sea, the more severe the climate—the greater the warmth in summer and the cold in winter. According to Dr. Saunders, the rainfall reaches 67 in. at the experimental farm of Agassiz, which is about 70 miles east of Vancouver. The chief crops are hay and oats, followed by potatoes, roots, barley, and wheat, while hops and flax are also grown with success. Stock rearing is not extensive, but good dairy herds are becoming more general, and butter-factories are prosperous. There is an immense area of land adapted to the cultivation of apples, pears, plums, and cherries, while smaller bush fruits and strawberries are easily grown.

**Relative Pronouns.** These are as follow:

QUE, who, which, that. QUIEN, who.  
CUAL (used with definite article), who, which.  
CUYO, whose, of which, which.

1. QUE is invariable in gender and number, it relates to persons in the nominative and accusative only, and to things in all cases.

Examples: *El hombre que cantó*, The man who sang. *Las cosas de que hablamos*, The things of which we speak.

QUIEN, plural QUIENES, relates to persons only, and is invariable in gender. The accusative whom is rendered by *a quien* or *que*. Examples:

*El hombre a quien mataron*, *El hombre que mataron*, The man whom they killed.

*Los hombres a quienes mataron*, The men whom they killed.

NOTE. The relative pronoun is never omitted in Spanish in such cases. "The men they killed" would be incorrect.

2. CUAL, plural CUALES, is invariable in gender. It relates to persons and things, and is generally accompanied by the definite article agreeing with the antecedent. It is substituted for *quien* and *que*. Examples: *Han escrito una carta la cual recibí*, They have written a letter which I have received. *Tenemos un amigo, el cual vive en la casa de enfrente*, We have a friend, who lives in the house opposite.

*Cual* is used without the article to express comparison; in such cases it is often preceded by *tal*, and may be translated, *as, like, such as*.

Examples: *Una mujer cual se puede admirar*, A woman such as one can admire. *Hay que sufrir la pena tal cual viene*, Suffering must be endured, such as it comes. *Cual un angel de Dios*, Like an angel of God.

*Cual* is also used without the article in sentences of interrogation or doubt. Examples:

*¿No sé cual de los libros es mío*, I do not know which of the books is mine. *¿Cuál de los dos prefiere Vd?* Which of the two do you like best?

*Lo cual* is the neuter form and has a phrase or sentence for its antecedent. Example: *Le dijo algo, lo cual no escuché*, He said something to me to which I did not listen.

*Que* is also used with a definite article in the same way as *cual*; *el que*, he who, *la que*, she who, *los que*, they who, those which, etc. Examples: *Este hombre es el que nos habló ayer*, This man is he who spoke to us yesterday. *Estas sillas son las que necesitamos*, These chairs are those which we want.

3. CUYO, fem. CUYA, whose, of which, which relates to persons or things and agrees in gender and number with the object possessed. Examples: *La muchacha cuya belleza se admira*, The girl whose beauty is admired. *Los reos cuyos crímenes se han de castigar*, The criminals whose crimes must be punished.

All these relative pronouns take an accent when used interrogatively. Examples:

*¿Qué dice?* What does he say? *¿Quién es?* Who is it? *¿Cuáles de los libros quiere Vd?* Which of the books do you want?

The use of *cuyo*, whose, as an interrogative is inelegant; it should be rendered by *de quien*, of whom. Examples: *¿De quién son esas casas?* Whose houses are those?

**Indefinite Pronouns.** The indefinite pronouns are as follow:

ALGUIEN, somebody, someone, anybody, anyone; invariable, relating to persons only.

ALGUNO, somebody, etc., some; variable in gender and number, relating to persons and things.

ALGO, something; invariable.

NADIE, nobody, no one; invariable.

NADA, nothing; invariable.

NINGUNO, nobody, no one, none; relating to persons and things, variable in gender and number.

QUIENQUIERA, whoever, anyone, whatever; relating to persons only; invariable.

CUALQUIERA, plural CUALESQUIERA, whoever, anyone, whatever; relating to persons and things; invariable in gender.

TODO, all; variable in gender and number, relating to persons and things.

OTRO, other, another, variable in gender and relating to persons and things; it can never be used with the indefinite article.

## Vocabulary

### EXERCISE IX. (1).

Translate the following into Spanish:

1. That woman came like an angel of God. . . . vino
2. Who sang? No one sang. 3. Someone came this morning. 4. Someone has told me. . . . mañana
5. There is something to say. 6. He told me nothing. 7. No one knows the criminal. 8. Whoever said this is a liar. 9. He is a nobody; . . . cualquiera anybody can see it. 10. All speak English.
11. Another admiral and another frigate. . . .
12. That man is uncouth, but that other is courteous. 13. That man was condemned to death.
14. They do not trust that woman, she is of little . . . se fían worth. 15. That collegian is studious. 16. That man is a medical student, and will be a good doctor. 17. The criminal was hanged . . . fué this morning.

### EXERCISE IX. (2).

Translate the following into English:

1. ¿Quién ha escrito la carta? 2. ¿Qué desgracia!
3. ¿A quién debe Vd dinero? 4. Los hombres á . . . owe . . . quienes mataron lo merecían. 5. ¿Cómo lo gusta á Vd esa mujer? Vale poco. 6. Tal cual fué su mala vida, tal fué su muerte. 7. El criminal fué ahorcado. 8. El albañil y el enjalbegador han llegado. 9. El falsario era un mentiroso. 10. El arquitecto estaba borracho. 11. El armero tiene mi fusil.

### PROSE EXTRACT VII.

From "Diario de un Testigo de la Guerra de Africa" ("Diary of an Eye-Witness of the War in South Africa"). By Pedro Antonio de Alarcón.

#### THE EFFECTS OF MILITARY SERVICE.

The peaceful habits and customs of the city, the necessities of a pampered existence are fading from our memories and dying out of our minds, giving place to other customs, other habits, other necessities and other interests.

#### LOS EFECTOS DEL SERVICIO MILITAR.

Las costumbres pacíficas los hábitos de la ciudad, las necesidades de una existencia regada van desvaneciéndose en nuestra memoria y amortiguándose en nuestra mente, cediendo su puesto á otras costumbres, á otras hábitos, á otras necesidades y preocupaciones.

War becomes incarnate in us, identifies itself with our being, and constitutes our character. For myself it seems to me that I was born in it, and I find its hardships and discomforts quite natural. Morning and evening would now seem strange to me without the sound of Reveille and Retreat. The tent is a matchless dwelling, the bed no longer seems hard to me, the food could not be more appetising. To go to bed at ten is to be up all night; he who does not see the sunrise is no early riser. To sleep without undressing has its advantages.

When we hear that a friend of ours has been

La guerra encarna en nosotros, se identifica con nuestro ser, constituye nuestro carácter. Yo mismo creo haber nacido en ella, y encuentro muy naturales sus molestias é inconvenientes. Ya no comprendería un amanecer sin toque de divina, ni un anochecer sin toque de retreta. La tienda es una casa inmejorable; el lecho ha dejado de parecerme duro; la comida no puede ser mas apetitosa. Acostarse á las diez es trasnochar; el que no ve salir el sol, no madruga. No desnudarse para dormir tiene sus ventajas.

Cuando se nos dice que un amigo nuestro

wounded, it has the same effect upon us as it would have had formerly to hear that he had lost at cards. "Is it much?" we ask, and think no more about him.

To die is equivalent to going on a journey. *So-and-so is dead*, is the same as to say, *So-and-so has left Africa*. *What! I am very sorry . . . he was a good fellow*. *We shall get along without him*. This is the kind of sorrow caused by such news, the funeral panegyric and oration which accompanies those who die.

Going into action is like going to the bullfight; to assemble in a tent and talk is a pleasure as sweet as ball or opera; to come upon the corpse of a Moor in a field surprises one no more than if it were a favourite flower; not to sleep in a pool of water is the *ne plus ultra* of comfort.

Thus, we live at the wars as in our element; a thousand futile joys and puerile pleasures occupy our days; our necessities have reduced themselves to the level of our resources for their gratification, and now, as ever, cheerfulness has followed resignation.

Pedro Antonio de Alarcon (1833-1891),

ha sido herido, nos produce el efecto que nos hubiese causado ántes oír decir que habia perdido al juego. "¿Es mucho?" se pregunta, y no se vuelve, á pensar en él.

Morir equivale á viajar. *Fulano ha muerto*, es como si se dijera. *Fulano se ha ido de Africa*. ¡Hombre! lo siento . . . era buen chico . . . *Nos pasaremos sin él*. Hé aquí el género de pena que causa esta noticia; el elogio fúnebre y la oración que acompañan á los que mueren.

Entrar en acción es como ir á los toros; reunirse en una tienda á hablar, un placer tan dulce como un baile ó una ópera; ver en un campo un cadáver moro, le sorprende á uno como si encontrase una flor de su gusto; no dormir en un charco de agua, es el *ne plus ultra* de la comodidad.

Vivimos, pues, en la guerra como en nuestro elemento; mil fútiles goceos y pueriles placeres ocupan nuestros días, nuestras necesidades se han reducido al nivel de los medios de satisfacerlas, y la alegría, ahora como siempre, ha venido en pos de la resignación.

Pedro Antonio de Alarcon (1833-1891),

very popular as a writer of short stories, some of which have been translated into English. Alarcon was also distinguished as a journalist, and acted as war correspondent to "La Iberia" during the war in Morocco in 1859. The above extract is taken from his vivid account of the campaign, written in the form of letters to the paper, and afterwards published in book form.

muy popular como escritor de cuentos, de los cuales algunos han sido traducidos al inglés. Alarcon fué también distinguido como periodista, sirvió como corresponsal en la guerra de Marruecos en 1859, para "La Iberia." El extracto dado mas arriba es tomado de su brillante relación de la campaña, escrita en forma de cartas para este periodico, y despues publicadas en forma de libro.

#### KEY TO EXERCISE VIII. (1).

1. Este gaban es mio, y este vestido es tuyo.
2. Estas flores son mías, estos libros son tuyos.
3. Salvé mi vida con un salvavidas.
4. Tus manos están limpias. Su cara es bonita.
5. Su vida de Vd es trabajosa.
6. Dios guarde á Vuestra Majestad.
7. Amigo mio está nevando, no se puede salir.
8. Querido amigo mio, no temo la nieve.
9. Unos vecinos nuestros han sido matados por un rayo.
10. Aquel niño está enfermo.
11. Un cohete cayó sobre aquella mujer.
12. Esas nubes oscurecen el cielo.
13. Esa es agua del mar.
14. Aquel hombre mató á su hermano—esto es lo que me han dicho; no lo creo.

#### KEY TO EXERCISE VIII. (2)

1. I do not care what they have said.
2. That which they have said is not the truth.
3. That is mine; it is my hat and my book.
4. Those men are good.
5. My dog is in the house with that man.
6. This house, and that church are mine.
7. This is bad, and that is good.

## ITALIAN

Continued from  
page 3200

### Modification of Substantives and Adjectives

The original simple meaning of substantives and adjectives may be altered by the addition of suffixes, which generally convey an idea of diminution (diminutives) or increase (augmentatives)—e.g., *libro*, book; *libretto*, small book; *librone*, large book.

The idea of diminution often implies prettiness, gentleness, etc., but sometimes contempt—e.g., *librettino*, a pretty little book; *liberculo*, a valueless little book. The idea of increase often

implies rudeness and coarseness—e.g., *libraccio*, a large, ugly book; *stanziaccia*, an ugly large room.

**Diminutive Suffixes.** The diminutive suffixes most frequently used are:

1. -INO, -ICINO (*cino*, *ce-chee-no*). Examples: *ragazzo*, boy, *ragazzino*, little boy; *mano*, hand, *manina*, a pretty little hand; *lume*, lamp, *luminino*, a little lamp. Nouns ending in -one take the termination *cino*—e.g., *bastone*, stick, *bastoncino*, an elegant little stick; *botton*, button, *bottoncino*. The termination *ino* is also used to denote a younger member of the family, as:

By Francesco de Feo

*padrone*, master, *padroncino*; *principe*, prince, *principino*.

2. **FILLO, ERELLO, CELLO** (èhllò, ehrehllo, chèllo) are mostly used with substantives—e.g., *fuoco*, fire, *focherello*, a nice little fire; *fatto*, story, *fatterello*, a little story; *fiume*, river, *fiumicello*, a little river; *bastone*, stick, *bastoncello*, a common little stick.

3. **ETTO**. Examples: *casa*, house, *casetta*, a pretty little house; *fischio* (fèeskeeo), whistle, *fischietto*, a little whistle; *semplice*, simple, *semplicetto*, rather simple.

4. **OTTO, ACCIOTTO** (ahckeeòtto). Examples: *giovine*, young, *giovinotto*, a smart young man; *vecchio*, old; *vecchiotto*, a fine old man; *grasso*, fat, *grassotto*, rather fat. These terminations denote also young animals: *aquila* (àhkoo-eelah), eagle, *aquilotto*; *orso*, bear, *orsacchiotto*.

5. **UCCIO, ICCIOLO** (oòcheeo, èchceòlo). Examples: *bocca*, mouth, *bocciuccia*, a little beautiful mouth; *strada*, street, *stradiciola*, a little street; *letto*, bed, *lettuccio*, a small bed.

The termination *uccio* is also used to express commiseration. Examples: *animale*, animal, *animaluccio*, a poor little animal; *ragazzo*, *ragazzuccio*, a poor little boy.

6. **UZZO, OLO, UCCOLO** (oòtso, oòcolo) are often used to express contempt—e.g., *faccenda* (fahchehdnah), affair, *faccendiccia*, a small household affair; *poeta*, poet, *poeticcolo*, poetaster; *medico*, physician, *medicuzzo*, "an ass of a doctor."

**Augmentative Suffixes.** The augmentative suffixes most frequently used are:

1. **ONE**. Examples: *Uomo*, man, *omone*, a big man; *carrozza*, carriage, *carrozzone*, a great ugly carriage; *dottore*, doctor, *dottorone*, a great doctor. Feminine substantives become masculine. Masculine substantives have a feminine in *ona*. Examples: *bestia*, beast, *bestione* (m.); *fanciullo*, child, *fanciullone* (m.), *fanciullona* (f.).

2. **AZZO, -ACCIO, -ASTRO** (àhtso, àhckeeeo, àhstro) imply contempt. Examples: *roba*, goods, *robaccia*, rubbish; *uomo*, man, *omaccio*, an ill-bred man; *donna*, woman, *donnaccia*, virago; *giovine*, young, *giovinaastro*, a dissolute young man; *amore*, love, *amorazzo*, intrigue. The termination *-accio* with adjectives expresses also commiseration: *povero*, poor, *poveruccio*, poor man. The termination *astro* signifies also likeness, but always with a sense of depreciation: *verde*, green, *verdastro*, of an ugly greenish colour; *giallo*, yellow, *giallastro*, of an ugly yellowish colour.

3. **AGLIA** (àhleeah). Examples: *ciurma*, crowd, *ciurmaglia*, rabble; *plebe*, plebeians, *plebaglia*, mob; *gente*, people, *gentaglia*, roughs.

**NOTE.** No absolutely fixed rules exist respecting the formation of the diminutives and augmentatives. Some words form many, some few, some none. The various shades of meaning are to be learned only from use. With the very common ones the student will easily become acquainted; the others he may very well leave until he becomes a little proficient in the language, as it is quite possible to be understood

without employing them, and by using the adjective as in English—for example, instead of saying *libretto*, little book, saying *piccolo libro*.

## CONVERSAZIONE.

Vi piacciono questi fiorellini?

Sì; sono belli, ma i fiori del nostro giardino sono molto più belli.

Dove avete passato l'estate?

In campagna; non mi piace la vita di città.

Avete ragione; la vita di campagna è molto più piacevole.

Com'è questo vino?

Il vino non è così cattivo come l'altro, ma la birra è pessima.

Chi è questa ragazzaina?

È la figlia minore di quel buon vecchietto.

È tanto carina, ma è un po' malatuccia; poverina, ha le manine fredde fredde.

A che ora avete appuntamento con la vostra cuginetta?

Alle otto, dobbiamo aspettare (we must wait) ancora un'oretta.

Tanto meglio, avremo tempo di fumare (to smoke) una sigaretta o di fare una passeggiatina nel parco.

## THE VERB

The Italian verbs end in the infinitive with the syllable *-re*. This syllable is preceded by the vowels *-a*, *-e*, *-i*, which are called *characteristic vowels*. By these three vowels three conjugations of verbs are distinguished.

First conjugation in *-a-re*, as: *parlare* (pahrlàh-reh), to speak.

Second conjugation in *-e-re*, as: *credere* (crèhdèh-reh), to believe.

Third conjugation in *-i-re*, as: *vestire* (veh-stèèh-reh), to dress.

The tenses of the verbs are formed with the following terminations:

*Imperfect of the Indicative*: *-vo*, *-vi*, *-va*, *-vamo*, *-vate*, *-vano*. (Pronounce: *vo*, *vee*, *vah*, *vàh-mo*, *vàh-te*, *valno*.)

*Imperfect of the Subjunctive*: *-ssi*, *-ssi*, *-sse*, *-ssimo*, *-ste*, *-ssero*. (Pronounce: *ssee*, *ssee*, *sseh*, *ssee-mo*, *seh*, *ssehro*.)

*Future of the Indicative*: *-rò*, *-rai*, *-rà*, *-rèmo*, *-rete*, *-ranno*. (Pronounce: *rò*, *ràh-ee*, *ràh*, *rèh-mo*, *rèh-teh*, *ràh-nno*.)

*Present of the Conditional*: *-rèi*, *-rèsti*, *-rèbbe*, *-rèmmo*, *-rèste*, *-rèbbero*. (Pronounce: *rèh-ee*, *rèh-ste*, *rèhbbeh*, *rèhmmo*, *rèh-ste*, *rèhbbehro*.)

The above terminations are the same for the verbs of all three conjugations, and are added to the infinitive without the syllable *-re*. The verbs in *-a-re*, in the future and in the conditional, change the *characteristic vowel a* into *e*. To simplify this we may say that the terminations for the future indicative and the present conditional of the verbs of the first conjugation are:

*Future Indicative*: *-erò*, *-erai*, *-erà*, *-erèmo*, *-erete*, *-eranno*.

*Present Conditional*: *-erèi*, *-erèsti*, *-erèbbe*, *-erèmmo*, *-erèste*, *-erèbbero*.

They are added to the infinitive without the termination *-a-re*.

*Present Indicative.*

For the verbs in *-(are)*: -o, -i, -a, -iàmo, -àte, -ano.

For the verbs in *-(ere)*: -o, -e, -iàmo, -ète, -ono.

For the verbs in *-(ire)*: -o, -i, -e, -iàmo, -ète, -ono.

Pronounce: o, ee, ah, eh, ee-ahmo, àhteh, èhteh, ètèh, ahn.

*Past Definite.*

For the verbs in *-(are)*: -ài, -àsti, -ò, -àmmo, -àste, -àrono.

For the verbs in *-(ere)*: -èi, -èsti, -è, -èmmo, -èste, -èrono.

For the verbs in *-(ire)*: -ii, -isti, -immo, -iste, -irono.

Pronounce: ah-er, àhstee, ò, àhmmo, àhsteh, àhrono; èh-ee, èh-ste, èh, èhmmo, èhsteh, èhrono; èè-ee, cìstee, èè, èèmmo, èèsteh, èèrono.

The verbs in *-ere* may also have the terminations: -itti, -èsti, -ette, -èmmo, -èste, -èltero.

Pronounce: èh-ttee, èhstee, èhtteh, èhmmo, èhsteh, èhtteh-ro.

*Present Imperative.*

For the verbs in *-(are)*: -, -a, -i, -iàmo, -àte, -ino.

\* For the verb in *-(ere)*: -, -i, -a, -iàmo, -ète, -ano.

For the verb in *-(ire)*: -, -i, -a, -iàmo, -ète, -ano.

*Present Subjunctive.*

For the verbs in *-(are)*: -i, -i, -i, -iàmo, -iàte, -ino.

For the verbs *-(ere)* and *-(ire)*: -a, -a, -a, -iàmo, -iàte, -ano.

*Continued*

*Gerund. Present Part. Past Part.*

*-(are)*: -àndo, -ànte, -àto, -a, -i, -e.  
*-(ere)*: -èndo, -ènte, -èto, -a, -i, -e.  
*-(ire)*: -èndo, -ènte, -èto, -a, -i, -e.

The above terminations are added to the infinitive without *-are, -ere, -ire*.

KEY TO EXERCISE XVII.

1. Peter is as good as Charles. 2. I have as much money as you. 3. My father is richer than your friend. 4. That watch is dearer than that chain. 5. The dog is more faithful than the cat. 6. Winter is much colder than autumn, and spring is much less warm than summer. 7. These houses are more high than broad. 8. Yesterday it was cold, but to-day it is much colder. 9. If to-morrow is warmer we will all go and take a walk into the country. 10. This street is too long, the other is much shorter.

KEY TO EXERCISE XVIII.

1. This music is very beautiful. 2. Dante is the greatest poet of Italy. 3. This is the most beautiful page of our history. 4. The greatest debt is a benefit received. 5. The poor are often happier than the rich. 6. If you have spent all your money, so much the worse for you. 7. Steel is harder than iron. 8. We are very much satisfied with our studies. 9. The boys have studied all day. 10. So much the better; the more they study, the more they learn. 11. It is better not to speak of certain things. 12. That girl is very beautiful; she has very black eyes, and hair as fair as gold. 13. My youngest brother is at college, he is a very intelligent boy; he is the best of all the pupils. 14. Do you like my new suit? 15. I do not like it much, it is too light; my suit is much darker. 16. I live very far off, but our friend lives much farther off. 17. Often the remedy is worse than the evil.

# FRENCH

By Louis A. Barbé, B.A.

## USES OF THE TENSES

### Indicative Mood

1. The PRESENT OF THE INDICATIVE is used to express: (a) An action which is taking place at the moment of speaking: *Je vois qu'il pleut*, I see that it is raining. (b) An action that habitually takes place: *Je le vois tous les jours*, I see him every day.

2. In French there is no "periphrastic," or "progressive" form of the present. "I am writing," "we are reading," etc., must be rendered by the simple present, *j'écris*, *nous lisons*.

3. After *si* (if) the present indicative is used both of present and of future action:

*S'il pleut nous ne pouvons pas sortir*, If it is raining we cannot go out.

*S'il part demain je vous le ferai savoir*, If he starts to-morrow I shall let you know.

4. A special use of the French present, instead of the English perfect, is to express an action begun at a past time, and continuing up to the

present. In this construction it requires either *depuis* or *il y a . . . que*. With *depuis* the order of the words is, first the verb, next *depuis*, and finally the expression of time:

*Nous sommes ici depuis trois semaines*, We have been here for (the last) three weeks.

*Je vous attends depuis dix minutes*, I have been waiting for you for (the last) ten minutes.

5. *Il y a* begins the sentence, and is followed by the expression of "time how long," then by *que*, and lastly by the verb:

*Il y a trois semaines que nous sommes ici*, We have been here for three weeks.

*Il y a dix minutes que je vous attends*, I have been waiting for you for ten minutes.

6. With "point of time since when" *depuis* only can be used:

*Nous sommes ici depuis le premier août*, We have been here since the 1st of August.

7. When the expression of "time since when" is identical with an expression indicating the time of day, *il y a* must be used to avoid ambiguity.

*Je vous attends depuis une heure* means "I have been waiting for you for the last hour"; but it also means, "I have been waiting for you since one o'clock." When the former meaning is intended, it is therefore better to say, *Il y a une heure que je vous attends*.

8. The IMPERFECT INDICATIVE is used to express what was taking place when something else took place: *Je lisais quand vous êtes entrés*, I was reading when you came in.

It is also used to express what used to take place: *L'année dernière je le voyais tous les jours*, Last year I used to see him every day.

9. It is the descriptive past tense, and, in a narrative, is used to express attendant circumstances, natural phenomena, manners, customs, etc.

*Les rayons de la lanterne éveillaient les insectes et attiraient les phalènes qui venaient en battre la corne de leurs ailes poussiéreuses. Le temps était noir. Un coin de la lune se devinait à peine à travers les crevasses d'un nuage couleur d'encre.* The rays of the lantern awoke the insects and attracted the moths, which came and beat against its horn with their dusty wings. The weather was black (lowering). A corner of the moon could barely be traced (lit., guessed) through the chinks of an ink-coloured cloud.

10. The imperfect indicative is used after *si* in hypothetical sentences: *S'il était ici, nous le verrions*, If he were here, we should see him.

11. The imperfect indicative is used in French instead of the English pluperfect to express an action, which, having been begun at a past time, was still going on at a time now also past. In this construction *depuis* or *il y a . . . que* must be used just as they are used in the analogous construction with the present tense:

*Il y avait deux ans que durait le siège*, The siege had lasted for two years.

12. The PAST DEFINITE is used to present an action as completely past, and in such a way that the beginning and the end of that action are brought before the mind:

*En mil six cent huit, le Français Samuel de Champlain fonda la colonie du Canada*, In 1608, the Frenchman, Samuel de Champlain, founded the colony of Canada.

13. The duration of an action is expressed by means of the past definite provided it be considered as a single definite point in past time. When this is the case, the verb is usually modified by an adverb or adverbial phrase of time:

*Louis XIV. régna soixante-douze ans*, Louis XIV. reigned seventy-two years.

14. The past definite is the tense of historical narrative, and is used to express a succession of actions of which each is complete in itself:

*Pythéas de Marseille, vers le milieu du quatrième siècle avant Jésus-Christ, fit un voyage dans le nord de l'Europe, longea les côtes de la Gaule, entra dans la Manche, visita les côtes méridionales et orientales de l'île de Bretagne, détermina la latitude de l'extrémité nord de cette île, et après six jours de navigation parvint à*

*Thulé, au delà de laquelle il ne put naviguer, empêché qu'il fut par d'épais brouillards*,

Pytheas of Marseilles, about the middle of the fourth century B.C., made a voyage in the north of Europe, skirted the coasts of Gaul, entered the Channel, visited the southern and eastern coasts of the island of Britain, ascertained the northern latitude of that island, and after six days' sailing, reached Thule, beyond which he could not sail, being prevented by dense fogs.

In the following passage, the change from past to imperfect illustrates the difference between the narrative and the descriptive tense, between that which expresses transition from one state to another, and is used for successive actions, and that which expresses state or condition at a certain moment, and is used for simultaneous actions:

*La lune se leva derrière la redoute de Cheverino. . . Elle était large et rouge comme cela est ordinaire à son lever. Mais ce soir-là elle me parut d'une grandeur extraordinaire. Pendant un instant la redoute se détacha en noir sur le disque éclatant de la lune. Elle ressemblait au cône d'un volcan au moment de l'éruption. Un vieux soldat, auprès duquel je me trouvais, remarqua la couleur de la lune. "Elle est bien rouge," dit-il . . . Cet augure m'affecta. Je me couchai, mais je ne pus dormir. Je me levai, et je marchai quelque temps, regardant l'immense ligne de feux qui couvrait les hauteurs au delà du village de Cheverino*,

The moon rose behind the Cheverino redoubt. It was broad and red, as is usual at its rising. But that evening it seemed to me of extraordinary size. For a moment the redoubt stood out in black on the bright disc of the moon. It resembled the cone of a volcano at the time of an eruption. An old soldier near whom I happened to be, noticed the colour of the moon. "It is very red," he said. . . . This augury affected me. I lay down, but I was unable to sleep. I got up and walked about for a while, looking at the immense line of fires that covered the heights beyond the village of Cheverino.

15. The PLUPERFECT INDICATIVE and the PAST ANTERIOR OF THE INDICATIVE are both rendered by the same English form—*viz.* : had + past participle: *j'avais donné* and *j'eus donné* both mean I had given. But the pluperfect merely indicates that, at a point of time now past, an action had already taken place, whilst the past anterior presents one action as immediately preceding another. They are usually preceded by "when," "after," "as soon as," "hardly," "no sooner"—*quand, lorsque, après que, dès que, aussitôt que, ne . . . pas plus tôt . . . que*:

*J'avais terminé mes affaires quand vous partîtes*, I had finished my business when you went away.

*Quand j'eus fini je sortis*, When I had finished I went out.

16. The FUTURE expresses that something will take place, and is equivalent to the English "predictive future"—I shall give, thou wilt go, he will write. To express the "promissive future," in which "shall" and "will" are

“notional verbs”—I will speak, you shall go— independent words must be used: *Je veux parler, il faut que vous alliez.*

The future must never be used after *si*, if:

*Il nous écrira s'il a besoin de nous.* He will write to us if he has need of us.

In English the present frequently occurs instead of the future, after “when,” “as soon as,” and similar expressions. In French the future must always be used:

I shall speak to him when I see him, *Je lui parlerai quand je le verrai.*

#### EXERCISE XXIV.

1. Bears (*ours*) climb up (*grimper-sur*) trees.
2. The sun shines (*briller*) for everybody (*tout le monde*).
3. The earth refuses (*refuser*) nothing to those who cultivate (*cultiver*) it.
4. Railways have contributed (*contribuer*) to the progress (*le progrès*) of commerce.
5. If he lends you his book do not forget (*oublier*) to thank (*remercier*) him for (of) it.
6. We have been working for more than an hour.
7. He who has not tilled shall not reap (*récolter*).
8. You will regret (*regretter*) not having (to have) spoken to him.
9. They prevented me from entering (*entrer*).
10. Your parents desire that you should work assiduously (*assidûment*).
11. I had been waiting two hours for him when his letter was brought me.
12. The siege (*siège*) of Troy (*Troie*) lasted (*dura*) ten years.
13. If I dared (*le*) I would ask him to lend me twenty francs.
14. He told me (that) he would explain (*expliquer*) that rule to me.
15. When we had finished (*achever*) our work, we went (*allâmes*) and played.
16. I told him yesterday that I should come (*viendrais*) and speak to him to-day.
17. He never meets (*rencontre*) us without borrowing (*emprunter*) money from us.
18. I would not have given him anything if he had not looked so wretched.
19. Do you think(that) your father will come back (*rentrer*) before twelve o'clock?
20. I wish (*souhaiter*) (that) he may give you what you have asked him (for).
21. The dictionary is on the table; consult it.
22. Beg him to come in.
23. Ask your friends what they think of you.
24. Does your brother speak French as well as you?
25. It is difficult to overcome prejudice.
26. Would your friend dare to speak to them if he were to meet them?

#### KEY TO EXERCISE XXIII.

Ceux qui méprisent les petits défauts ont bien tort. Le plus petit ennemi est toujours assez grand pour être dangereux. Ce ne sont pas les éléphants qui causent la perte des moissons et la perte des laboureurs; ce sont les sauterelles et les petites chenilles quand le blé est en herbe; les charançons et autres insectes imperceptibles quand il est mûr. Ce ne sont pas les gros voleurs seulement qui dépouillent la treille et le verger de leur fruit, ce sont les petits aussi, les moineaux, et même les mouches. Sans être mortels, les petits maux sont quelquefois des ennemis aussi insupportables que les grosses maladies dont nous avons peur. C'est presque toujours par de petits maux négligés que les grands arrivent. Demain le petit rhume d'aujourd'hui sera peut-être une fluxion de poitrine. Sans les petits défauts il n'y aurait pas de vices. D'ailleurs un petit défaut n'est pas une petite chose, et où il y en a un il n'y aura jamais de chef-d'œuvre. Une verrue n'est pas bien grosse, mais si vous l'avez sur le bout du nez, ce sera pour vous une cause continuelle d'ennui et de contrariété. Un petit défaut n'est jamais de petite importance s'il est permanent. Ce qui est durable n'est jamais petit. D'ailleurs un petit défaut est toujours le commencement d'un grand; les vices eux-mêmes sont les enfants des petits défauts. Le petit défaut sera bientôt grand; où il y en avait un il y en aura bientôt plusieurs. Un petit défaut n'est jamais seul. Il a toujours une famille. Si ce n'est point pour lui, c'est pour sa postérité qu'il est à craindre. Vous avez une dent qui a un petit point noir. Ce n'est rien; mais si vous le négligez, ce sera bientôt toute la dent qui sera gâtée. Après celle-là, ce sera la voisine, puis la voisine de la voisine, et le petit point noir que vous avez négligé vous aura coûté plusieurs dents. S'il y a une prune pourrie dans un panier de prunes, toutes les prunes seront bientôt pourries. Le voisinage d'un petit défaut n'est jamais indifférent. La vanité semble être un petit défaut; mais c'est un petit défaut qui a une bien vilaine progéniture. Elle a pour fils le mensonge, qui, malheureusement n'est pas son seul enfant. Elle a en outre deux filles, qui sont la jalousie et l'envie. Parmi leur postérité ils auront la haine, qui sera à son tour la mère de bien des crimes. C'est à cause de leur ténuité même que les petits défauts sont si dangereux. S'ils n'avaient pas l'air si innocents, nous en aurions peur, nous serions sur nos gardes contre eux. Soyez indulgents aux petits défauts de vos amis si vous n'êtes pas à même de les réformer; mais aux vôtres, qui sont toujours sous votre main, soyez implacables.

page 3001

## By P. G. Konody and Dr. Osten

**LIX. COMPARISON OF ADJECTIVES** (continued from LV.). In the comparison of predicative adjectives and corresponding adverbs of manner (which are not subject to declension) the superlative is formed with *am* (contraction of *an*

*dem*) and *auf's* (*auf das*). Some monosyllabic adverbs often add the suffix *-ens* (*frät, late, frät-est-ens; früh, early, früh-est-ens, etc.*). Examples: *Der Vogel fliegt schnell*, the bird flies quickly; *der Vogel fliegt schneller, am schnellsten* or

mit Schnelligkeit. Die Sache ist aufs Beste erledigt, the matter is settled in the best way. The adverbs bald, soon, early, and gern, willingly, gladly, form the comparison irregularly :

1. bald, 2. eher, 3. am ehesten.
1. gern, 2. lieber, 3. am liebsten.

1. The comparative of inferiority is formed with the comparatives weniger or minder, less, and nicht so . . . als, not so . . . as, which, of course, precede the adjective, adverb, or participle: Die Linde ist schattig, die Pappel ist weniger (oder nicht so schattig) als die Linde, The lime-tree is shady, the poplar is less shady than (not so shady as) the lime-tree.

The degree of mutual qualities may also be compared by mehr . . . als, more . . . than, and weniger . . . als, less . . . than: Das Haus ist weniger hoch, als es breit ist, The house is less high than it is wide.

2. The superlative is generally used with the definite article. The comparative may be used with the indefinite article, but not the superlative: ein jüngerer Sohn, a younger son; der jüngste Sohn, the youngest son.

The definite article is dropped in the form of the English possessive or Saxon genitive, which the German language has borrowed from the English: Die größte That Nelsons, the greatest deed of Nelson; but: Nelsons größte That, Nelson's greatest deed. The article is also dropped in several adverbial genitives like bestenfalls, in the best case; schlimmstenfalls, in the worst case, etc.; and in names of materials in advertisements, as: bestes Öl, best oil; feinste Seife, finest soap, etc.

The indefinite article is sometimes employed with the superlative if the superiority expressed is absolute. The superlatives allerliebste (in the sense of "most charming") and letzte (last) are absolute, and can therefore be used with the indefinite article: ein allerliebster Mädchen, a most charming girl; ein letztes Mittel, a last means, etc. The plural is, of course, formed without article: allerliebste Mädchen.

3. As in English there are in German several adjectives which, owing to their definite nature, admit of no comparison whatever. Among them are those which denote certain geometrical forms and materials. A three-cornered object naturally cannot undergo any comparison of superiority, as a higher or lower degree of this quality is excluded: eisen, of iron; golden, golden; silbern, of silver; steinern, of stone; dreieckig, triangular; achtzigjährig, eighty years old; künftige, future; doppelt, double; ein-, zwei-, mehrsilbig, mono-, dis-,

multisyllabic; and similar words, of which the positive already expresses the only and ultimate degree of quality. Leer, empty, and voll, full, do not belong to this group, as they admit relative comparison: a hall, for instance, may be emptier or fuller than another.

**LX. SUPERLATIVE FORMED BY CIRCUMLOCUTION.** The superlative formed with am is used relatively (comparatively) with predicative adjectives and adverbs: Am besten ist das Brot, wenn es nicht zu frisch ist, The bread is best when it is not too new. Die Kinder sind fleißig, wenn sie allein sind, aber am fleißigsten im Vorsein des Lehrers; The children are diligent when they are alone, but most diligent in the presence of the teacher.

1. The superlative formed with aufs is generally used adverbially and absolutely, without comparison, thus denoting a very high absolute degree of a certain condition: Ich wurde aufs Beste empfangen, I was received in the best way; ich war aufs Schlimmste gefaßt, I was prepared for the worst; er war aufs Höchste überrascht, He was surprised in the highest degree.

2. Adverbial superlatives with the root-form -st are usual with adjectives ending in -ig and -lich (generally in the absolute sense) denoting politeness, devotion, etc.: ansehnlich, concernedly, urgently, pressingly, ansehnlichst; ehrerbietig, reverentially, ehrerbietigst; höflich, politely, ich bitte höflichst, I beg most politely; sagen Sie mir gefälligst, Will you kindly tell me; zeigen Sie mir gütigst, Will you kindly show me, etc. But besides these there are some adverbial superlatives with -st, which are used in a relative sense: Bringen Sie mir möglichst schnell, Bring me as quickly as possible; sie gab mir die müdest schöne Blüte, She gave me the least beautiful rose, etc.

3. The adverbial superlative formed with -ens is generally used in an absolute sense: ich danke Ihnen herzlichstens (or bestens), I thank you very much; but never ich danke Ihnen herzlichstens, I thank you most heartily, as herzlich is dissyllabic and belongs to the group of adjectives ending in -lich which take the root-form of the superlative with -st: herzlichst.

4. Several adverbial superlatives with -st and the prefix zu are used relatively, the latter being sometimes written separately: zu höchst, highest; zu tiefst, lowest; and sometimes contracted with the superlative: zuerst, firstly; zuletzt, lastly; zumeist, mostly.

5. Several adverbs of place have corresponding attributive adjectives, which are used adverbially in the superlative.

| Positive Adverb |                             | Attributive Adjective |                  | Superlative Adjective used Adverbially |                    |
|-----------------|-----------------------------|-----------------------|------------------|--|--------------------|
| außen           | out, on the outside         | äußer                 | outward          | äußerst                                | utmost, extreme    |
| innen           | within                      | inner                 | inner, intrinsic | innerst                                | inmost, innermost  |
| oben            | above, overhead             | ober                  | upper, higher    | oberst                                 | uppermost, highest |
| unten           | below, beneath              | unter                 | under, below     | unterst                                | lowest, undermost  |
| (hie)nieden     | down, below                 | nieder                | low, lower       | niederst                               | lowest             |
| hinten          | behind                      | hinter                | behind, after    | hinterst                               | hindermost, last   |
| vorn            | before, in front            | vorder                | fore, front      | vorderst                               | foremost           |
| mitten          | in the midst, in the middle | mittler (mittel)      | middle, mean     | mittelfst                              | midst, middlemost  |

**LXI. Irregular Verbs ;** some combining strong and weak elements, some with irregular inflections.

| INFINITIVE |                             | PRESENT TENSE   | IMPERFECT                  |                    | IMPERATIVE | PAST PARTICIPLE          |
|------------|-----------------------------|---|----------------------------|--------------------|------------|--------------------------|
|            |                             |   | <i>Indicative</i>          | <i>Subjunctive</i> |            |                          |
| bringen    | to bring                    | ich bring-e, -st, -t  | ich brachte                | ich brächte        | bring(e)   | gebracht                 |
| dünken     | to seem, appear             | es dünkt  | es dächte                  | es dächte          | dünke      | gedächte                 |
| dürfen     | to have permission, may     | ich darf, darfst, darf; wir dürfen, dürft, dürfen; subj.: ich dürfe   | ich durfte                 | ich dürfte         | —          | gedurft                  |
| fönnen     | to be able to, can          | „ kann, -st, kann; wir fönnen, fönnst, fönnen; subj.: ich könne       | „ konnte                   | „ könnte           | —          | gekonnt                  |
| mahlen*    | to grind                    | „ mahle, -st, -t  | „ mahlte                   | „ mahlte           | mahl(e)    | gemahlen                 |
| mögen      | to be able, like, wish      | „ mag, -st, mag; wir mögen, mögt, mögen; subj.: ich möge              | „ mochte                   | „ möchte           | —          | gemocht                  |
| müssen     | to be obliged, must         | „ muß, -t, muß; wir müssen, müßt, müssen                              | „ mußte                    | „ müßte            | —          | gemußt                   |
| salzen     | to salt                     | „ salze, -st, -t  | „ salzte                   | „ salzte           | salz(e)    | gesalzen                 |
| sollen     | to be obliged, shall, ought | „ soll, -st, soll; subj.: ich solle                                   | „ sollte                   | „ sollte           | —          | gesollt                  |
| spalten    | to split                    | „ spalte, -st, -t   | „ spaltete                 | „ spaltete         | spalt(e)   | gespalten                |
| wissen     | to know                     | „ weiß, -t, weiß; wir wissen, wißt, wissen; subj.: ich wisse, -st, -e | „ wußte                    | „ wüßte            | wisse      | gewußt                   |
| wollen     | to be willing, will         | „ will, -st, will; wir wollen, wollst, wollen                         | „ wollte                   | „ wollte           | welle      | gewollt                  |
| denken     | to think                    | „ denk-e, -st, -t   | „ dachte                   | „ dächte           | denk(e)    | gedacht                  |
| brennen    | to burn, scorch             | „ brenn-e, -st, -t  | „ brannte                  | „ brennte          | brenn(e)   | gebrannt                 |
| fennen     | to know                     | „ fenn-e, -st, -t   | „ fannte                   | „ fenn(e)          | fenn(e)    | gefammt                  |
| nennen     | to name                     | „ nenn-e, -st, -t   | „ nannte                   | „ nenn(e)          | nenn(e)    | genannt                  |
| rennen     | to run                      | „ renn-e, -st, -t   | „ rannte                   | „ rennte           | renn(e)    | gerannt                  |
| senden     | to send                     | „ send-e, -st, -t   | „ sandte                   | „ sendete          | send(e)    | gesandt                  |
| wenden     | to turn                     | „ wend-e, -st, -t   | ich wandte<br>also wendete | „ wendete          | wend(e)    | gewandt<br>also gewendet |

\* Note the difference between mahlen, to grind, and malen, to paint, which follows the weak conjugation.

EXAMINATION PAPER XVI.

- Which elements are to be found in the conjugation of irregular verbs?
- How do the verbs brennen, fennen, nennen, rennen form the subjunctive imperfect?
- How can one form by circumlocution the superlative of predicative adjectives and corresponding adverbs of manner?
- How is the comparison of inferiority effected?  
How are the degrees of mutual qualities compared?
- Why is it possible to use the indefinite article with the comparative, and, as a rule, not with the superlative?
- Which of the two articles is employed with the superlative, and when must it be dropped?
- When is it possible to use the indefinite article with the superlative?
- Which adjectives are not subject to comparison?
- Which adverbs take the root-form -st in the superlative?

EXERCISE 1. Insert the missing verbs:

Der Müller . . . . das Korn. Der Künstler hat  
The miller grinds the corn. The artist has  
das Bild . . . . Hast du den Kaffee . . . . ?  
painted the picture. Have you ground the coffee?  
Wenn ich nur mit euch gehen . . . . ! (Er . . . .  
If I only could go with you! He must  
heute gehen. Das Haus . . . . Der Vater . . . .  
go to-day. The house burnt. The father bought  
die Geschenke für die Kinder. Warum . . . . ihr  
the presents for the children. Why did you know  
nichts? Ich . . . . nicht spielen. Sie  
nothing! I was not allowed to play. She  
. . . . nicht daran. Die Köchin . . . das Fleisch.  
did not think of it. The cook salted the meat.  
Das Fleisch war nicht . . . . (Er . . . . ihr Blumen.  
The meat was not salted. He sent her flowers.  
Was hat er ihr . . . . ?  
What has he sent her?

EXERCISE 2 (a). Change the following comparatives into positives and superlatives:

Ich werde lieber zu Ihnen kommen. Es ist kühler  
I shall prefer to come to you It is cooler

im Garten. Er veranstaltete Alles besser.  
in the garden. He arranged everything better.  
Unsere Pferde liefen schneller. Die Rose roch  
Our horses ran faster. The rose smelt  
süßer. Er zielte genauer.

more sweetly. He aimed more precisely.

(b). Change the following comparatives into superlatives:

Er war ein jüngerer Sohn der Familie. Wir waren  
He was a younger son of the family. Wo were  
gleichere Schüler in unserer Klasse. Ich sitze  
worse pupils in our class. I am sitting  
unter einem schattigeren Baume. Erzählen Sie uns  
under a shadier tree. Tell us  
eine lustigere Geschichte. Er heiratet ein  
a jollier story. He marries a  
reicheres Mädchen.  
richer girl.

(c). Change the following sentences into the form of the English Possessive:

Der siegreichste Feldzug Napoleons.  
The most glorious campaign of Napoleon.  
Die schönste Zier des Menschen ist die Bescheidenheit.  
The most beautiful adornment of man is modesty.

Das edelste Tier des Waldes ist der Hirsch.

The noblest animal of the forest is the stag.

(d). Insert the missing superlative suffixes:  
Ich danke Ihnen best. . . Ich danke Ihnen  
I thank you [in the best way]. I thank you  
herzlich. . . . Grüßen Sie ihn schönst. . . .  
most heartily. Give him my kindest regards.

Ich empfehle mich ergeben. . . .

I am your most obedient servant

(I recommend myself most obediently).

KEYS TO EXERCISES IN EXAMINATION PAPER XV.  
(PAGE 3064)

EXERCISE 1 (a). Der Fisch ist breiter. Das  
Seil ist dicker. Der Wein ist feiner. Die Rose riecht  
herrlicher. Wir kauften schönere Blumen. Er sah

trauriger aus. Der Himmel ist düsterer. Der Baum  
ist kahler. Das Schloß war loser. Mein Pferd ist  
edler. Mein Pferd ist von edlerer Abstammung.  
Er sandte mir einen finsternen Boten. Ich sah ein  
schlankeres Mädchen. Die Kerze brannte heller. Mein  
Pferd ist weißer, und Ihres ist gelber. Bessere Leute  
findet man selten.

(b). *Comparative*: Das Pferd läuft schneller.  
Die Sonne Italiens scheint heller. Ich wohne näher.  
Der Ton klingt reiner. Das Kind lernt fleißiger.  
Der Ballen steigt höher.

*Superlative*: Das Pferd läuft am schnellsten.  
Die Sonne Italiens scheint am hellsten. Ich wohne  
am nächsten. Der Ton klingt am reinsten. Das Kind  
lernt am fleißigsten. Der Ballen steigt am höchsten.

(c). Dieses Kind ist das eitelste (or am eitelsten).  
Die Straße war die ebenste (or am ebensten). Die  
Gesellschaft war die fröhlichste und heiterste (or am  
fröhlichsten und heitersten). Der tiefste Brunnen war  
auch der breiteste (or am breitesten). Man muß am  
vorsichtigsten sein, wenn etc. Der Turm ist der  
höchste (am höchsten). Das höchste Haus kostet am  
meisten. Ich habe das beste Pferd gekauft. Der edelste  
Wein schmeckt am besten.

(d). Ich bin so groß wie du. Ich bin größer als  
du. Sie sind so liebenswürdig wie Ihre Schwester.  
Sie sind liebenswürdiger als Ihr Bruder. Dieser  
Schüler ist weniger fleißig als jener, obgleich er so alt  
ist wie er. Das Haar des Mädchens war licht wie ein  
Kornfeld. . . . . lighter than a cornfield.

EXERCISE 2 (a). Ich war der Fünfhunte in der  
Reihe. Der Offizier las zuerst den dritten Namen und  
dann den achten. Es war am einundzwanzigsten Mai.  
Auf welchen Tag der Woche fällt der erste April?

(b). Ein halb; ein Drittel; ein Viertel; ein  
Fünftel; ein Sechstel; ein Siebentel; ein Achtel;  
ein Zehntel; ein Zwanzigstel; ein Dreißigstel;  
ein Vierzigstel.  $1\frac{1}{2}$ ,  $4\frac{1}{2}$ ,  $3\frac{1}{2}$ ,  $5\frac{1}{2}$ ,  $2\frac{1}{2}$ .

*Continued*

### TYPICAL LEATHERS, SHOWING VARIOUS GRAINS

A. Printed grain on mod. skin—morseo. B. Calf skin printed to imitate crocodile. C. Printed grain to imitate pig skin. D. Grain side of calf skin in the "crust" (see, as taken from the tan pit). E. Grain of goat skin in the "crust". F. Grain side of calf skin after buffing or scraping. G. Grain side of calf skin after buffing, smoothing, dyeing, and finishing. H. Split flesh side of same piece as G. I. Grain of kip, boarded to increase markings. J. Grain of crocodile or alligator. K. Printed grain to imitate serpent. [See LEATHERS]

# 1 DRESSING LEATHER

Finishing Sole Leather, Currying, Splitting, Boarding, and Graining. The Tools and Processes. Distinctive Features. Imitation Graining of Leather

Group 20  
LEATHER

4

Continued from  
page 3188

By W. S. MURPHY

**Finishing Hard Sole Leather.** The object aimed at by the finisher of sole leather is to preserve weight, while giving the butt smoothness, density, and clean grain.

Different tanners adopt different methods, and it would serve no purpose to detail all those processes minutely. However effective may be the special features of the process devised by one or another, the main lines of treatment are all that really matter. Another difference, and a very important one to the practical workman, is the degree in which machinery is used in the tan-work. In many of the older and smaller tanneries, the workman will find no machinery employed in the finishing of sole leather. As hand work generally follows out the root principle of an industrial operation we shall take it first.

The butts are taken from the layer pits, and allowed to drip free of superfluous liquor, then laid over a stool with a rounded beam for its top, named the *horse*. Now the workman takes a smooth, heavy stone, and rubs all over the leather, his object being to draw the fibres closer together while smoothing the surface. He next applies heavy brushes, full of water, strenuously rubbing till the leather seems as hard and smooth as a sheet of plate glass. This has taken out the *bloom*, and now a layer of oil is lightly brushed on the grain side, and the leather is set aside to dry. When dried to a soft degree, the batch of hides is laid in a pile and left to season or temper. Care must be taken not to let them heat or dry too hard.

Next, the tanners take the hides, and *pin* or *strike* them with a two-handed tool having three blunt edges. By means of the strikers the grain of the hides is flattened out till not a vestige of the pores of the hair roots remains. Again dried, the hides are pinned again, and then put under—first a light brass roller, and then a heavier one. Where machinery is not used a very primitive and simple method of rolling is adopted. The bench is a low table covered with zinc, and on it the hide is laid. Two men, each holding a handle of a brass-covered roller, slowly roll the hide down. Next, they fix the roller under a box, full of heavy stones, and, with this weight on it, run the roller over the hide. When rolled smooth by the machine [14], the leather is hung up in the drying room, and left there to dry for a week or two. Brushed hard to remove superfluous frays and fringes, the leather is sent to the market.

**Machine Leather Dressing.** Hand labour is seldom the only instrument of production in modern tanneries. At one point or another, even the most conservative of manu-

facturers begins to utilise machinery. Among the first machines to be used in this country was the machine now known as the *offal roller*. The bottom part is a broad wheel, set in a strong base, and over is geared a bracket holding a thick little roller, capable of being heavily pressed down. Laid on the broad wheel, the hide can be rolled as lightly or as heavily as may be desired. For "striking," too, the tanner has adopted machinery [13]. This tool can be utilised for striking and sleeking. In the centre of the machine a wooden cylinder rotates under the mechanism of the stones or rollers, while on a table in front rests the hide operated on. At the side the long arm is driven by a powerful crank, and it moves on guide rods from which depend the handles on the wrists of which the rollers, stones, or brushes are fixed. The butt is laid on the wooden cylinder that rotates slowly, while the stones rub swiftly to and fro, and strike it down to the proper smoothness. Supplementary of this tool is the double-bed butt-roller, geared under a heavy bridge, the roller driven by an endless chain. The pressure may be regulated to any weight. Hides passed under this roller have a uniform regularity of surface only to be equalled by the work of the most exceptionally skilled craftsmen.

**The Currier at Work.** If we look at two pieces of leather, the one stiff and horny, grained over like the epidermis of a wild boar, the other smooth and flexible, glassy and soft, we may think these two things, so different in appearance, must have had origins widely different; but it is not improbable that they came from the hide of the same animal or from hides exactly similar. The difference is wholly the creation of the currier's art. Of course, there are organic differences in hides; you could hardly get lambskin out of the hide of a rhinoceros.

As may be inferred, the currier's work covers a wide field. He deals with all classes and kinds of hides and skins, and produces an even wider variety of leathers. This tends to separate him from the tanner. Generically, the two trades were one; but the currying business has developed to such an extent that no tanner can take his place in the currying shop without training. Currying, indeed, may be a separate business, though, as a rule, it is a department of the tanwork.

The currying trade produces a wide variety of work, and, looked at from that point of view, it seems a bewildering maze in which a learner may lose himself; but in reality it can be resolved into a few simple divisions, each one following on the other in regular

## LEATHER

succession. The main lines of the trade are clear and definite, and can be followed straight through from start to finish.

### Shaving, Scouring, and Sleeking.

A great many roughly-tanned hides come to this country from South America, South Africa, and Russia, and these go directly into the hands of the currier. If he can deal with them, he has a good grip of his trade. In fact, the foreign hide is the best school for the currier. Home hides are usually carried to the currier in such condition that he has simply to put them through, and be done with them. Not so with the South American hides; one must acquire a good knowledge of tanning, and understand the qualities of leather, before he is able to deal successfully with these rough-tanned hides. It is better, therefore, to begin with them. After being softened in the usual way, by the application of water, the hides need first to be shaved [9, page 3164]. Until one of those hides has been inspected it is difficult to realise what an irregular thing a bullock's hide may be. It is all patches and knots like a piece of badly-woven cloth. The currier lays the hide over a tall block of wood, almost upright, but angled toward himself, and applies a sharp shaving knife to the surface. Leaning over, he pulls up the two-handled blade, cutting away all outstanding irregularities. The tool-maker has been busy in the currier's behalf, and for every hand operation already described, we have to give an account of a machine. The commonest model of a mechanical shaving tool is a double jaw, the lower jaw holding a roller on which the hide rests, and the upper jaw brings down the spiral shaving knife on it. Holding the hide over the roller, press the treadle-clamp with the foot, sending the hide against the spiral knife that runs round and shaves away as much as is required.

**Hand Scouring.** In some cases, the scouring precedes the shaving; but that is a practical detail which must be determined by circumstances. Hand scouring is very hard work. The scouring stone [15C] is embedded in a wooden handle, and on the back of the handle is a belt into which the hand is slipped. On the heavy table the hide is laid, and the workman scrubs it with the stone, smoothing and pressing, working the fibres together, clearing away wrinkles and all the loose fibres. Next he takes hard little brushes, strapped on his hand as the stone was, and diligently scrubs till the leather is one fine, smooth sheet.

### Stoning and Brushing Machines.

Here, again, our friend the inventor comes in, and this time with a welcome. In nearly every currying works of any size, the stoning and brushing machines are installed. We have seen several kinds, but all work on the same principle. The earliest scourer and one likely

to be met with in small, old-fashioned works, is shaped like a wall crane, the jib extending over a table, having within it, instead of the chain, a double-jointed piston-rod, at the end of which is a wrist joint, holding either stones or brush. This machine has been vastly improved, and made almost automatic. The old

machine, it is obvious, requires a man in constant attendance; but one worker can attend to four of those new machines [16] without trouble. From the base of the crane comes out a frame holding the table for the hide, and swivel and turning gear, all supported on a wheel in front. While the tremendous arm sweeps stones or brushes along its surface, the position of the hide is always being shifted,

thus giving its whole surface to the work without the intervention of a human finger.

**Special Treatment of South American Hides.** The roughly-tanned hides of South America sometimes need another tanning, just to make sure of them. Fine leathers, too, are given a short bath in warm sumach at this stage. The currier performs this work by drumming, putting the hides in a large drum with strong tanning liquor, and giving them a run for from four to six hours. When taken out and cleared of superfluous liquor, the hides are sleeked. This may be done in a variety of ways. You may put them under a mechanical scourer armed with a roller in place of the stones, or give them a round of the striking machine used for sole-leather. Artistic

13. STRIKING-OUT MACHINE

14. ROLLING MACHINE

workers prefer the hand sleeking, done on the stone tables, with blunt steel blades. The hand sleekers certainly make the best job, but except for high-class harness or upper boot leathers, the cost is greater than the added value represents.

**Need for Currying.** If leather were used only for soles and heavy belts the stiffness

would not matter ; but we imagine that the wearing of boots would quickly cease to be fashionable if all leather were stiff and hard. Our theory is this. Though, by scouring, sleeking, bending, and other operations, the tools for which are shown in 15, it is possible to reduce the stiffness of leather by a considerable degree, the hardness and lack of elasticity remain, and must be overcome. The fibres of the leather are opened, but to make them supple they need oiling. The bearings of your bicycle move freely enough for merely mechanical purposes, but you oil them, so that the metal will not rub, and give you an elastic smoothness in the working of the machine. In leather the same principle acts. By covering all those little fibrils with oil, you make them move easily and without friction upon each other. Moreover, oil has the power of keeping out water, and by currying, the waterproof quality of leather is greatly improved.

**Stuffing Materials.** Mechanical stuffing has not been very generally adopted in this country, though the practice is coming more and more into vogue for leathers produced in large quantities from one class of hides. Even if hand stuffing were to be greatly superseded, the learner would do well to acquire the art, because it gives healthy training to the muscles, and reveals, as nothing else can, the true character and meaning of the process. The stuffing material is called *dubbin*; the best dubbin is composed of tallow and cod-liver oil. Materials less costly are frequently used, and adulterations of cod-liver oil are too common. Ordinary fish oils, cotton-seed and other vegetable oils should be avoided, because they produce a defect technically known as *spueing*, appearing at first as resinous pimples on the surface of the finished leather, and growing over the whole surface. Other oils and greases, such as vaseline, neats'-foot,

table, and taking a slake of dubbin, the workman spreads it a little with his hand, then works it into the surface of the leather with the fleshy part of his forearm. Strength and dexterity are needed for the work ; but the great point in this, as in all crafts, is for the worker to lay himself out for it. The diletante currier makes a poor shape at stuffing ; but the willing worker soon acquires the art—and big muscled biceps. Bit by bit, the whole hide is covered, and then hung up to dry.

**Drum Stuffing.** Mechanical stuffing presents many difficulties, the leading problem being to find a substitute for the intelligently directed forearm of the currier. A form of scouring machine has been adapted to the purpose, a spreading roller taking the place of the scouring stones, and the device answers fairly well, the currier supplying the grease, while the machine does the hard work. But this idea did not meet the unqualified approval of the flying genius of American industry. The American currier solved the problem by melting the grease, so that by mechanical beating and immersion the leather could be stuffed. The stuffing drum differs in important respects from the tanning drum. The axle is a hollow

16. SETTING AND SCOURING MACHINE

sperm, and paraffin, do not produce that defect, though in some cases all these call for special precautions. Tallow and cod-liver oil, brought to a fine pasty grease, make the best dubbin.

**Hand Stuffing.** The skins, still wet from previous treatment, are laid on the stuffing

## LEATHER

tube, through which the melted dubbin is fed, and the motion given is by a small pinion wheel running on the toothed rim of the drum. In internal arrangement, too, the stuffing drum would be if put to the job. The drum must be kept at an even temperature of about 60° C., and to effect this various devices are adopted—by a steam coil inside the drum, hot-air fans, and so on. The drum is set rotating, and the grease runs in through the axle tube. As the leather wheels round, it greedily takes in the grease. In about 30 minutes the stuffing is complete, and the hides are taken out. It must be admitted that drum stuffing is not so satisfactory as hand stuffing; but even that defect is somewhat mitigated by the inventive brain, for the hides are sleeked warm, the sleeker knives helping to spread the grease into the parts not already permeated.

**Sleeking.** Once again the hides are laid on the boards, and this time to be finally sleeked. With his blunt steel blade the currier works all over the surface of the leather [18], smoothing down the fibres and squeezing out the stuffing the hide could not absorb. It is astonishing the amount of fat the sleeker takes from a hide that seemed to the outward appearance as dry as bone. This grease is said by authorities to be the hard fats which failed to combine with the oil. It is collected, and put back again for further use as dubbin, with a little addition of oil. The practice of setting-out by machine [20] is on the increase.

**Whitening.** The hide is smooth, but not yet smooth enough to satisfy the leather user. Different kinds of leather are given different treatment; but we, faithful to our principle of keeping to the simplest first, will follow the common grades of leather. These are subjected to a process called *whitening*, and whitening it is. On a table of marble or smooth slate, the hide is laid flat, and the whitener goes over it with his knife. This is a curious and formidable weapon. A steel blade, 5 in. long by 6 in. broad is fixed in a rounded handle to fit the palms; the edge being keen and finely tempered. Holding it steadily with both hands, the whitener makes the blade sweep curvingly over the hide, taking off a clean

shaving at every stroke. Smooth as the hide was before, it is smoother now, and not a knife-mark is visible.

**Splitting.** The splitting of the hide or skin may be done at any stage of the tanning process. Some tanners split the hides raw, others split sheepskins and calfskins after liming; but the practice most common in this country is to do the splitting just before finishing. By this means, it is contended, you get all your tannage and currying done at once, and thus save time. There are other considerations, but we do not propose to discuss a controversy which is certain to be settled by each man for himself. Few more ingenious machines have been contrived than this leather-splitting knife [15X]. We have repeatedly called attention to the fact

that all hides vary greatly in thickness; even the smallest section of a hide tapers in one direction or another. It is easy to split a material of uniform thickness, because the knife, if properly guided, will travel on one plane; but in this case it would seem that the knife must vary its plane with the varying thickness of the hide.

**Splitting Machine.** Let us see how the problem has been solved. The splitting machine consists of three rollers [page 3165], running one above the other, in front of an endless band-knife, the cutting section of which almost runs between the two upper rollers. The two higher rollers are brass, and the roller below is covered with indiarubber. But the middle roller is divided into small sections, seeming rather a series of bands than a roller. Set the knife agoing, and feed in the leather. As the hide goes in between the sectioned roller and its solid complement, it presses down upon the rubberroller. A thicker part of the hide comes in the centre, but the uppermost roller yields not a fraction. The sectioned roller yields,

Photographs taken in Elswick Leather Works, Newcastle

and the rubber, while letting it sink to the depth required, holds it level, so keeping the hide on an equal plane and carrying it forward to the knife. With this tool the leather manufacturer can split hides into sheets thinner than tissue paper.

**Boarding, Blacking, and Glassing.** Even after all our trouble, the stubborn bullock hide shows an inclination to stiffness, and

threatens to show the marks of bending if you attempt it. This stiffness must be removed and the leather man has adopted the very sensible device of working the hide into the habit of bending and turning. This process he calls **boarding** [19]. Holding in one hand a convex piece of cork-covered wood, the workman bends and turns the leather on the table, smoothing the surface the while with his tool, giving to the hide that peculiar grain which distinguishes all natural-coloured flexible leathers. In reality, those crinkles are like so many hinges for the fibres of the hide. In fine leathers this grain must be kept almost invisible, and the boarding needs to be dexterously done. This, however, is a quality which can be acquired only by practice.

For tan boots, harness saddles, and many other kinds of goods, the leather is finished in its natural colour; but most boots worn have black tops, and black leather is used for a vast variety of other purposes. The blacking is a very simple process. Having mixed well a compound of cod-liver oil and vegetable black, the workman takes his brush and spreads the colour on the leather; it dries in, a deep dull black.

However good that dull leather may be, it would hardly sell in the market. You have to put a kind of polish on it. Owing to the oil in the compound the polishing is easy, and yet quite permanent. Some large firms employ glass rollers, but hand glassing is common. With a thick piece of plate glass, rounded at the sides, the leather is rubbed till it takes on a smooth, soft polish.

As promised at the beginning of this section, we have followed the commonest of dressing for upper leather to its finished state, and allowed the other qualities to pass. We must now return, and learn what is done with them.

**Graining.** The machinist has taken full possession of the finishing-room of the leather factory. The old tanyard may be still going on in the same

watery, liquory way, and the curriers scour and stuff by strength of arm; but the finisher demands power-driven machines to aid him in coping with the demands of the market.

Strange fancies are conjured up in the minds of the masses by adventurous slipper-makers and purse manufacturers; young men desire alligator-hide slippers, and young ladies seek to possess crocodile-skin purses, without the money to buy them. But the imitation article will please an imitative fancy, and so the leather manufacturer bids his finishers change the hide of the mild cow into the semblance of a crocodile's skin. The thing is very simple if only you have learnt the secret. Graining machines are of many patterns, and to describe the methods of working them all would be tedious, and serve little purpose. A common form of graining press is not unlike a die-stamping machine, with a base that moves automatically. Another form [17]

is an adaptation of the currier's mechanical scourers, with roller dies instead of stones or brushes. Under the roller the leather is laid, and the long arm goes to and fro, at every stroke

leaving the deep mark of the pebble or pigskin on the surface. Whatever the form of the machine, the workman has to watch that the grain is regular and clean. Irregular graining may escape the eye of the average man in the street; but the shoemaker will quickly detect careless work.

#### **Printed Grains.**

The mechanically printed grains are usually good copies of natural grains, and are very deceptive when made into articles. Some are printed on the flesh splits, but those on the grain or grain splits are to be preferred. The markings are very interesting, and some reproductions from photographs taken from actual leathers are shown on the plate

20. SETTING-OUT BY MACHINE

facing page 3217. The printed grains are made with dies taken from the leathers by electro-process.

## THE FINANCE OF LIFE

How to Save Money and How to Use It. The Place of  
Thrift in Life. Insurance. Friendly Societies. Mortgages

By C. DUNCAN CROSS

OUR education, we have agreed, is of little or no use to us unless we apply it to the daily working of our lives; and though it is not the business of education to make us unduly anxious to become rich, education should teach us to be careful in all things. It may seem that unnecessary emphasis is laid on the maxims which enjoin the saving of money as one of the guiding principles of life; but thrift has its lawful place in all our lives, and is, indeed, in every successful and properly conducted life a factor of great importance.

"What is the importance of thrift?" is often asked. "Why should I hoard money which I may never need, and deny myself things I really want now. If one goes on preparing for the rainy day, one may die before it comes. Money was made to be spent, not to be saved."

True. Money was made to be spent—but to be spent wisely. It is here that most people fail. The difference between "I need" and "I want" is one of the least understood things in the English language.

**When to Save and Why to Save.** Save all your life, from the time you begin to earn, from the time you begin to receive presents. If you have not already begun, start to-day. Whatever your income, put aside as large a proportion as possible for the time you may need it. The young man says, "I have no ties, no responsibilities; why should I save?" The reply is that some day he will marry—he will have a host of expenses to meet which will interfere with his saving. On the other hand, if he never marries he must provide for a lonely old age, when he will need all his money to compensate him for the lack of a home and family.

Besides, the man with a little capital is always worth more than the spendthrift with none. Is there a small business going cheap? You may become your own master. Is there a plot of desirable land to be sold for a song? You may double your capital by judicious investment. A man with a little money who is out of work can look about him, pick and choose, take a partnership, while the spendthrift must take the first thing that offers. Beyond all this is the solid sense of satisfaction through life that there is something at your back, something for an emergency; and this feeling alone is worth all the little sacrifices it may be necessary to make.

The beginning of thrift is the keeping of a strict account of all household and personal expenses. For a time, at all events, this account should be balanced daily, and a thoughtful review held of the day's expenditure. The fact which presents itself first of all in the personal accounts is the enormous amount of money spent on trifles which have no practical value

and give no adequate satisfaction for the money spent on them.

It is possible to reduce these items almost without noticing it. Give up the luxuries little by little, and see that the amount saved is put aside, or it will assuredly be spent on something else.

**Household Finance.** In household finance it is equally possible to save. A fixed sum should be laid down as the average of the week's expenditure, and everything saved on this should be put aside into the common fund. Each week should be treated separately and apart. Nothing should be carried forward to the next. Above all, long credit should be avoided.

Since the household of every reader varies with each individual case, it is not possible to lay down any fixed rule of expenditure even for men earning the same income. As a fundamental maxim, however, the rent of the house, the rates and taxes, should never exceed one-fifth of the income, and should, if possible, be kept under that figure. After that let there be an estimate made out of the probable year's expenditure, so much being allotted to housekeeping, including light and fuel, so much to servants, dress, personal expenses, doctor, life and fire insurance, and holidays. In addition, a sum of from 5 to 10 per cent. of the income should be put down for unforeseen expenditure, which always crops up in the form of broken furniture, accidents, extra expenses, and so forth. For two or three years no necessity may arise for spending this sum. So much the better. Save it. But one year you will be glad that you anticipated "Unforeseen Expenditure." On each of these items try to save a little—never mind how little it is. A shilling a week mounts up to £2 12s. in a year, and a shilling a week on several items makes quite a good show at the end of the twelve months.

**Savings Banks.** The money-box is a fine institution too much neglected by grown-ups. Any sum, no matter how small, can be put into a money-box, and when the box grows heavy its store can be placed in the Post Office bank. Any amount in shillings can be deposited, and every pound begins to earn money for itself at the rate of  $2\frac{1}{2}$  per cent., or sixpence a year on every pound.

The Post Office Savings Bank is the finest bank in the world for the man of small means. Money can be paid in through any branch post-office, and a receipt is given for it both by the clerk's signature in the bank-book and by an official notice from headquarters. The bank book must be sent up once a year on or near the anniversary of the opening of the account, and interest at the rate of  $2\frac{1}{2}$  per cent. is added to the amount on deposit. Money can be withdrawn

by filling in an official form of withdrawal and sending it in to headquarters. After three to six days there comes a payment voucher, which must be signed at the post-office for which it is available, the amount being entered at the same time in the depositor's bank-book. If the case be urgent, any amount up to £20 can be withdrawn by writing across the withdrawal form "Payment by return of post." The cost of a telegram and its repetition must be paid in advance, and the warrant is sent off by return of post. In the same way any amount up to £10 can be withdrawn on the day of application by writing across the notice "payment by telegram," in which case the cost of telegrams and repetition each way has to be paid.

Recently a new system has been introduced to meet emergency cases. On presentation of the deposit book, any sum not exceeding £1 may be paid at once to the depositor who presents himself in person.

No more than £50 may be deposited in any one year, and the total amount on deposit with interest may in no case exceed £200. When, however, the account is nearing this figure, the depositor may instruct the savings bank to purchase Government stock, the interest on which, at the rate of  $2\frac{1}{2}$  per cent., will be paid into his account.

Any sum in round shillings is receivable; but for children and those who can only save a penny at a time, there are forms obtainable at any post-office, with divisions marked upon them for twelve penny stamps. These, when full, may be paid in as shillings.

Whilst small economies are going on let us look at another side of the question.

**Life Assurance.** Life assurance may be regarded at once as an investment and as a means of compulsory saving, for on the one hand a life policy is a financial asset on which, should necessity arise, money may be borrowed; and on the other hand, the premiums have to be paid, which enforces the necessity of laying aside a certain fixed amount every year. To a single man assurance is highly desirable; to a married man it is an absolute necessity, and there is no better way of providing for wife and children than by taking out a policy for their benefit. If the policy is "expressed" to be for the benefit of wife or children, it is not subject to a man's debts, and even in case of his dying bankrupt the creditors could not touch it. In addition it may be noted that the part of the income (up to one-sixth of the total income) devoted to paying the premiums is exempt from income-tax.

There are two main divisions of insurance—profit-sharing and non-profit-sharing. If you choose to insure your life without participating in the profits of the office you will pay a smaller premium, but you receive only the sum for which you insure. If you elect to receive a bonus out of the profits, the premium will be slightly higher. The bonus may be used to increase the sum assured, or to reduce the premiums, or it may be taken in actual cash; but this last, from the point of view of thrift, is bad. In recent years a plan has been adopted—called the Discounted

Bonus system—whereby future bonuses are anticipated and used to reduce the premium at the beginning of the policy. If the bonuses exceed anticipations, the sum is placed to the policy-holder's credit; if they fall short he must make good the difference.

**Mutual and Proprietary Companies.** Next you should consider whether the office with which you are proposing to insure shall be a proprietary or a mutual office. The former consists of a body of shareholders who subscribe money for the purposes of insurance, and agree for a consideration—i.e., an increased premium—to share profits with the policy-holders. The mutual office is one in which there are no shareholders, but only policy-holders. Consequently the funds of the society consist only of the premiums paid by policy-holders. Here is the reason for the term "mutual," because the policy-holders really insure one another's lives and divide the profits of so doing among themselves.

With a mutual company, therefore, you get better terms; with a proprietary company, less risk. It may be added, to reassure the timid investor, that not one of the big British offices shows any sign of collapsing within the next two generations, and since all accounts are submitted to the Board of Trade, a check is placed on the business dealings of the office. This, unfortunately, does not apply to offices other than those of the British Isles, which, for the present, will be avoided by the prudent investor.

You will next want to find out the state of the company's finances. Are they sound? Is your company being worked on economical lines? Is its new business increasing or diminishing? While stationary new business is not necessarily a bad sign, a slight steady increase is preferable. Declining business is not satisfactory. All this information and much more is to be found in the "Accounts and Statements Deposited with the Board of Trade in pursuance of the Life Assurance Companies Act, 1870," published by the King's printers.

**Important Considerations.** One or two points should be particularly noticed:

1. Has the society been in existence for more than 25 years? This is of importance, because until 25 years the full death-rate is not experienced.

2. The rate of interest assumed in valuation, and the rate of interest actually earned. If the former is high, or if the latter does not considerably exceed it, the office should be avoided. Three per cent. is a very usual figure, though  $2\frac{1}{2}$  per cent. is more desirable as a "valuation rate."

3. The expenses of management. These should not be more than 18 per cent. of the premium income. Many American offices are notoriously extravagant.

4. What are the investments, and what undivided surplus was put to reserve?

To give some idea of the cost of insurance to the policy-holder the following table may be useful. It shows the *average* annual premiums for whole life insurance of £100. It is obtained by adding together the premiums required by

various companies and dividing by the number of companies included :

| Age at Entry. | With Profits.     | Without Profits.  | Discounted Bonus. |
|---------------|-------------------|-------------------|-------------------|
| 21            | £ s. d.<br>1 19 6 | £ s. d.<br>1 13 8 | £ s. d.<br>1 12 2 |
| 30            | 2 8 9             | 2 1 7             | 1 19 1            |
| 40            | 3 4 6             | 2 15 11           | 2 12 3            |
| 50            | 4 11 6            | 4 0 7             | 3 15 0            |

The premium rate alone is not a sufficient guide to the benefits of a company. A high premium may mean a high bonus; so that both should be considered.

The rates vary, of course, with each individual company. One or two companies offer to total abstainers a discount of between 5 and 10 per cent.

Some companies make a speciality of Industrial Assurance, by which is meant dealing with working men who prefer to pay their premiums by the week rather than by the quarter or the half-year. In addition to what has been said before a word may be added as to this particular branch of insurance. Since one of the great sources of revenue in industrial insurance is from lapsed policies given up by those who could not continue the premiums, it is desirable to insure only for such a sum as can readily be afforded even when times are bad. It is tempting to insure for a large sum when trade is booming; but if trade becomes slack, or the policy-holder falls out of work, the weekly premium becomes a millstone round a poor man's neck. Therefore, insure only for so much as you can pay easily when trade is moderate, and devote your savings in the good years to some other form of investment. Another point is to choose a company which will, if you are unable to keep up the payments, grant you a fully-paid-up policy in proportion to the amount of premium paid. It should be noted that, the expenses of collecting being very great, the premiums in this class of insurance are necessarily heavy.

**Borrowed Premiums.** It is generally possible to arrange with a third party to pay the premiums until you are able to continue them yourself, the policy being held as security, say 5 per cent. interest on the amount he pays. In the event of your death he will recoup himself from the amount due from the company, and the balance will be handed over to your wife and children. There should be some written agreement recording the transaction, or the office may refuse to pay him. Another way in which money may be borrowed is by a loan from the office itself.

So much for the straight-away life assurance; but there is another form of assurance which of recent years has become increasingly popular. This is Endowment Assurance, by which you insure for a certain sum to be paid at death or at a stipulated age. Like most other forms of life assurance, it has its pros and cons. On the one hand, it means that at the time of life when most men are thinking of retiring, there is a

nice little sum of money waiting for use in old age; on the other hand, it does not protect the wife and family from the husband's extravagance. It comes, too, at a time when, perhaps, the man is losing touch with active business affairs, and is not so well able to invest it satisfactorily. The premiums in this class of insurance are naturally higher, because the whole amount must be paid off in a certain specified time, instead of there being the possibility of the man living to old age and paying up to the day of his death.

In much the same class are deferred annuities, for which a certain sum is paid each year in order to receive a fixed income beginning at, say, 55, and continuing to the date of death. These can be arranged through the Post Office or through a Life office doing that class of business. An immediate annuity can be purchased by a man who desires a high rate of interest on his money; but this is the worst form of investment, because the capital dies with him.

**Friendly Societies.** A notable side of working men's thrift is to be found in the innumerable friendly societies scattered throughout the country. An idea of the growth of these societies may be gained when it is stated that the membership of the registered friendly societies is nearly six million, with funds approaching £40,000,000. About £5,000,000 is spent annually by these societies in benefits of various kinds. Friendly societies are closely allied to mutual assurance companies in that the members practically insure one another, and, like insurance companies, they have to be registered under a special act.

For a certain payment per week, the societies guarantee sick pay during a varying period; they pay doctors' bills, funeral expenses, and a sum at death. Some of the societies have a subsidiary benefit fund for relief in specially deserving cases of distress, by which members are assisted to seek employment, or in cases of sickness prolonged beyond the limit specified in the rules. Old age pensions (or, in other words, deferred annuities) may also be arranged for through certain societies.

The three most important friendly societies are the Foresters, the Odd Fellows, and the Hearts of Oak; but there is a vast number of smaller, and in many cases excellently managed, societies. Between the great societies there is little to choose. In joining a smaller society, some little care should be exercised. For instance, in some of the younger societies there was in the past a tendency to treat the members too liberally, with the result that the official actuary has been obliged to step in and call for a revision of their constitution, either by increasing premiums or reducing benefits.

**Advantages of the Larger Societies.** Generally, one is forced to the conclusion that the large society has the advantage over the small society, and that the old-established large society, with its greater experience, and the huge membership which gives it a better average to work upon, is most satisfactory for the working man. It is theoretically preferable

that the society's funds should be administered as a whole, rather than that each branch should be treated as a separate concern, but practically a large old-established branch may be quite satisfactory.

A step lower than the friendly societies are the slate clubs and allied clubs, which, for a certain payment weekly, disburse sick pay to their members and give a sum at death for funeral expenses. Since, however, the residue is shared out at the end of each year, these concerns lack the stability which is to be desired, and they are often badly managed by unbusinesslike people. Unregistered societies are generally to be avoided, because of the obscurity of their legal standing.

**Organised Investments.** Having arranged for the life policy, you will look round for some other avenue for savings. A very general method of employing small savings is by joining a building society. Now, building societies, owing to the amount of fraud which has been associated with their name, have fallen into disrepute of late years; but if the society is run on sound lines by honest men, it is often a most profitable investment. The first mark of an honest building society is that it publishes a balance-sheet, with a profit and loss account. If so, it is safe to make further inquiries, which should be directed towards ascertaining the class of property in which its money is invested. No rules can be laid down; but it will at once be understood that property which is liable to depreciation is a bad holding for a society. For example, of recent years there has been a rapid decline in the value of licensed premises. Any building society which held mortgages on property of this nature would have to write off considerable sums to meet the declining values.

For the man who wishes to purchase his own house, the building society is most useful. It will lend him money on a mortgage of his house, and this he can repay by small instalments, so that in the course of a few years he may become the owner of his house on the most moderate terms possible.

**House and Land Property.** Investment in land or house property is greatly favoured by small investors; but it is a form which may have a good many disadvantages. There are so many factors to be taken into consideration. Chief among these is the question, "Will the neighbourhood in which the property is situated grow, stand still, or decrease in population?" and as to this, only well-informed local opinion can answer. Sometimes even local opinion is at fault through some influence outside the range of conjecture.

Let us imagine a town which has sprung up around a large Government factory employing thousands of workmen. One day the Government may decide to shut down the factory or remove the industry to another part of the country. Such things spell ruin. Another point to be watched is the amount of building going on, and the number of empty houses in the district.

Again, are there more houses than families, or has the character of the district changed, so that the empty houses represent a class of population that has moved away? So many points go to depreciate house property: a factory has begun work, a sports track has been opened, the electric trams have come. "Up go the boards, and down go the values."

As to the class of property to be bought, it may be observed that large property has the disadvantages above-mentioned, but it is generally inhabited by good families, who intend to stay in the neighbourhood. Small property pays better, but there is more trouble in collecting the rents; and small property, especially when it is old, means a large allowance for dilapidations. In the country, or in small country towns, conditions are a little more stable; but here again the town must be growing if the investment is to appreciate in value. A ground rent is an investment that should bring in 4 per cent., but it should be chosen only when the ground rent is not too great in proportion to the rent of the house. One-sixth is a fair average.

**Mortgages.** Mortgages are admirable investments, and as there is some haziness in the lay mind as to what a mortgage really is, it may be well to explain in detail. A man desires to raise (say) £100 on a certain piece of property which your solicitor, after examining the title, approves as security. You agree to lend the money. The mortgagor agrees to repay the money in six months' time, with interest, generally at the rate of 4 per cent. He makes over to you the property, whatever it is, and so long as the hundred pounds is on loan he must pay your interest in regular instalments, quarterly or half-yearly. The "six months" mentioned in the deed is only put in as a matter of form, because although you may not wish to invest your money for six months only, the mortgagor, on the other hand, does not want to part with his land for ever. So the mortgage runs on until one party or the other gives six months' notice of terminating the agreement; if, on the appointed day, the money is returned, the property goes back to the original owner.

A solicitor *must* be consulted as to the drawing up of the deed and for the examination of the title. Should you wish to call in the money, six months' notice that you wish to be repaid must be given, and if the money is not then forthcoming you may sell or foreclose—i.e., dispose of the property.

**Selecting a House.** The following are the main points particularly to be considered in effecting a mortgage. Select the property carefully. In the case of a house, see that it is well built, well situated, and not likely to suffer from a change of occupier. Do not advance more than two-thirds of the value, and always prefer freehold to leasehold. The rate of mortgage interest varies according to the value and quality of the property. On good landed estates it is from  $3\frac{1}{2}$  to  $3\frac{3}{4}$  per cent.; on first-class freehold property, 4 per cent.; on less eligible property,  $4\frac{1}{2}$  to 5 per cent.; on cottage property, 6 per cent.

# HAS SIGHT REACHED ITS LIMIT?

The "Machinery" of Vision. Though Mechanical Inventions Bring the Invisible into Sight, Researches Depending on Vision are Limited by the Nature of Light

By Dr. C. W. SALEEBY

WE have already described the existence in the retina of what are called the *blind spot* and the *yellow spot*. We have also seen that, considered solely from the standpoint of optics, the retina is a curtain or screen—a mere surface upon which certain rays of light are focussed. But to leave the matter here would be to leave a great gap between physics and psychology. The student of psychology is already aware that vision does not take place in the retina. The retina is merely the "end organ" or recipient organ of the visual apparatus. The real eye is in the back of the head. If the optic nerve be severed, vision must cease, and this, even were it possible to maintain the health of the retina after such an accident. Hence it follows that there are in the retina physical or physico-chemical processes which should be studied by us here, since they are immediately determined by light. Elsewhere the present writer has made some allusion to his suggestion that the newly discovered pressure of light may play a part in the excitation of the physical changes which occur when the retina is stimulated.

**Sight Cells.** Entirely ignoring all the less important parts of the retina, let us confine our attention exclusively to those parts which are immediately acted upon by the radiant energy. These are found in the deepest layer of the retina—except for a narrow bounding layer which consists of cells containing pigment that probably has the function of absorbing useless light. The "visual cells," or "rods and cones," form a kind of palisade which the light reaches after traversing the other retinal layers. The rods are much more numerous than the cones, except at the yellow spot. Their complicated structure does not here concern us, except to know that they contain a complex chemical compound of a dark colour which is known as the visual purple. The cones are very different in shape and do not contain this visual purple. On the other hand, it is more than probable that both rods and cones contain certain highly complex chemical bodies capable of extremely rapid decomposition under the influence of light. Many distinguished physicists, such as Clerk-Maxwell, have experimented upon the functions and behaviour of these visual cells. It was at one time thought that the cones alone are really visual cells, but it is now known that the rods are also true terminals, though probably of lower development and older in the history of the race—for if they were not, the images of small stars, for instance, would appear and reappear when the eye was slowly moved. The star would not be seen where the rays from it fell upon the rod-occupied interval between separated cones. Certain other facts may briefly be noted. In

order to obtain two images at one and the same time, it appears that two cones are necessary. Two objects—for instance, twin stars—so small as to affect only one cone appear as only one object. It has been calculated that there are about three million cones in the retina.

**Physical Changes in the Retina.** What, then, are the consequences of the impact of light upon the retina? The first point we may note is that the deepest layer of the retina, consisting of the pigment cells to which we have already alluded, is markedly affected by light. The dark brown pigment of the cells, under the influence of light, runs forwards in between the rods and cones, so that each rod and cone comes to be isolated from its neighbours by an opaque sheath. Further, we note that the visual purple of the rods of the retina is bleached or destroyed by light. Thus the retina, exposed to light, becomes colourless. But this visual purple does not occur in the cones, which are the only visual cells at the yellow spot. The rays which most affect the visual purple are the lower rays of the visible octave and especially the yellow part of the spectrum. It is this part of the spectrum which most affects our eyes, the opposite being true in the case of the photographic plate. So long as the tenth or pigmented layer of the retina is intact, the visual purple is readily reproduced after its destruction by light.

**When Light Falls on the Retina.** In attempting to answer the question, "What is the specific action of light on the retina?" several observers have shown—one of them being Professor M'Kendrick, whom we quote—that "when light falls upon the retina it excites a variation of the natural electrical current obtained from the eye by placing it on the cushions of a sensitive galvanometer. The general effect was that the impact of light caused an increase in the natural electrical current; during the continuance of light, the current diminished slowly, and fell in amount even below what it was before the impact, and that the withdrawal of light was followed by a rebound, or second increase, after which the current fell in strength, as if the eye suffered from fatigue."

Professor M'Kendrick goes on to say that "in all probability the electrical change is an index or symptom of certain physical or chemical changes that occur in the retina." Quoting certain other experiments, he goes on to say: "Thus it would appear that light affects the purple matter of the retina, and the result of this chemical change is to stimulate the optic filaments; if the action be arrested, we may have a picture on the retina, but if it be not arrested, the picture is evanescent; the purple matter is used

up, and new matter of a similar kind is formed to take its place. The retina might, therefore, be compared to a sensitive plate having the sensitive matter quickly removed and replaced by chemical changes; and it is probable that the electrical expression of these changes is what has been above described."

The Weber-Fechner Law is a psychophysical law named after two distinguished German students, which asserts that in succeeding stimulations of any sensory organ the sensational effect does not increase proportionally to the stimulus, but as the logarithm of the stimulus. Thus, supposing the stimulus to be ten, a hundred, or a thousand times increased, the sensational effect will not be ten, a hundred or a thousand times, but only one, two, and three times greater. Now it has long been thought that this law is not a physical law but a psychological one—that it is due to the mind and not to its organs, so to speak. But Professor M'Kendrick showed that "the amount of electrical variation [in the retina] produced by light of various intensity corresponded pretty closely to the results expressed by Fechner's law."

**How Images Remain in the Eye.** We have already briefly referred to the fashion in which impressions made by light persist after the stimulus has been removed. The period of persistence varies. "Thus, the duration of an electrical spark is extremely short, but the impression on the retina is so powerful, and remains so long, as to make the sparks visible." With these facts we may associate the existence of what are called "after-images," which may be "positive" or "negative." If, after looking at a bright light for a few seconds we close the eyes or immediately enter a dark room, we may appear to see the light for a short time. This is a positive after-image, apparently dependent upon the persistence of retinal impressions. On the other hand, if we look at the sun and then at the sky, we seem to see a black sun. This is called a *negative after-image*—the word *positive* being applied to those which remain bright, and *negative* to those which are dark in proportion as the real image is bright. Apparently, negative after-images must be explained not merely in vague terms of fatigue, but by the precise suggestion that the visual substances are used up in the highly-stimulated parts of the retina and cannot immediately be replaced, so that, for a few seconds, these parts of the retina are blind. The light falls upon them, but the substances which it customarily decomposes are not there to be acted upon.

What we have said must be regarded as merely an introduction to the study of the physics of the retina. Nothing has been said of colour, because that is a subject which we have not yet discussed in detail.

**"Thus far and no further shalt thou see."** Before we pass on to another part of our subject, there is one very important and interesting matter which should here be discussed. It is that there are naturally imposed and impassable limits to the possibilities of our vision. It may be that, by means of the microscope and the so-called

ultra-microscope, large molecules or their shadows may be seen, but it may be taken as absolutely certain that no one will ever be able to see an atom, much less an electron. In other words, the revealing power of the microscope is limited by the nature of light. Herein is one of the cases where science deliberately asserts that, in a most fruitful direction of research, the very means which are employed by her impose the restriction "thus far and no further," for whatever developments are forthcoming in the use of the microscope the wave length of light must be reckoned with. The subject has been exhaustively studied by Lord Rayleigh and many other students, and certain very positive conclusions have been reached. It is theoretically possible for two points to be distinguished under the microscope if the distance between them be at least equal to the wave length of the light that is used.

**The Power of the Microscope.** This relation holds with light passing perpendicularly upwards through the object examined, if it be transparent; or reflected perpendicularly from its surface to the lenses of the microscope and of the eye, if it be translucent or opaque. With oblique illumination, the inner limit of vision is reduced to half the wave length of the light employed. Now, a sensitive plate may be affected by rays of wave length too short to affect our eyes, and hence it follows in theory that the photographic method may reveal minuteness of structure which we can never directly see.

From these considerations, which are not open to dispute, it follows that the theoretical limit of vision—that is to say, of distinguishing distinct objects—is determined by half the shortest wave length of utilisable light. It may be at present impossible to say at what point light ceases to be utilisable. It is, at any rate, quite certain that we have to pass some distance upwards from the wave length which has the most marked effect upon the retina. The further we pass upwards the greater will be the difficulties with which we have to contend. We may even pass in theory—the practical limit hitherto obtained will be discussed in a moment—to the remarkable rays which were discovered by Professor Röntgen ten years ago, and which we are afterwards to consider at length. In all probability the Röntgen rays are absolutely comparable with the rays of visible light, and have the shortest wave length that we know; in other words, they constitute the very highest notes of the ethereal keyboard.

**The Röntgen Rays Might Reveal One Eight-millionth of an Inch.** The Röntgen rays, it is stated, are capable of very faintly stimulating the retina. If only it were possible for us to see directly by them, they would afford us the most intimate microscopic revelation possible—that is, by a microscopic examination of an object obliquely illuminated by them. It has been estimated that their wave length is probably less than one four-millionth of an inch, so that by their use two points under the microscope could be separately identified if there were one eight-millionth part of an inch between them. This indicates very approximately the utmost limit theoretically possible. We are not for a moment

asserting that it will certainly ever be more than theory. When we come to study the Röntgen rays we shall see the difficulties involved. The chief reason for estimating the theoretical limit is not by any means that we may suggest its ultimate practicability, but that we may show how remote even this limit is from satisfying the needs of science. But before considering this let us observe what has been accomplished.

**The Most Powerful Microscope.** The extent to which the mysteries of Nature have been penetrated by the actual eye of man has been very greatly extended in quite recent years. It would probably be too much to expect, however, that this rate of extension can be continued. In the case of the microscopic method, as in so many others, advance is very often made in the fashion of the man who paid a debt of a shilling, beginning with sixpence, threepence, and so on. The further one goes the slower is the advance, and the smaller the proportion of each step to the total distance to be traversed. The great steps of science are made much less by improvements in old methods than by the invention of new ones. Nevertheless, the limits of vision have lately been greatly extended. When the *low power* and the *high power* of a microscope are talked about, the first may mean, perhaps, a magnification of fifty diameters, and the second of seven or eight hundred. Then, when one hears of the *highest powers*, one finds that 1,200, or at the very most 1,500 diameters are referred to. But it should be more generally known that really high-power microscopy has advanced far beyond these limits. A year or two ago, at a conversazione of the Royal Society, visitors obtained clear views of certain minute objects under a microscopic arrangement made by Mr. J. W. Gordon, and magnifying no less than 10,000 times. This, it may be observed, was with light of average wave length, not with light near the limits of visibility, so that this figure of 10,000 diameters is, at any rate, definitely within the practical limit of vision that is still imposed upon us.

**The Eye which Translates the "Invisible" into the Visible.** Again, at the conversazione of the Royal Society held on 9th May, 1906, the celebrated scientific instrument makers, Messrs R. and J. Beck, showed a remarkable exhibit which illustrated some of the propositions that we have laid down. Its object was to illustrate the ultimate resolving power of the microscope *with light of different wave lengths*. The object examined was an extremely minute diatom, and the source of illumination was a Nernst lamp, which yielded a brilliant beam of light. This beam—which of course, was compound—was split up by a well-known device into an almost equally brilliant spectrum in such a fashion that any part of the spectrum could be used at will, to the exclusion of the others, for the illumination of the diatom. The apparatus demonstrated that when yellow light was used the diatom was not visible at all, however carefully the instrument was focussed. On the other hand, the details of its structure were perfectly resolved when the green part of the

spectrum was employed. The reader will not need to be informed whether yellow light or green light has the shorter wave length. On the same evening there were shown several photographs of diatoms, taken through the microscope with the employment of ultra-violet light, the wave length of which is, of course, shorter even than that of green light. The reader will probably agree that a special interest attaches to the employment in place of our eyes, which are blind to ultra-violet light, of a substitute eye—the photographic plate—which can see this light and render the results of its vision to us in terms of light which our eyes can see—which translates for us, let us say, the invisible into the visible.

**Use of Oil in Magnification.** One other refinement in the use of the microscope—it is older than those we have just mentioned, but is extremely important. If we did not mention it the reader might be puzzled when he met such a phrase as *oil immersion lens*. When even approximately high powers of the microscope are employed, a drop of clear oil is placed upon the slip of glass which covers the object. The object glass of the instrument is then lowered so as to be actually immersed in the drop of oil. Originally, the method employed consisted in the introduction of a drop of water. This diminished the loss of light which occurred as the rays passed from the coverslip to the object glass, and had various other advantages as well. But now we use a drop of oil, in accordance with the work of the most remarkable man who has ever concerned himself with the microscope, Professor Abbe, of Jena, the scientific adviser to the famous firm of Zeiss. The oil employed is the oil of cedar-wood, which has the same refractive and dispersive powers as crown glass, with the consequence that "the rays issuing at any angle from the upper-plane surface of the covering glass shall enter the plane front of the objective without any deflection from their straight course, and without any sensible loss by reflection." The introduction of the oil, or "homogeneous system," has immensely advanced microscopy, and affords a very conspicuous instance of the advantages which ensue when the highest scientific intelligence is associated with the highest commercial intelligence. In this country we have no parallel instance to the engagement of a great scientist as the servant of a great commercial firm, the affording to him of every convenience for his work, the faithful following of his directions, and the consequent profit to him and to his employers, and, what is far more important, the lasting gain of science.

**Extending the Limits of Vision.** The most recent advance to which we have referred, which is owed largely to the work of Mr. J. W. Gordon, of the Royal Institution, has not yet been applied to any very great extent. The use of these very high powers, so markedly extending the limits of vision, would be of the utmost value in, for instance, the present controversy concerning the bodies produced by radium in bouillon, and known as radiobes. But, indeed, users of the microscope have not yet

realised that powers are accessible actually ten times as great as those which they commonly regard as constituting the limit. It is true that the whole process of observation is extremely complicated and expensive when the most refined methods are employed, but, nevertheless, they should be employed to the utmost, since, after all, "seeing is believing" and has a special evidential value, and since these methods bring us near the very limits of possible sight.

**The Limits of Sight in Science.** We have spent much time upon this subject because the most intimate problems of life and of matter are to be sought for in very small space. There is no such philosophic importance in discussing, for instance, the limits of the telescope as there is in our present subject. It is thus of great importance to recognise that the very nature of light imposes on us a precise limit, and that this limit is very narrowly drawn. Let us, for instance, take the ordinary practicable light, having a wave length of, say, one fifty-thousandth of an inch. At the best, given all other conditions which are absolutely perfect, we cannot expect to do more than distinguish by its aid objects that are less than one hundred-thousandth of an inch apart. For many proximate purposes this is well, but such a power, or even the theoretical power obtainable with Röntgen light, is *nowhere in the neighbourhood* of meeting the demands made by the more ultimate problems of life and matter. It is worth insisting upon that no conceivable advances in science can enable actual vision to reveal these ultimate secrets. We do not for a moment say that they are not in process of revelation by indirect methods depending upon inference and reasoning in general. The point is that by the superlatively satisfactory method of vision these ultimate problems can never be unravelled. Whatever science may do, it cannot alter the wave length of light nor the laws of optics.

#### **"The Material for Amazing Progress."**

Having now discussed as fully as possible the various aspects of the subject of the utilisation of light for the purpose of human knowledge, we must pass on to a part of the subject which is perhaps more interesting than any we have yet dealt with. We shall find in the course of it that the subject of the utilisation of light for purposes of knowledge has, after all, not been exhausted, and, indeed, cannot be exhausted by the fullest possible consideration of the microscope, the telescope, the camera, or, indeed, any of the various optical instruments which we have discussed. For though the physical basis of light is such that, in virtue of the property called wave length, an absolute limit is imposed on our vision, yet this very property of wave length, which puts an absolute bar to our progress in this direction, has itself constituted the material for the most amazing progress and for discoveries and revelations which some of the most distinguished thinkers of the comparatively recent past had deliberately declared to be for ever impossible—a fact from which we should take due warning.

For very many pages, now, we have been discussing facts and instruments which are entirely independent for their study of any particular theory as to the actual nature of light—the facts and properties of the eye and of reflection and refraction are, we may say, almost equally satisfactory for study whether we accept the corpuscular theory of Newton or the wave theory of Young. We noted, for instance, how satisfactorily the main facts of reflection could be explained on the assumption of the corpuscular theory of light. Indeed, it is only at the very end of the long discussion through which we have passed that we have had any real need to assume that light consists of waves.

#### **Waves of Sound and Waves of Light.**

But now we are to turn to facts and phenomena which depend for their production and for their comprehension upon the wave theory of light, and which have led to developments of knowledge that can be described only as amazing. Let us recall, in a few brief phrases, what has already been asserted as to the wave theory. We have seen that the history of the wave theory of light really begins with the discovery of what is called interference, and already we know what that term means, because we have studied it, in some measure, under *sound*.

Now, interference is a common property of all forms of wave motion, and it is worth considering in the abstract before we discuss the actual interference phenomena of light. It does not matter whether, for instance, the waves are to-and-fro waves in air or whether they are transverse waves in the ether. The difference between the wave motion constituting sound and that constituting light is measureless in many respects. But they are both wave motions, and therefore they both exhibit interference, and precisely analogous consequences of such interference. As we have seen, if the waves under discussion be water waves caused by throwing stones into a pond, the result of interference will be to make the elevations of the waves higher when the crests of the two waves happen to coincide and to make the troughs deeper when two troughs happen to coincide. Precisely analogous is interference in sound waves; an exactly parallel thing happens. We interpret the superposition of crests and troughs as increase of loudness, and the mutual neutralisation of waves—caused, as we shall now see—we interpret as silence. Similarly, as has previously been said, Young discovered that there are conditions in which the addition of light to light will cause darkness, and its removal will leave light.

#### **Two Light-waves May Make Darkness.**

The general proposition of interference, as stated by Professor Tait, is this: "When two similar and equal series of waves arrive at a common point they interfere . . . with one another so that the actual disturbance of the medium at any instance is the result of the disturbances which it would have suffered at that instant from the two series separately." He goes on to say: "Thus, if crests, and therefore troughs, arrive simultaneously from the two series, the result is a double amount of disturbance. If,

on the contrary, a crest of the first series arrives along with the trough of the second, the next trough of the first series will arrive along with the next crest of the second—and so on. One series is then said to be half a wave length behind the other. In this case the portion of the medium considered will remain *undisturbed*." In the case of water waves, these facts are illustrated by the tides at the Port of Batsha, the peculiarities of which were discussed by Newton himself. At this place "the ocean tide-wave arrives by two different channels, one part being nearly six hours, or half a wave length behind the other. As a result, there is scarcely any noticeable tide at Batsha itself, though at places not very far from it the rise and fall are considerable."

Precisely the same is true of sound waves. Says Tait: "Two sounds of the same wave length and of equal intensity produce a silence if they reach the external ear with an interval of half a wave length, or any odd multiple of half a wave length." The interesting circumstance is that these facts were known before the wave theory of light was accepted and before the interference of light was demonstrated.

**The Law of Interference of Light.** Allusion has already been made to Lord Brougham's violent attack upon Young in the "Edinburgh Review." Let us now quote a few selected sentences from Young's dignified reply to that contemptible performance. It is to be noted that it was an "argument from analogy" that led Young to the truth, and that is why we have insisted at such length upon the parallelism between the phenomena of interference, no matter whether they are displayed in water, air, or ether.

Having stated that his discovery was due to reflection upon the "beautiful experiments of Newton," and having declared that his law seemed to account for more phenomena than any other law of optics then known, Young goes on to say: "I shall endeavour to explain this law by a comparison. Suppose a number of equal waves of water to move upon the surface of a stagnant lake with a certain constant velocity, and to enter a channel leading out of the lake. Suppose, then, another similar cause to have excited another equal series of waves, which arrive at the same channel with the same velocity, and at the same time with the first." He then goes on to show that in such a case the waves must either reinforce one another, or, if there be an interval of half a wave length, "the surface of the water must remain smooth; at least I can discover no alternative either from theory or from experiment. Now, I maintain that similar effects take place whenever two portions of light are thus mixed, and this I call the general law of the interference of light."

**"Argument" from Analogy.** That Young was led to the truth by analogy is, of course, no exceptional case. The "argument" from analogy has been incessantly used by all manner of men since the time of Socrates, who was its great exponent, and we may be sure it was used before his day as well. The present

subject is perhaps the best illustration of the difference between the safe and the unsafe method of employing the "argument" from analogy. The essence of the "argument" from analogy is this: that because A and B resemble one another in a given particular, they will also resemble one another in some other particular, or in all other particulars. Now, that assertion as it stands is evidently false. It does not follow that because A and B resemble one another in one particular they will therefore resemble one another in *any other particular whatever*. There may be only one point of resemblance between them. Socrates himself did not act on this, however, and thousands of thinkers since his day have been contented to accept the so-called "argument" from analogy as if it were really an argument—really a logical, rational process. (We use inverted commas to suggest the fictitious nature of the "argument.")

**The Limit of Analogy.** But it is nothing of the sort. The very utmost that can be said of the "argument" from analogy is that it is *suggestive*. True, it is unquestionably the most valuable and fertile means of suggestion that we know, and too much importance cannot be attached to it within its own sphere of action. Great poetry and the great discoveries of science provide numberless illustrations of the value of analogy. To perceive obscure analogies is to have a mind of a very high order. The process called the association of ideas is never more wonderful than when a Shakespeare or a Newton or a Spencer perceives the parallelism or analogy between things that would never have been connected together in the ordinary mind. In the case of poetic imagery, there is no need to go any further. A Wordsworth may say of a Milton, "Thy soul was like a star and dwelt apart"; and no sensible person desires, as we say, to press the analogy too far. Two things more different than a soul and a star cannot be conceived. Yet in this case there was *just* the resemblance of solitary grandeur.

**The Value of Analogy.** But in matters of science the all-important thing is that the analogy shall be pressed *as far as possible* before any conclusions are drawn from it. If this be not done (and it is constantly omitted) we arrive at wrong conclusions. It is, indeed, not parodying the process too commonly adopted if we say that because Milton's soul was like a star in loneliness and grandeur, it was therefore, like a star, subject to the law of gravitation. At once we see that the analogy breaks down, or, rather, that it is *only* an analogy. The necessity, therefore, is, having seen the analogy, immediately to put it to an *experimental* test. It may lead to nothing at all, and may really hide the profoundest differences, or it may lead to a great discovery. Analogy merely suggests that because A and B resemble one another on a certain point, it *would not be surprising* if they resembled one another in other points. Now, Young had the wisdom to know how much analogy is really worth, and he therefore put the matter, as we shall see, to the supreme test of experiment.

HISTORY OF ART  
continued from page 3092

By P. G. KONODY

THE art of the Middle Ages may be divided into two periods: the Romanesque and the Gothic. The earlier of the two coincides with the troublous time after the fall of the Roman Empire, when the world power passed to the Northern States, and was essentially of a monastic character. The peoples were engaged in constant war and strife, and the cult of the arts and sciences was almost entirely in the hands of the religious bodies, whose main energy was directed towards the building of churches and monasteries. Thus the Romanesque period was, above all, one of architecture, the other arts being pressed into its service as subordinate adjuncts; and the characteristics of the style which, as the name conveys, was based on the Roman model, can best be studied in such churches and monastic buildings as have escaped decay or destruction.

**The Romanesque Church.** The plan of the Romanesque church is based on that of the early Christian basilica, but the modifications gradually introduced in the plan soon transformed the entire style. The one characteristic feature which is retained through all phases of Romanesque architecture, and which is its chief distinguishing feature from the Gothic, is the round arch. The modifications of the plan include the lengthening of the choir and of the transept to form a cross-shape, and the abolition of the forecourt, or atrium, which is either left out altogether, or reduced to a small vestibule. It is only natural that the simultaneous evolution of the Romanesque style should have taken different forms in the different countries. Thus, in Italy the clock tower remained an independent member of the building; whilst in Germany and France the two spires flanking the main porch, as an integral part of the architectural plan, became the customary device. In the Provence again, under Saracenic influence, the pointed arch was frequently adopted in the place of the semicircular arch.

In early Romanesque times the nave had generally a flat, wooden ceiling like the early basilica, which was first replaced by the barrel vault, and later by plain cross vaulting. This cross vaulting was first introduced in the narrower aisles, and for a long time the difficulties of

spanning the loftier and wider nave were considered insuperable. The nave, being generally of about twice the width of the arches by which it is separated from the aisles, it was found necessary in the vaulting of the nave to carry the "groin-rib" across the width of two arches of the colonnade, so that the vaulting is supported by alternating columns, or rather pillars, since the new conditions necessitated a firmer support. As a result, the harsh contrasts between the supporting and resting members disappeared, and gave way to flowing line and rhythmic articulation. To bring the width of each compartment of the vaulting into harmony with the arches of the colonnade (which had only half the width), a blind arch was frequently imposed over two of the arches, connecting two pillars in a semicircle which had its centre on the capital of the intermediate column [46].

**Columns.** Columns in the Romanesque period no longer followed any rules of proportion, and were on the whole more massive than in the classic period. As regards the capital, the typical form is a fanciful cubic shape which in an ingenious manner establishes a natural passing from the circular shaft to the square architrave. The exterior, too, is marked by its massiveness and preponderance of masonry, in contradistinction to the Gothic church, where the eye is caught by the lace-like traceries of windows, rose-windows, and pinnacles. In Italy, more particularly, the long, horizontal lines of the nave and the lower

44. THE FONDACO DEI TURCHI, VENICE

aisles, which are clearly marked on the exterior, give the character to the building; whereas in Gothic church architecture the eye is carried heavenwards by the perpendicular lines of the spires and pinnacles. The relief ornamentation consists of a conventional treatment of plant and animal forms, whilst the wall spaces of the interior, especially of the apse, are frequently decorated with fresco paintings. For baptisteries and mortuary chapels a circular or polygonal plan was generally adhered to, as during the early Christian period.

**The Leaning Tower of Pisa.** One of the earliest and most imposing works of Romanesque architecture in Italy is the Cathedral of Pisa, with its famous leaning

45. EXTERIOR OF PISA CATHEDRAL.

Brogi

tower and circular baptistery [47]. The plan is of the basilica type, with a nave flanked by two aisles on either side, a transept divided, as it were, into a nave and aisles by two colonnades, and terminating in apses, with the intersection of nave and transept crowned by a cupola. The exterior and the inner wall are built of alternate layers of blocks of white and green marble [45]. The entire exterior is beautifully articulated by colonnades of blind arches on the ground floor, and arcades of free columns on the upper part. The cathedral was built in 1063. The leaning tower owes its deviation of about 13 ft. from the perpendicular, in the first instance, to the sinking of the foundations, which took place in the course of its construction; but this unforeseen difficulty did not prevent the bold builders continuing the work, which has now endured for over eight centuries. In Florence, San Miniato is the earliest and most exquisite example of Romanesque architecture, and is remarkable for its raised choir over a beautifully vaulted crypt. The walls are covered with beautiful marble incrustation in panels and bands of black and white. The interior is covered with an open timber roof decorated with bright gold, green, red and blue.

In Northern Italy the development of the Romanesque style was considerably influenced by that of Central Europe, and the details in particular lead up to the Gothic forms, though the campanile, or clock tower, even where it is not detached from the body of the church, never forms an integral part of the design. Brick was frequently used as building material, and very restricted use was made of exterior decoration. Frequently the articulation of the building, the division into nave and aisles,

is not even suggested on the façade, and the galleries are restricted to the top of the gables and apses. Examples of this style abound in Lombardy and Northern Italy, among the most notable being San Zenone in Verona, San Michele in Pavia, and the Cathedral in Modena. Of secular buildings of the period, the Palazzo Loredan and the Fondaco dei Turchi, in Venice [44], are, perhaps, the most typical examples.

In Southern Italy and Sicily the Romanesque style was grafted by the Norman conquerors on the Byzantine and Mohammedan tradition which had taken firm root on this soil. The result was a curious mixture of a basilica plan, Byzantine mosaics and ornamentation, Saracenic pointed arches, and Romanesque towers, such as is to be found in the church of Monreale and in Palermo Cathedral.

### The Romanesque Period in France.

In France, again, we have to distinguish between the South and the North. The South followed the tradition of classic architecture in construction and decorative detail. Barrel vaulting was extensively resorted to, the vault generally covering the entire length of the nave, whilst the aisles terminated in semi-barrel vaults, which counteracted the thrust of the central vault, leading it to the outer walls. The system necessitated the sacrifice of the clerestory windows and the substitution of strong shafts or pillars for the columns. The chief monuments of this type are to be found in the Provence and the Dauphiné. Avignon Cathedral, St. Sernin, at Toulouse (end of eleventh century), and Arles Cathedral are among the most notable examples. The Romanesque churches of Burgundy and French Switzerland are very similar in plan.

In the North, the cool, bold, and clear spirit of

46. THE BLIND ARCH

the Normans left its impress on the architectural style of this race of conquerors, which is throughout logical and structurally sound. In the place of the barrel vault we find here generally cross vaulting. Two bold towers rise from the front of the churches, and, as a rule, another massive square tower crowns the intersection of the nave and transept. The ornamentation is very simple and almost entirely of linear character—meanders, zigzag lines, and chessboard pattern; but towards the end of the period these motifs were very extensively employed, covering large surfaces on the porches, arcades, and interior walls. A notable example of this Norman Romanesque style is the church of St. Etienne at Caen, built towards the end of the eleventh century.

**Architecture in England and in Germany.** The Norman style came to England in the wake of William the Conqueror, and soon supplanted the earlier Saxon style, from which it adopted, however, the use of timber, especially for ceilings. Vaulted naves of this period are almost unknown. The crossing is generally crowned by a massive tower, which is frequently ornamented with arcadings. The ornamentation is particularly rich in the doorways; the columns are generally round, with square capitals, and very massive and heavy, as though they were intended to support a heavy vault. Most of the Norman English cathedrals have undergone numerous modifications at later periods, but those of Peterborough, Gloucester, Waltham, Winchester, and Norwich have retained much of their original Romanesque character, though Norwich and Durham have Gothic

vaults, and Peterborough a Gothic west front and retro choir. In London, Romanesque or Norman architecture is best represented by the round portion of the Temple Church, the Keep and St. John's Chapel in the Tower [48], and St. Bartholomew the Great, Smithfield.

In Germany the Rhine provinces hold the finest examples of Romanesque architecture, which is here closely allied with that of Northern Italy. A most impressive feature is offered by the numerous octagonal and circular turrets, and the arcaded galleries with which the churches are adorned. The articulation is very clear and simple, and every member of the building is given just the necessary degree of prominence. Vaulting was first introduced in the Rhenish provinces, but only about half a century after its general adoption in France. Romanesque church buildings abound in almost every part of Germany, and we need only mention the cathedrals of Worms, Speyer, Aix-la-Chapelle, Mayence, Treves, Bonn, and Regensburg.

**Influence of the Church on Art.** Throughout Europe, wherever the Romanesque style took root, the artistic expression of the period was essentially architectural. It was a time of general, as opposed to individual, ideas, and the flourishing of sculpture and painting can only coincide with that liberty of the individual which was then practically non-existent. Then the practice of the fine arts was almost entirely in the hands of the Church, and had to follow strictly traditional lines. The chief object of art in the hands of the priests and monastic orders was edification and instruction, and the means

47. INTERIOR OF PISA CATHEDRAL

Alinari

by which this was achieved was adherence to conventional symbols. The forms of antiquity had lost their natural grace and flow of line in the Byzantine period, and were handed over to the Romanesque craftsmen in this stiff and formal modification. A considerable stretch of time was needed before the Northern races could rediscover the classic spirit that lay concealed under this formalism, and before they could develop a new style upon this foundation. In subject matter, as in form, the ruling of the Church dominated Romanesque art, and secular subjects occur but on rare occasions, as in the famous Bayeux tapestry, in which William the Conqueror's wife gave a naive pictorial record of the conquest of England by the Normans [49]. But Christian symbolism in art was by no means confined to scriptural representations, and, as we have already found in the paintings of the catacombs, the characters of ancient mythology were frequently repeated, though a new symbolical meaning was now attached to them. A solemn, dignified formalism prevails throughout, which favours the typical rather than the individual.

**Plastic Art.** In plastic art, the Romanesque period is chiefly remarkable for the numerous beautifully executed ivory carvings, which have been preserved in considerable numbers, and constitute the most complete link

that connects the classic with the Gothic period. The craftsmen of that era also excelled in bronze casting, and numerous church doors with figure reliefs still testify to their skill. The art of enamelling was extensively practised, particularly at Limoges, and constitutes, through its application to metal work in relief, a transition from painting to sculpture. The method employed by the Limoges workers (*champlevé*) differs from that of the Byzantines (*cloisonné*), in so far as the latter filled the enamels into

48. ST. JOHN'S CHAPEL, TOWER OF LONDON

compartments formed by gold wire soldered to the base, while the former hollowed out the ground so that the gold or gilt outlines, which divided the different colours, stood out in relief. Painting was entirely confined to the illumination of manuscripts and the decoration of church walls with conventionally treated figures.

The striving for artistic freedom and new forms is clearly perceptible in the closing epoch of the Romanesque period, though for a long time it was kept down by the severity of the hierarchic tradition and by the rule of the Church, which practically dominated every manifestation of the artistic spirit. Only about the beginning of the thirteenth century, with the dawn of the Gothic epoch, did art attain to that individual expression which makes it a vital factor in the life of nations.

FARMING

continued from page 3206

By Professor JAMES LONG

## WESTERN AUSTRALIA

The great colony of Western Australia occupies the entire western portion of the continent. It contains some 625,000,000 acres, being, therefore, twelve times as large as England and Wales. It is divided into six portions, Kimberley in the north, a country highly suitable for stock rearing; the North-west and Westerly Divisions, with their rich pastoral plains, which render them specially adapted for the production of meat; the Eastern Division, which forms the centre of the province; the South-west Division, containing a large area of good soil, adapting it to the production of grain, vegetable, and fruit crops, and therefore to agricultural settlement; and Eucla, a portion of which contains splendid pasturage, but which, in the main, is badly watered. It is in the south-west, however, where settlers are taking up land, and where the chief portion of the population—which has increased from 137,000 to 255,000 in ten years—mainly resides. During the past eight years the area of land under crops has increased from 111,000 to 327,000 acres.

**A Promising Outlook.** Western Australia, with its huge area, varied soil, rich pasturage, and salubrious climate, much as the temperature and rainfall vary, affords wonderful opportunities to the farmer, the stock-breeder, the dairyman, and the fruit grower. There are free grants of land and loans of money by the Government, while the prices obtainable for most kinds of produce are exceptionally good, owing to the fact that the demand, which is daily increasing, is greater than the supply. For example, wheat and wheat offals, oats, barley, potatoes, bacon and hams, butter, cheese, preserved milk, eggs, frozen meat, cattle, and sheep are all imported, for the reason that production is not equal to the consumption, and these form only a portion of the food stuffs which are imported for the use of West Australian people. The outlook for the future of the colony is therefore most promising, for having overtaken its own consumption, it will be in a position to supply other countries with unlimited supplies.

The first winter rain follows the close of summer in April. The rainfall, which is greatest between May and September, averages 33 in. at Perth, reaching 40 in. on the coast further south. At Kimberley, to the extreme north, it varies from 20 in. to 27 in., falling to 20 in. in Eucla, and 9 in. in Coolgardie. The chief agricultural industries are the production of milk and milk products, grain, meat, fruit and vegetables.

In the ten years ending 1903, 7,500,000 bushels of wheat, averaging 11 bushels to the acre,

were produced. The quantities of grain grown in the season 1904-5 were as follow:

|              |                   |
|--------------|-------------------|
| Wheat .. ..  | 2,013,000 bushels |
| Barley .. .. | 37,000 ..         |
| Oats .. ..   | 226,000 ..        |

**Wines and Wool.** In 1903 West Australia produced 137,000 gals. of wine, and 13,000,000 lb. of wool, which represents an industry that can be almost indefinitely extended. The wheat grown is of high quality, and in some districts reaches 65 lb. per bushel, the wheat belt being one of the finest in the world, and failure of a crop almost unknown. In the most suitable districts for dairying, the establishment of butter factories and creameries will ultimately be on a large scale, for Nature has provided unlimited provision for the feeding of stock and the production of milk. Both climate and soil, in districts adapted to the purpose, favour the fruit-growing industry, and to such an extent that not only is it possible to produce European varieties but also those which are common to semi-tropical climates, and which are adapted, like the grape and the currant, to drying or converting into wine. It is officially stated that the vine may be grown along the coastline for a considerable distance, and as far as 150 miles inland without artificial provision of water.

West Australia is liberally endowed by Nature with timber of many valuable kinds, the chief varieties being estimated to cover 20,000,000 acres, of which 8,000,000 acres are jarrah. Timber leases and licences are granted upon advantageous conditions.

**Purchase of Land.** The landlords of the colony are especially generous to the settler, conditionally upon his clearing and cropping 40 acres, fencing, and erecting a house to the value of £30; while a free homestead farm of 160 acres is supplied for a single sovereign, but the settler must reside on the land for six months in each of the first five years. Apart from this, land from 100 to 1,000 acres in area can be obtained at 10s. an acre, payable in half-yearly instalments, at the rate of 3d. per acre for 20 years; improvements must be effected to the value of 10s. per acre with residence, or 20s. without, and within ten years a boundary fence must be put up to the extent of one-tenth within two years, and completed within five years. Fruit growers, gardeners and others can obtain small areas of 5 to 50 acres of land at £1 per acre, but they must erect a fence within three years.

Pastoral lands are leased under various conditions; in Eucla, for example, blocks of 20,000 acres are leased at 5s. per 1,000 acres per annum; in the eastern division similar blocks are charged 2s. 6d. per 1,000 acres for each of the first 7 years.

## AGRICULTURE

and 5s. for the remaining years' lease. In Kimberley, in the north, blocks of 1,000 acres with frontage or 20,000 acres without a frontage are let at 20s. per 1,000 acres per annum. In the south-west the rentals are high; blocks of 3,000 acres—the area being curtailed—are charged £1 per 1,000 acres, or 10s. in the less advantageous districts.

**Concessions to Settlers.** The settler is met by Government with various concessions; he is taken to the land where he desires to make a selection, free of charge; on paying his fees and having made his selection, he and his family, with his goods, receive a special concession from the Railway Department, the fares being debited against him for repayment by bills at 24 months at 5 per cent. interest. He can, too, obtain advances under the Agricultural Banks Acts to enable him to make his improvements and carry on his work, but there must be no mortgage or other encumbrances on the land. He can pay half his liabilities, carry on his farming, grazing, or other work on the land, or add to his improvements by the aid of an advance, but such advance must not exceed two-thirds of the value of the land, and the improvements which have been made, nor must they exceed £1,000. In the case of improvements, the advance refers to the clearing, cultivating, ploughing, and fencing of land, draining, well-sinking, and building, and, indeed, any form of improvement which will increase the capabilities of the land. Where loans are thus contracted, they are repayable within 30 years under the principal Act, but the borrower is required to pay interest only during the first five years, after which he commences to repay the principal.

Passages to West Australia are offered to approved emigrants owning not less than £100 at £7 per adult and upwards, or £13 where the emigrant has no capital. The settler has little to pay on his arrival; there is neither income tax, land tax, tithe, nor poor rate, while his sons, desiring to occupy land, can be trained at either of the two Government experimental farms at 10s. 6d. per quarter, including maintenance and instruction.

## SOUTH AUSTRALIA

South Australia, which covers over 900,000 square miles, one-third of the whole continent, possesses a population of 373,000, excluding 43,000 Maoris. In the northern territory, which is the larger portion of the province, covering over 500,000 square miles, there are only 4,000 people.

**Climate.** The climate of South Australia varies, but it is claimed that in the temperate district of the south, like Victoria and New South Wales, it closely resembles the climate of Italy, although in the north the heat is considerable, owing to the existence of practically tropical conditions. The hot months are from December to February, these being followed by November and March, when, however, the nights are cooler, while summer extends from October to March, after which the temperature falls. The weather during winter, April to

October, especially in its two first months, is regarded as perfect.

**Products.** In 1904, the area under tillage was 3,316,000 acres, the Crown land alienated during the same year reaching 388,000 acres. The chief crops, with the area on which they were cultivated, and the quantity grown, are shown in the following table:

| Crops.                      | Acres.    | Quantities.         |
|-----------------------------|-----------|---------------------|
|                             |           | Bushels.            |
| Wheat .. ..                 | 1,840,157 | 12,023,172          |
| Oats .. ..                  | 50,630    | 555,696             |
| Barley .. ..                | 23,904    | 346,718             |
|                             |           | Tons.               |
| Potatoes .. ..              | 8,315     | 19,521              |
| Hay .. ..                   | 269,626   | 204,252             |
|                             |           | Gals. of wine made. |
| Vines .. ..                 | 23,210    | 2,625,430           |
| Green Forage .. ..          | 45,274    | —                   |
| <i>Miscellaneous Crops:</i> |           |                     |
| Almond Trees .. ..          | 187,321   | 7,527 cwt.          |
| Apple .. ..                 | 688,031   | 362,436 cwt.        |
| Lemon .. ..                 | 69,610    | 37,720 ..           |
| Orange .. ..                | 151,593   | 103,893 ..          |
|                             |           | Produce.            |
| Olives .. ..                | 83,138    | 15,980 gals. oil.   |
| Raisins .. ..               | —         | 8,697 cwt.          |
| Currants .. ..              | —         | 16,714 ..           |
| Garden & Orchards .. ..     | 29,032    | —                   |
| Honey Hives .. ..           | 23,633    | 1,197,737 lb.       |

Wheat is easily the principal grain crop, but in the same year over 1,000,000 acres were under fallow. It will be noticed that South Australia produces the orange, the lemon, the almond, and the olive; while apples form an important product, other fruits such as raisins and currants being capable of growth upon a vastly extended scale.

The quantity of wheat grown per acre in 1904-5 was just under 7 bushels, while oats reached 11 bushels, barley 14½ bushels, potatoes 2½ tons, and hay 1 ton per acre.

**Livestock.** The table which follows will enable the reader to obtain some idea of the stock-breeding capacity of the province; the number of animals referring to the year 1904. There were in all:

|           |           |           |         |
|-----------|-----------|-----------|---------|
| Horses .. | 200,241   | Cattle .. | 520,379 |
| Sheep ..  | 5,874,979 | Pigs ..   | 112,584 |

**Land Tenure.** Of the 243,000,000 acres in South Australia proper, 93,000,000 are in occupation, 8,000,000 having been alienated, and 85,000,000 acres are held under Crown leases, thus leaving 150,000,000 acres for settlement. Land is sold by the State under the deferred payment system, the receipts forming about 7 per cent. of the total revenue. There are in all 77,000,000 acres of land held by Crown lessees as sheep and cattle runs. Near the larger centres of population, small plots of land are obtainable on lease by working men, up to 20 acres in extent, but personal residence is required. Leases with right of purchase, exercisable after six years, are allotted for terms of 21 years, with rights of renewal, while land let on perpetual leases is re-valued every 14 years. On the basis of freeholds, and of

Government leaseholds jointly, the average area of land occupied, equals 70 acres per head of the population, excluding pasture land.

**Wine, Butter, and Cheese.** The production of wine is largely increasing; in 1892 there were 8,750,000 vines, of which only 4,000,000 were bearing; ten years later there were nearly 12,000,000, the wine produced reaching nearly 2,250,000 gallons. In the same year the quantity of butter produced was over 4,500,000 lb., and of cheese 700,000 lb.

"The favourable conditions which exist, with the small cost of cultivation," says Mr. Coghlan, one of the highest authorities in Australia, "makes a yield of 7 bushels of grain in South Australia as satisfactory as 15 bushels in New South Wales, or 20 bushels in New Zealand." The mechanical operations of a 1,000-acre farm cost, according to one authority, the farmer himself 4s. 11½d. per acre; while in another case the cost is placed by the grower at 1s. 1½d. per bushel of grain. Details, however, on this point, and in relation to the cultivation of the various crops of the province, of irrigation, of fruit-growing, dairying, and the wine industry, may be found in the work issued by the Government, entitled "The Central State: Its Progress and Resources." We may, however, point out, in regard to the dairy industry, which is advancing in all parts of Australia, that the quantity of butter produced varies from 4,500,000 lb. to 5,500,000 lb. per annum; and of cheese, from 700,000 lb. to 1,000,000 lb.; and, further, that there is a great opening in the more temperate districts for a large extension of this particular work. The butter and cheese factories already in operation number 68.

**Wool.** As in other parts of Australia, the wool industry is one of great importance. Although not so numerous as between 1875 and 1890, there are nearly 6,000,000 sheep in the colony, the wool exported in 1902 reaching £1,125,000 sterling in value. The following figures show the actual weight of the fleece per sheep at different periods, and in different provinces, South Australia taking the best place:

| State.             | 1861. | 1871. | 1881. | 1891. | 1901. |
|--------------------|-------|-------|-------|-------|-------|
|                    | lb.   | lb.   | lb.   | lb.   | lb.   |
| South Australia .. | 4·69  | 6·41  | 6·93  | 6·85  | 7·9   |
| New South Wales .. | 3·28  | 4·57  | 4·47  | 5·74  | 7·2   |
| Victoria ..        | 4·52  | 6·17  | 6·87  | 5·68  | 6·9   |
| Queensland ..      | 3·40  | 4·73  | 4·50  | 4·73  | 7·1   |
| New Zealand ..     | 3·48  | 4·76  | 5·32  | 6·42  | 8·1   |

The fact that so large a portion of South Australia is tropical is sufficient to indicate its wonderful capacity—especially in the river valleys—for the production of tropical fruits, cotton, tobacco, sugar-cane and other semi-tropical crops.

### QUEENSLAND

Queensland embraces 428,000,000 of acres, or twelve times the area of England and Wales, The estimated population at the end of 1904 was 521,000, three-quarters of whom dwell in houses which are timber-built, owing to their coolness and cheapness. The climate is varied, like the

rainfall. The only district within the temperate zone is known as Darling Downs, where the temperature is delightful, owing in part to its elevation. The winter extends from May to July inclusive, and the summer from December to February, during which most of the rain falls. The summer is hot but not sufficiently so to prevent work out of doors. The rainfall varies from 10 in. in the western districts to 77 in. at Mackay. Brisbane averages 51 in., while in the south part of Cook 160 in. have been registered in a year. Apart from minerals, the chief products of Queensland are wool, maize, wheat, sugar cane, livestock, timber, and butter. The chief industries, therefore, are pastoral and agricultural, the grazing farms in particular being of considerable size.

**Extent of Crops.** Owing to the heat, the number of livestock varies, like the yield of grain crops, from year to year, large numbers of cattle and sheep dying during severe droughts; for a similar reason the wool crop, and the production of frozen meat vary in quantity. In 1904 the quantity of wool exported was only 47,000,000 lb., but although this was 12,000,000 lb. more than in 1903, it was much less than in many previous years. The value of the wool exported in 1904 exceeded £2,250,000 sterling, and of livestock nearly £1,500,000, while preserved meats, including both salted and frozen, reached £700,000, or less than half the value of the exports in 1902, and butter £290,000, an enormous increase on previous years. The value of the sugar export reached £1,250,000 sterling in the same year. The following figures show the extent of leading crops during the three years ending 1904:

| Year. | Land in Cultivation. | Wheat.  | Barley. | Maize.  | Sugar-cane. | Lucerne and other Green Forage. |
|-------|----------------------|---------|---------|---------|-------------|---------------------------------|
| 1902  | 478,121              | 1,880   | 430     | 89,923  | 85,338      | 51,279                          |
| 1903  | 621,693              | 138,096 | 22,881  | 133,090 | 111,516     | 26,576                          |
| 1904  | 577,896              | 150,958 | 17,387  | 119,171 | 120,317     | 35,861                          |

Maize averages from 16 to 31 bushels per acre in the south, and from 35 to 43 bushels in the north of Queensland. From 1895 to 1904, one great failure excepted, the wheat crop varied from 9½ to 19½ bushels per acre. Among other crops are barley, which in 1904 yielded 19 bushels for malting; oats, which produced 24 bushels; lucerne, which yielded 1½ tons of hay, potatoes, millet, rice, tobacco, cotton, coffee, and various fruits, including the grape, bananas, oranges, lemons, mangoes, pineapples, limes, and coconuts.

The following table shows the number of animals owned in Queensland during two recent years:

| Animals.               | 1903.     | 1904.      |
|------------------------|-----------|------------|
| Horses .. . . .        | 401,964   | 413,165    |
| Horned Cattle .. . . . | 2,481,717 | 2,792,340  |
| Sheep .. . . .         | 8,382,044 | 10,143,470 |
| Pigs .. . . .          | 117,553   | 185,141    |

## AGRICULTURE

It is officially stated that some two-thirds of the owners of sheep own less than 1,000 sheep each, while about 150 own over 20,000 each. Farmers owning cattle are much more numerous, but in most cases the number of animals owned does not reach 100.

Dairy farming is gradually developing, and factories for the production of butter and cheese are increasing in number. The production of poultry, and the curing of bacon and hams, are industries which are also making way. In the year 1904 nearly 8,000,000 lb. of butter were exported to England and other countries. Useful dairy cows are obtainable at from £7 to £12 each.

**Purchase of Land.** The cost of unimproved and improved land suitable for farming and dairying varies from £1 to £4 per acre, while orchard land in the best localities, near railways and roads, realises as much as £20 an acre. Farmers are able to obtain advances under the Agricultural Banks Act for the purposes of meeting liabilities already existing on the holding; for agricultural, dairying, grazing, and horticultural pursuits on the holding; for making additional improvements to those already in existence; and for the purchase of stock, machinery, and other farm appliances. The money must be repaid, by half-yearly instalments of £3 11s. per £100, including interest, within 25 years. There is an excellent Agricultural College for students between the ages of 14 and 21 years; the charges for the year are £27, including board, lodging, and laundry. The cost of living as compared with the wages paid is low.

Agricultural land is obtainable under a system of deferred purchase on a term of 21 years. The tenant first obtains a licence to occupy, and, later, a lease, and the lease ultimately merges into a deed of grant on completion of the purchase. Under the licence and lease, an annual payment is necessary as a survey fee, which is divided into five equal instalments, and an annual rent equivalent to the fortieth of the purchase price. The sums paid as rent become instalments in part payment of the purchase, so that when the lease has expired, half of the purchase price will have been paid, another year being allowed for the payment of the remaining half; if payments are punctually made, no interest is charged.

**Gradual Payments.** A farmer in Great Britain having deposited the year's rent and one-fifth of the survey fee, is entitled to receive a certificate of title to the land, and he has six months given him in which to present this certificate to the District Commissioner in Queensland. He then receives his licence to occupy, and, if he choose, can obtain a further six months before he enters into occupation. Subsequently, and until he obtains his freehold, he must continuously occupy the land, which must be enclosed, with a substantial fence within five years; or, on the other hand, he must make such improvements as will be equal in value to such a fence. The Government gives him a reduction of 5 per cent. on the usual freight

rates for all fencing and building material for use on his farm. When the improvements have been completed, he is entitled to his lease, and is then in a position, if he so desire, to mortgage the land, or, by permission, to subdivide or transfer it, or, as the case may be, to underlet it. Where purchase is completed by earlier payment, a discount of 2½ per cent. is allowed.

**An Easy Road to Success.** A person selecting land as we have described, and who pays his own passage money and that of his family, is entitled to be credited with such sums towards the payment of his holding, not exceeding £17 per adult, and he is not required to pay any further instalment of land or survey fee until such time as these payments have been covered. Farms now offered are situated in a mild climate, within easy distance of railways, and in districts in which the rainfall is adequate. Sir F. Tozer says that with a capital of £100 a man should be able to manage. By combining dairy work with other forms of culture, the achievement of success has been made easier than was formerly the case. The price of agricultural farms is not less than 10s. an acre, but as much as 1,280 acres can be selected by one person. Of farms other than agricultural farms, ten years' residence is necessary to obtain the freehold. In the year 1904, 136,000 acres of land were sold for agricultural farms at an average price of 16s. 10d. per acre, but land not exceeding the limit may also be bought without conditions at an upset price of 13s. 8d., or rented at 5 per cent. of the purchase price.

In the case of homesteads not exceeding 640 acres, special facilities are given for acquiring the freehold; the settler must pay 3d. per acre per annum, and 2s. 6d. to 10s. per acre in improvements, when, having resided on the land or near it for five years, and finally paid a sum which, with the rent already paid, makes up 2s. 6d. an acre, he is entitled to the freehold.

**Grazing and Dairy Farms.** Grazing farms up to 20,000 acres in area are obtainable at an annual rent of ¼d. per acre for the first seven years, but the land must be fenced within three years instead of five. Leases are granted for periods of 14, 21, and 28 years, but they may be extended on a re-assessed rent. In 1904 the average rent of such a farm was 1½d. per acre.

Where a farmer resides on a grazing homestead intended for dairy farming for five years, such land may be obtained up to 20,000 acres in extent; here the minimum rent is also ¼d. per acre, but the average rent paid in 1904 was 1½d. per acre.

## NEW SOUTH WALES

This colony covers 198,000,000 acres. Its population, which has increased by nearly a quarter of a million in 10 years, numbers about 1,500,000.

**Climate.** The country possesses several ranges of high mountains, adding both to the beauty of the scenery and the diversity of the climate—for while snow clothes their summits in winter, it is practically unknown in Sydney, the capital of the state. The temperature varies

from the lowest winter experiences of England to the warmth of southern Europe. There are dry seasons, as elsewhere, which appear at intervals, but the rainfall is usually sufficient owing to the precautions which are taken in the construction of reservoirs and wells, although the average is low in many parts of the colony. The heaviest average is on and near the coastline, where it varies from 74 in. in the north, to 29 in. in the south; while the lowest fall is in the extreme west, where it varies from 7½ in. in the north to 11½ in. in the south. In a word, the mean number of inches increases as we progress from the extreme west to the coastline in the extreme east, and, again, the rate of progression, if not quite so marked, proceeds in a similar manner from north to south.

**Forests.** The forests of New South Wales are numerous and large, no less than 6,250,000 acres being reserved, while timber growing on prodigious areas may be worked under a system of licence and the payment of a royalty. The woods are of many varieties, and are as remarkable for their beauty as for their durability and suitability for ornamental and utilitarian purposes. Of flowering plants and ferns there are 3,500 species of the 9,000 known to the Australian continent. Of the 1,600 examined by the director of the Botanic Gardens 630 were timbers, and 460 suitable for human food and forage.

The soil of the colony is in many parts remarkable for its high quality, especially in the lower lands near the coast. Red loam is prominent in the slopes of the vast interior and the west, rendering the country peculiarly well adapted to the purposes of the farmer. There are, too, vast plains of loam in the grass and saltbush districts, and, although liable to drought, the fertile character of the land is such that a fall of rain is rapidly succeeded by the growth of herbage.

In the pastoral districts, which are numerous and large, and extensively covered by saltbush, millions of sheep and cattle are fed with profit. In the purely agricultural districts the farmer grows the cereals, hay, vegetables, fruits, and sugar, while in some cases the climate and soil are pronounced to be suitable for cotton, the vine, tea, and coffee. In the central tablelands are 12,000,000 acres, and in New England there are 16,000,000 acres suitable for cereals, hay, and English fruits, while on the vast slopes of the dividing range there is an expanse of country, from 100 to 150 miles in breadth and covering 40,000,000 acres, adapted to wheat and the vine. Other districts, embracing millions of acres in each case, are suitable for the production of maize and the vine.

**Area Under Crops.** In the year 1906 the land on which crops were cultivated extended to 2,838,000 acres—wheat accounting for 1,938,000 acres and hay for 438,000 acres. Wheat returned 10½ bushels per acre, oats 22½ bushels, maize 30 bushels, and hay 1 ton. The area under maize was 190,000 acres. Sugar-cane covered 9,500 acres, and vines for wine 5,300 acres. The quantity of wine produced in 1905 was 928,000 gallons,

against 1,086,000 gallons in 1904; but in 1906 the area on which the vine was grown was largely in excess of either of these years. The yield of wine per acre varies with the season, but in the past 10 years it has never been lower than 160 gallons, and has reached 213 gallons. Sugar-cane reaches 20 tons to the acre.

In the direction of livestock the colony possessed the following numbers in 1905:

|                    |            |
|--------------------|------------|
| Horses .. ..       | 506,000    |
| Dairy cows .. ..   | 614,000    |
| Other cattle .. .. | 1,693,000  |
| Sheep .. ..        | 39,494,000 |
| Swine .. ..        | 310,000    |

Sheep show an enormous increase (5,000,000) over 1904, and dairy cows over 50,000. The dairy industry is rapidly progressing, as the following figures show:

| Year.      | Production. |           |
|------------|-------------|-----------|
|            | Butter.     | Cheese.   |
|            | lb.         | lb.       |
| 1895 .. .. | 23,295,000  | 2,938,000 |
| 1900 .. .. | 41,479,000  | 3,558,000 |
| 1904 .. .. | 53,591,000  | 4,223,000 |

Dairy goods are chiefly produced in factories in districts near the coast. The milk is sold by the farmers at definite prices, but in most cases the work is conducted on the co-operative plan, so that the producer shares in the profits. Winter feeding of the stock is much less difficult and costly than in England, while the prices realised in London compare advantageously with those realised by English producers. Thus, in 1905 top prices for New South Wales butter varied from 95s. per cwt. in May to 115s. in December, the lowest prices being 87s. in spring. In Sydney the best brands of butter varied from 9½d. to 11½d. per lb. wholesale, and of cheese from 5½d. to 7½d. Eggs in the same year ranged from 6½d. to 16½d. per doz., and bacon by the side 5½d. to 7½d. per lb.

**Wool.** One of the chief articles of New South Wales produce is wool, of which 249,000,000 lb. were produced in 1904, or nearly 100,000,000 lb. less than in 1895. The average prices realised in London varied from 10d. to 12½d. per lb. in the grease, and from 1s. 6d. to 1s. 10d. when scoured.

It is a fact worthy of consideration by those intending to emigrate, that large numbers of livestock, fruits, vegetables, sugar; and wool are imported, thus suggesting that there is an opening for production in these directions. The breeding of first-class cattle and horses, and the production of milk for the manufacture of fine butter and cheese, all practically ensure a good return, and we may take it that the accomplished cheese-maker starting in this, as in either of the other Australian colonies, in a dairying district, may realise for sale to the consumer direct a larger sum than can possibly be obtained where similar goods are produced in factories for export. An intending settler interested in dairy work and making himself thoroughly acquainted with the manufacture of fine Cheddar, Cheshire, Stilton, and one or two varieties of high class soft cheese, is always in a position to command a more or less lucrative market.

## VICTORIA

Victoria, which possesses an estimated population of about 1,250,000, covers an area of 56,000,000 acres, being slightly smaller than Great Britain. Its climate is somewhat similar to that of Italy and the South of France. Mountain ranges form about one-fifth of the whole area, the remainder consists of more or less flat alluvial soil. The country is well timbered, although a large area of forest land has been cleared, and is now under cultivation, natural grasses being produced, and employed in the fattening of cattle and sheep without the addition of food of any other kind.

**Climate.** The average rainfall, as recorded at Melbourne for 46 years, was 25·6 in., while the average number of days during which rain fell yearly was 132. The seasons are mild to warm, ranging from an average temperature of 49° F. in winter to 65° F. in summer, so that farm work can be conducted at practically all times. The thermometer seldom reaches 100° F. in the shade; but owing to the dryness of the heat, this temperature is not more perceptible than 80° F. in many other countries. For these reasons the stock of the farm is left in the fields at all seasons, fattening for the market with considerable ease. Where the rainfall is slight, irrigation and the conservation of water have been, in part, provided, but are being pushed forward by the Government, so that large areas speedily respond to the work of the farmer.

The variety of crops grown is enormous on the better class of soils. In the north country, maize, lucerne, roots, sorghum—a sub-tropical forage plant somewhat resembling maize—green rape, linseed, and the grasses all flourish, while sugar-beet and tobacco are gradually extending, and under skilled cultivation, promise to become large industries in the near future. The fruits known in Great Britain grow with great success, while the apple is exported in large quantities; oranges, grapes, figs, and lemons are also grown to a high state of perfection.

**Products.** Among the chief products of the country, apart from those mentioned, are wool, chiefly obtained from the Merino, the Lincoln, the Leicester, and crosses between these breeds; a variety of tinned meats; many varieties of wine; bottled, canned, dried, and pulped fruits, jam, canned and other vegetables, with butter, condensed milk, and olive oil.

**Exports and Imports.** The value of the dairy produce exported in 1905 reached £1,800,000, the quantity of butter alone being 36,000,000 lb. weight. In the same year, the export of wool reached £5,500,000 sterling in value, mutton and rabbits over £400,000, wheat and flour over £3,000,000 sterling, sheep-skins and leather £650,000. It is estimated by Mulhall that the total production in primary industries reaches £22 15s. per head of the population in Australia, as compared with £7 18s. in the United Kingdom. Food is cheap in comparison with the wages paid.

Agriculture is regarded as the best means of obtaining a livelihood. The most important crops, especially those essential to the feeding

of stock, ensure a good harvest under good cultivation. The grain yield varies with the season and the rainfall. In 1903-4 wheat averaged 14½ bushels to the acre, but fell in the following year to 9½ bushels. The value of the wool exported in 1904 was nearly £5,000,000 sterling. There are in Victoria some 10,000,000 sheep, flocks in some cases reaching from 10,000 to 50,000 head, and the cultivation of special crops such as lucerne and rape is now being rapidly pursued for their more speedy and economical feeding. The production of lamb for export is also becoming an important factor in the agricultural system of the colony. As wool stands first as a staple production, so wheat comes second, this crop being grown upon easily worked loamy soils which are ploughed, not as in England, by the single furrow, but by ploughs which take three and four furrows at a time. The crop is harvested both by binders and strippers, the latter machine taking off the ears of the corn, from which the grain is at once removed, without cutting the straw. On large farms, it is believed that from four to five bushels of grain repays the entire cost of growing the crops per acre.

**Dairy Produce.** Apart from the large export of butter, it is estimated that 10,000 tons are locally consumed, and that the value of the milk consumed, and the cheese made, reaches £785,000. The value of the entire produce of the dairy is placed at nearly £4,000,000 sterling. There are 200 co-operative butter factories in the colony, some of which produce 30 to 40 tons weekly. In the best season, milk is either taken to the factory and there separated—the farmer taking home the skimmed milk—or the milk is separated at home, and the cream taken to the factory. The number of cows is rapidly increasing, there having been an increase of 33 per cent. during the past five years, largely owing to the help given by the Government. Dairy farms realise good prices, and a return of £10 per cow per annum is not uncommon.

**Government Land.** The Government, which purchases large estates for sub-division and sale to farmers upon easy terms, charges less for its land than the buyer is required to pay in the open market. The sums annually payable are regarded as no more than a small rent for a number of years. The land is all within easy reach of railways, and in many cases less than 100 miles from the capital—Melbourne—or some important seaport. The half-yearly payments, including interest, are equal to 3 per cent. of the total value of the allotment, and the purchaser may extend the period of payment over 31½ years. One-fifth of the total value of the allotment must be effected in the form of improvements, but these improvements must be made within six years; one-third by the end of the first year, one-half by the end of the third year, and the balance by the end of the sixth year. The external boundaries must be fenced within three years. Settlers may make payments in advance, and thereby secure a reduction.

# THE USE OF SPECIAL STONES

Steps. Staircases. Templates. Hearth Pavings. Protection  
Against Decay. The Marble Mason. The Slate Mason.

Group 4  
**BUILDING**

23

Continued from  
page 3148

By Professor R. ELSEY SMITH

IN almost every building, even though there be no masonry walling, the mason will have to provide some amount of stonework for special positions, and in many cases to assist other tradesmen in fixing such work. In a very large number of brick-built buildings the sills, and sometimes the heads of the openings, are formed of stone, and also the thresholds and steps of doorways. The various stones resemble, generally, similar stones in a stone building; but it is desirable, where they are to be used with brickwork, that such stones should be of a size to bond readily with the other material. The head alone may be moulded if required, and the moulding stopped against the jamb, or the moulding may be carried round both head and jambs. Sills should always be grooved to receive a water bar when the wood frame is inserted, and should project beyond the face of the wall and have a throat, or groove, on the under side to form a drip. They are not provided with dowels when brick jambs are used. It is not desirable to use sills under 4 in. in thickness, and it is better that they should be not less than 6 in.

**Thresholds and Steps.** These are usually formed of solid stones of the required size, and can, except for very large openings, be obtained, as a rule, in a single stone. They should be built in at least 4½ in. at each end of an opening, and be provided with mortises to receive a dowel fixed in the door frame.

Staircases in stone may be formed of solid stone or built up of slabs forming treads and risers—the latter form is not generally employed except for outside work, and make a cheap form of stair [169]. The treads are usually of hard York stone 2½ in. or 3 in. thick; the risers may be 2 in. Such treads require to rest upon a support at either end, or to be built into a wall at both ends; they may be tooled or rubbed and should be bedded with a slight fall towards the nosing so as not to retain water. The edge, or nosing, of such steps may have a slight chamfer worked on it. In steps of a better class a small bullnose is often worked on the edge when a regular moulded nosing is not employed. In stairs of small width treads alone may be used, and the risers omitted.

**Solid Stone Steps.** Solid stone steps are more satisfactory and more customary, and may be supported by walls or girders at each end, or built into a wall at one or both ends; but steps exceeding about 4 ft. 6 in. in width should be supported or built in at both ends [173]. Solid steps may be rectangular in section, and may be constructed so that the front of one step merely rests on the step below it for a width of

about 2 in.; but such steps when used externally are very liable to let wet through at the joint, and this may drip from the soffit. A better method of jointing is to use a rebated joint, or a rebated and splayed joint [170], which involves, however, the use of deeper stones than in the former case, in which the depth of the stone equals the rise of the step.

**Section of Steps.** Solid steps may also be spandrel-shaped in section. This form is used only where importance is attached to the appearance of the soffit, as it involves additional labour, but with spandrel steps a plain sloping soffit can be secured, and if the steps be uniform in section throughout their length, much labour is saved by sawing them out to the required form [171, and 160, page 3037]; but if the step be built in only at one end, forming what is termed a *hanging step*, it is usual to have a square seating for so much of the step as is built into the wall to facilitate the pinning in, and such steps cannot be sawn as described, as the thickness is not uniform. The bottom step of a flight is, as a rule, rectangular in section, and, unless the flight is enclosed with walls on both sides, has the outer end formed with a bullnose or curtain end [172].

Except in cases in which both ends are built into walls, the outer end must be protected by a railing, which is usually of iron. The top of each tread is generally mortised to receive one or more balusters; they are, however, sometimes let into the vertical outer end of the steps, which is an advantage where the width of the staircase is restricted; in some cases a framed iron balustrade is employed, and may only require a standard and corresponding mortise in every third or fourth step.

Quarter or half landings are very usually employed in stone staircases, and can often be obtained in single stones; but if not, are joggled or dovelled as already described.

**Circular Staircases.** If the space within which the staircase is to be constructed is not rectangular, but circular on plan, the staircase will be formed with steps of which the plan of the tread is not rectangular, but is wider near the outer wall than near the central newel or well-hole—that is to say, all the steps are *winders* [174]. In cases where the diameter of the space enclosed is under 7 ft., a central newel is a necessity, and may be used for very much larger plans. For staircases of small diameter, every step is formed so that the inner end is circular on plan and forms one complete course of the central newel, the riser of the step starting from the face of the newel at a tangent to the curve [174]; the outer end is much broader,

and is built into the enclosing wall. With larger staircases, the central newel itself may have a considerable diameter. A fine example of such a staircase is the celebrated one at the Chateau of Blois, France, which has a richly panelled newel round which a stone handrail winds; the steps are broad, and the soffit of the flight is itself richly panelled and carved [184-5].

In other cases, however, in which the plan is of large size, the central newel is omitted, each step is a hanging step built into the outer wall, and a central circular well-hole is formed. Such a staircase is described as an *open newel staircase*, and is formed of spandrel-shaped steps throughout. Any hanging step, whether the plan be circular or rectangular, should be built into the wall for 4½ in. at the very least, and 9 in. is more satisfactory, especially if the projection of the step is considerable.

**Wall Handrail.** With a wide staircase a wall handrail, as well as an outer one, is desirable, and if the walls be of stone this is sometimes formed in the walling, not as a projection, but flush with the face of the wall. A considerable hollow is worked above the handrail to allow the hand to grasp it.

A circular staircase may be formed with steps either rectangular or spandrel-shaped in section, but the latter is more usual, and a continuous flowing soffit is formed. The under side of such steps is said to be winding, and must be carefully set out as already described for winding surfaces [157, page 3037]. The soffit is not always, however, a flowing surface; in some cases every stone is marked by a slight projection below the stone next it, marking the line of the joint, and this applies equally to stones in the flights of stairs rectangular in plan. In a flowing soffit, a careful adjustment is required wherever a landing occurs, and, if care be not taken, a somewhat unsightly curve may be produced.

In cases in which the end of the steps are built into a wall, which need not be built higher than is necessary for the staircase, the wall may be finished with a simple coping. The wall itself is finished with a raking top conforming to the slope of the staircase, and the coping is placed on this wall, kneelers being used at intervals to render it secure. In handsome staircases, constructed of stone, such a coping may be richly moulded, and may form, in fact, the base of a balustrade, formed of balusters with a capping, or a wrought-iron balustrade may be employed [186 E].

In many cases this coping is quite plain, being formed either with a semicircular cross-section or with two splay to the arrises, and such copings are also often used to finish area walls, and in similar positions.

**Stone Corbels.** Stone corbels are often required of different forms. They may consist merely of slabs of York stone 3 in. or 4 in. thick built into a wall so as to overhang when it is required to support a projecting pier or chimney breast in an upper floor [175], or to form a core for a projecting cement cornice [176]. This form of corbel for chimneys has the advantage that it may be formed entirely in the thickness of the floor, and so be concealed from view.

Corbels are also not infrequently required for carrying plates [177], and if these are visible from below, they are generally given a more or less ornamental outline with the assistance of a moulding or group of mouldings, and possibly carving. Such a corbel must be let into the wall for at least half a brick, and better for a full brick, or even to a greater extent if the corbel be a large one. It should not be placed at the top of the wall, for, to ensure stability, there must be a sufficient mass of brickwork or masonry above the built-in end of the corbel to resist the tendency which the load on the projecting part exerts to over-balance the stone.

**Templates—Engine Beds.** These are formed with slabs of stone placed under a concentrated load such as that produced by the end of a loaded girder [179] or the base of a column or stanchion [183], or of an engine or piece of machinery, so as to distribute its weight over a sufficiently large area of brickwork to ensure that no fracture shall occur. If the end of a girder heavily loaded were laid directly on the brickwork, it might crush the individual bricks on which it rested, and the template is introduced to prevent this. The area of the template is governed, therefore, by the total load to be carried and the load that 1 ft. superficial of brickwork will support. It is further necessary that the template itself should not be overloaded, and the girder or base-plate must bear directly on such an area of the stone as will avoid the safe crushing load of the material of the template from being exceeded. Such templates are usually formed of York stone, which is laminated, and the upper and lower beds are formed with little labour. The edges that are exposed to view are usually tooled, but may be rubbed, and the face of the template may, if required, be finished as a corbel, projecting slightly beyond the wall face. A template is placed under each end of all girders except the small girders in the thickness of a concrete floor, and under the ends of wood girders and the principals of timber roofs.

Templates under the bases of columns and stanchions often require to have perforations formed through them for holding down bolts which pass through both the template and base-plate, and are secured to a large iron plate built into the pier at a lower level. When such perforations are required either for a column as described, or for bolting down machinery, a wooden template or mould, giving the exact position of the bolt-holes required, is prepared by the carpenter, and the stones with their perforations are worked from this.

**Cover Stones.** Cover stones are used where a wall of brick or stone is carried by a girder, whether of timber or iron [178]. The flange of the girder is in many cases narrower than the thickness of the wall, and it would be difficult to bed bricks on the girder with uniformity. Slabs of York stone, equal in width to the thickness of the wall to be carried, are first bedded on the girder, and the wall is then commenced on these slabs. The edges do not show, as a rule, and need not be carefully finished.

The slabs, which are usually 3 in. or 4 in. thick, should be in moderately long lengths. If the girder be a riveted one, the heads of the rivets must be packed up flush in neat cement, to secure a true bed for the stone, which is bedded usually in cement or mortar.

**Covers to Manholes.** Covers to manholes are generally formed of a slab of York stone 3 in. or 4 in. thick, in which a perforation is worked with a rebated edge to receive the iron frame of the manhole cover. The stone is

and are laid and bedded in lias lime or cement mortar, and should have a fall of  $\frac{1}{4}$  in. in 1 ft. if exposed to the weather. Portland and other stones may be used in the same way, and there are several artificial stones on the market which are excellent for paving. Internal basement passages and the floors of some basement rooms may be paved with similar stone, either tooled or rubbed, and on a kitchen a strip of such stones is provided under the range, and sometimes as a border round the

bedded in mortar on the walls of the manhole, and the iron frame is bedded in cement in the rebate.

**Stone Paving.** Stone paving to yards, areas, footpaths, etc., is generally formed of York stone slabs about 2½ in. thick, cut, where required, to fit any special position, and laid in straight parallel courses so as to break joint. The stones are usually required to average not less than 7 ft. superficial in area. They may be laid on a layer of hard broken bricks, well consolidated, or on a bed of concrete,

room. For internal work, the stones are laid flat, without fall.

**Hearths.** Hearths, and in particular back hearths—that is to say, the portion laid under the grate in the recess formed in the brickwork—are frequently formed of York stone. The back hearth [180] is usually 3 in. thick, the front hearth 2 in., but in many cases substitutes are used for the latter, such as tiles or marble slabs where a better appearance is required, or, where cheapness is important, cement. Stone slabs are sometimes built in between small brick piers to form the

shelves in wine cellars, and the stone may be used as it is split with the front edge tooled.

**Granite Paving.** Granite paving comes rather under the department of road making, but is sometimes required for yards and the entrances to them. A kerb is usually required where a footpath is to be formed, and is generally 12 in. by 6 in. in section, and 3 ft. to 4 ft. in length. Aberdeen and Norwegian granite are much used, and are finished with a fine axed face on the exposed sides, and the heading joints are drafted and jointed in cement mortar. The kerb may be laid on edge without a concrete bed, unless the foundation be bad; but if laid flat a bed of concrete is desirable. In road making a small quadrant stone, not less than 18 in. in radius, is used at the angle where the kerbs of two roads meet, but in forming the entrance to yard gates a larger and easier sweep is often desirable. The kerb forms the edging to the footpath, and a guide to the wheel of any heavy vehicles entering the yard. The surface of the entrance itself is usually formed of *setts* of granite or other hard stone. These are small blocks, usually 3 in., 4 in., or 5 in. on face, and about 7 in. deep, and should be of the same size throughout their depth. They are laid in parallel courses in fine gravel on a thick bed of concrete, grouted in cement, and well rammed with a heavy rammer to secure a true and even surface. The channel between the kerb and the carriage road is formed usually of three or four rows of similar setts, similarly laid.

#### **Spurstones.**

Spurstones of granite or other very hard stone are often provided to the piers of gateways where much heavy traffic occurs. They consist of blocks of granite rounded in form and usually tapering slightly towards the upper end, and placed so as to cover the salient angles of the opening. Their object is to protect the softer material of the wall from damage by the hubs or rims of the wheels of any carts entering and leaving; they should be tall enough above the roadway to turn aside the hub of any cart likely to use the entrance, and in some cases should be tall enough to protect the walls from damage by the tail-board of the cart if a sharp turn has to be made immediately on leaving the yard.

**Hook Stones.** Yard gates, whether of wood or iron, are generally hung to piers of brick or masonry by means of large iron hinges

working on an iron pin or pivot. These pins project upwards from an iron bar of which the inner end is usually split, bent outwards, made rough in forging, and let into the upper surface of a stone block termed a *hook stone*, and run with lead or cement. The stone, with the hook inserted in it, is built into the gate pier.

**Decay of Stone.** The usual causes of decay in stone have been already referred to, and with the softer stones decay sometimes begins to set in within a comparatively short time of their employment. In any position in which it may be foreseen that stonework will be exposed to such influences as are likely to destroy it quickly, it is desirable to select a stone suited to resist these influences to the utmost. If the expense of such a stone be

so great as to be prohibitive, it is best to abandon the use of stone rather than employ a material which is badly adapted to its purpose, and which will in a few years begin to perish. The directions already given as to bedding the stones should be carefully attended to; but with every possible care decay is apt to set in sooner or later. When it begins, as a rule, it first attacks the surface, and works by degrees further and further into the stone unless the process be arrested. This is a troublesome and usually a difficult matter. There are various patent solutions on the market for which the makers claim good results. Recently, at Westminster Abbey,

stonework under cover,

which had seriously decayed as the result of the attacks of an acid-laden atmosphere, has been hardened by the application of a solution of carbonate of barium, under the advice and superintendence of Professor A. H. Church; but several applications of the solution have been necessary, and the process cannot be so well applied to exposed surfaces. Moreover, the solution is poisonous, and special precautions must be taken to guard the health of any workmen employed on this process. Ceresine, a refined wax, has been applied either by means of an electrically heated sprayer, or dissolved in spirits and used like an ointment, and after 24 hours melted into the pores of the stone by a heater. This fills the pores of the stones and prevents the penetration of wet, and is reported on as being found permanently efficient in arresting decay in masonry.

184. TERMINATION OF NEWEL, CHATEAU OF BLOIS, FRANCE

**Protection of Masonry.** Masonry, like brickwork, must be protected during construction from the effects of frost; and, further, as the work is often delicate in character, it requires protection from accidental injury. It is usual to case up all salient angles and projecting mouldings with wood casing after fixing, the cases being left in position till the cleaning down takes place. If the casings are nailed into the masonry joints, damage may be done, and, at any rate, rust stains produced; and where single boards are used for casing, an excellent method of fixing them is to build into the joint above the stone to be protected a strip of stout zinc, and the outer end may be turned down and nailed to the back of the board. If such strips be inserted every few feet they afford good fixing, and when the work is cleaned down the projecting end may be cut off.

Steps and staircases may be cased up in wood, but may also be efficiently protected by bedding hard tiles upon the treads in line. The tiles are removed and the surface cleaned down upon completion.

### Marble.

Marble is a variety of limestone consisting of pure carbonate of lime. It has an exceedingly fine texture, and can be brought to a very fine face and polished. The material varies greatly in appearance; it may be of the purest white, such as that quarried from Mount Pentelicus, near Athens, from which the famous Greek buildings on the Athenian Acropolis were constructed; blocks of immense size were in many cases quarried for the purpose.

**Veined Marbles.** Other marbles are coloured and often richly veined, and show a great variety of tints. They do not all weather well, but for internal use many of the marbles are extremely suitable, and were used by the Romans and Byzantines for internal decorative effect with great success. Slabs of marble of richest colouring were arranged in panels and as rails and styles enclosing panels, the colours contrasted and relieved by bands, sometimes quite narrow, of white or nearly white marble [186 A & F].

Marble is rarely employed as a building material. It is one of the stones that, apart from the labour of working, has an intrinsic value from its rarity, and, except in the neighbourhood of quarries, it is not usual to use it in thick blocks for actual constructive work in walls,

though this is occasionally done. It is not infrequently employed for columns carrying loads, including both caps and bases, though these are sometimes executed in bronze. The Greeks, when they built in marble, used no mortar bed between successive courses, but the stones were worked very true to a fine face, and in many cases rubbed one upon the other to ensure a perfectly true and even bearing; this was particularly the case with columns built up of a succession of drums of stone one above another. The bedding joints were thus truly worked, if not over the entire surface, over the greater part of it, but in the heading joints, which do not take a direct load, the joint was finely worked all round the edge of the stone for a certain thickness, and the centre of the joint was worked somewhat hollow to save the labour of finishing the whole surface.

The stones in successive courses were held together by metal cramps, usually of bronze, sunk

185. CENTRAL NEWEL AND SOFFIT OF GREAT STAIRCASE, CHATEAU OF BLOIS, FRANCE

into the stones in the case of columns of slender proportion, and built up of a succession of drums; bronze dowels were often employed. This system of construction is admirable, but very lavish in the employment of labour, and when marble is employed structurally in modern work a fine bed of powdered stone-dust and lime is very generally used for setting. Portland cement

should never be used for any work connected with marble whether used structurally or merely decoratively, as it will stain the marble, and if marble be used as a facing to walls built in cement, the back of the marble slabs should be protected with a slurry of stone-dust and lime, as already described for limestone. Marbles when used externally are often brought to a fine face, but not always polished, as the polish sometimes does not stand well. Most internal work is polished, as this brings out the natural colours of the marble, and increases the effect and contrasts.

**Preparing Marble.** Marble is usually supplied in large blocks. It is sawn up into slabs of the required thickness by a frame saw similar to that already described for freestones. Marble is afterwards rubbed with coarse and then with fine sand, and for some purposes is left with a sanded face. It may subsequently be rubbed with hone slates and polished by hand or by machinery. Carved work is finished with glass-

paper. The grounding of the best work is effected with fine emeries, and the polishing with putty powder.

**Enriching Marble Surfaces.** When marble is employed, it is important to remember that splendid effects of light and shade are to be obtained without the necessity of deeply sunk mouldings or deep undercutting. Mouldings of comparatively slight projections, if the contours be well arranged, will cast a fine, well-defined shadow, and will be effective in a marble that is nearly or quite white. Where marbles of a veined or mottled surface are used, they are usually best left unbroken by flutes or channels, which, in such examples, often fail to improve the surface appearance but tend to confuse it. A very beautiful effect is obtained when it is intended to use carved enrichment for panels, friezes, etc., by leaving the background of the carving finely tooled and polishing the carved surface [136C].

**Marble as Wall Lining.** Marble forms a beautiful and cleanly wall lining. As already pointed out, it may be used in panels framed with strips of marble of another colour, and both the panels and the enclosing strips may, if desired, be richly veined marbles. A very beautiful effect may be produced by selecting for a panel a small block of marble well coloured and richly veined; thin slabs about  $\frac{3}{4}$  in. thick are cut from this, and by reversing the alternate slabs so that the surfaces are displayed side by side like the open pages of a book, the veins produce an approximately but not severely symmetrical figure [133A]; four such slabs may be cut from a block of suitable size and arranged round a central point in the panel with good effect. In such a position as a dado, the slabs may be reversed alternately and a wavelike effect will be produced, as in the well-known example from the apse of the Basilica at Torcello [136B]. Such wall slabs may be fixed in plaster of Paris, and are further secured by copper cramps let into the edge of the slab and pinned into the wall. The first cost of such a lining is high, but the effect is rich, and the wall finish is a permanent one.

**Hospital Work.** Marble is selected frequently for lining the walls of operating theatres in modern hospitals, partly owing to the cleanliness of the surface and the small lodgment it offers to disease germs, and also to the fact that many kinds of marble can be had in very large slabs, so that there will be very few joints on the surface. Such a lining is not selected primarily for its beauty, but for its utility, and for such purposes no mouldings are worked, the surface being as far as possible unbroken. In some hospitals even the doors of such theatres are formed of slabs of marble supported by heavy gun-metal hinges from a marble frame or lining.

**Marble Floors.** Marble has been used for floors since Roman times, and makes a very beautiful floor, and one that stands wear well. The marble may be used in the form of slabs or tiles of uniform size, and of one colour; or two or more colours may be used, and the tiles

varied in form and size to produce a geometrical pattern. In such cases a border is usually arranged for. The tiles are bedded separately like ordinary tiles, but the bed prepared for them should be prepared with lime, not cement, and mortar floated to receive the tiles, which may be set with fine lime mortar.

A very beautiful marble floor, known as *Opus Alexandrinum*, is sometimes used, and was much employed in Italy during the mediæval period. In this work large, fairly thick slabs of a white or cream marble are used. Designs consisting of broad bands surrounding central square or circular figures are set out in the marble, and the face of these figures is sunk for a depth of about half an inch, and the spaces thus sunk are filled in with a kind of mosaic formed with richly-coloured marbles. The central circular sinking is filled with a thin slab sawn from a column, the broad lines of mosaic being separated from the centre and from each other by the original white surface of the main slab. Floors of great extent and magnificence have thus been formed. A splendid example is to be seen in the choir of Westminster Abbey, London, and in many Italian churches [136D].

The use of marble in the form of mosaic and terrazza floors has been already dealt with [see page 2516].

**Special Uses of Marble in General Building.** Where there is no general use of marble in a building, it is not infrequently introduced for certain special work, and the purposes for which it is most frequently used are the following: Hearths may be formed of slabs of marble varying from  $\frac{3}{4}$  in. to  $1\frac{1}{2}$  in. in thickness, and these may be provided with moulded kerbs of marble; such a kerb is sometimes used with other than marble hearths. The kerbs are made in as few pieces as possible, dowelled with slate or copper dowels to each other, and to the hearth, or the concrete under it, and set in stone-dust and lime. The edge may be rebated to fit over the hearth; if angles occur, they are worked and mitred on the solid block to fit up against the next block.

**Chimney-pieces.** Marble chimney-pieces are very much used. The best of these employ solid marble, often of a pure white, which allows of carving or sculpture being judiciously applied but cheap chimney-pieces are made up from thin slabs of marble which are blocked out and set with plaster of Paris and secured to the wall with copper cramps. Some of the cheaper classes of marble are much employed for such work, the slabs used in the jambs and frieze being generally from  $\frac{3}{4}$  in. to  $1\frac{1}{2}$  in. thick; the shelf at the top, the edge of which is moulded, is usually thicker. The boxings should be solidly filled in, or smoke may penetrate and discolour the marbles. Slabs of marble with a moulded edge are often used to form the bottom of a niche or arched recess in a wall, and for the tops of casings to coils and hot-water pipes.

**Lavatory Tops.** Lavatory tops are often made of Sicilian and more expensive marbles; a perforation must be made, and the edge of this is rebated to receive the rim of

**186. THE USE OF MARBLE: SOME EXAMPLES FROM FAMOUS BUILDINGS**

 Palace (staircase). F. Venice, S. Maria dei Miracoli (marble seat and lining in choir)

the basin. Sinkings are also dished out to receive the soap, and there is frequently a small skirting of marble run round the back and sides of the slab where it abuts against a wall. The skirting may be let into the slab with a rebated edge, and is fixed against the wall with brass screws, for which perforations and counter-sunk heads are required in the marble, and wood plugs must be driven into the wall. The main slab is usually carried by brackets of iron or a skeleton-framed top [see JOINERY]. Staircases and single steps and also thresholds are frequently formed of marble. The latter are particularly suitable in combination with a mosaic or terrazzo floor. As a rule, such steps are built up with treads and risers of marble, owing to the extreme cost of solid marble steps, especially if provided with a moulded nosing, which involves sinking the whole face. Such built-up steps must have a solid core of stone or lime concrete, or even brick. The risers are usually about 1 in. thick, the treads about 1½ in. thick, and such a tread may have a moulded nosing formed at comparatively slight expense. The slabs are usually set in stone-dust and lime. It is not desirable to polish either steps or landings, or floors executed in marble, as it renders them slippery, but it is sometimes done to enhance the effect of the marble. The surface should be finished with fine sand, which leaves the marble somewhat duller in appearance, but is much more safe and suitable for traffic.

**Slate Masonry.** Slate in the form of slabs is used for many purposes in connection with buildings, and is valuable for its great strength, especially under shearing stress. It is the same material as is used for roof slating, but is much thicker. This form of slate is supplied as *self-faced*—that is to say, just as split, with a fairly even but not perfectly true face, or as *sawn slate*, which still has a rough surface, but one that is fairly true. It may also be *quarry-planed*, possessing a finer surface, or it may be finally *rubbed*. The edges of the slabs may be *sawn square* or *planed* or *rounded*.

Slate will not take a high polish like marble or granite, but becomes very smooth and glossy, with a close, even grain. It is almost non-absorbent, and is used for shelving in larders, where such properties are of great value, and the small thickness occupied by such shelving is a further advantage.

It is used as split in slate districts for landings, thresholds, and steps, and for such purposes is usually about 2 in. thick; it is also used for window sills, but differs in form from a stone sill, and consists of a slate slab set at an angle so as to throw off the rain.

Wine-cellars are often fitted up with split slate shelves supported on half-brick piers, which should not, as a rule, be more than 5 ft. apart. Where the slabs are jointed, a simple butt joint is used, which should occur directly above one of the piers.

For larders, bread and vegetable stores, and similar rooms the shelves are usually about 1 in.

thick, with rounded edges, and with the upper surface and the edge rubbed. Where joints are required, they are rebated and put together with oil cement. Such shelves are often not pinned into the walls, but kept clear of them, a space of about 1 in. being left for ventilation. They may be supported by glazed brick piers, or on cantilevers of iron, or of rubbed slate pinned into the wall in cement [182]. The bottom shelf in a tier of shelves is sometimes not kept clear of the wall, but pinned into it, and if the wall be plastered, may have a small kerb or skirting fitted above it all round; such a skirting is usually about 6 in. in height, and ¾ in. to 1 in. thick, and may be secured with brass screws, as described for a marble skirting.

**Slate Divisions.** Slate divisions are sometimes formed for baths and for urinals, usually about 1 in. thick, and the thinness of such partitions where many occur is a great economy of space. In urinals they may be employed for divisions between successive stalls, and are very frequently enamelled either in a plain tint or to imitate marble. Enamelling is executed by first painting the slabs with a ground coating and burning it in; the surface is then rubbed down and decorated as required. It has then three successive coats of enamel, of which the first is heated and rubbed down, and the second and third are successively burnt in at a temperature of from 300 to 600 degrees, and it is finally polished. Enamelled slate will stand for a considerable period, even if used externally.

With the modern standard urinal they are used to cover the front between adjacent standards, and to cover the top of them in many cases also, and are generally screwed to wooden wall plugs with copper screws, for which perforations with countersunk heads are provided. Slate lavatory tops are used, and are prepared in the same way as the marble tops already described, and fitted with a slate skirting.

**Slate Cisterns.** Cisterns of slate were at one time much used, and are cleanly, but being of very great weight and expensive, are not very generally used now; but in connection with brewing, slate is largely used for the settling backs, which are practically cisterns. The bottom of the cistern is formed in a single slab, 1½ in. to 2 in. thick, grooved to receive the walls. These walls are usually 1 in. to 2 in. thick, and are formed with two sides about 4 in. longer than the outside dimension of the cistern, and are grooved about 2 in. from the end of the slab to receive the remaining two sides. Holes are also drilled, and the two ends are fitted into the groove in the sides and put together with red lead cement; galvanised iron rods are passed through the holes, fitted with nuts and washers, and screwed up tight [181]. Any holes required for pipe connections must be drilled in the slate sides. Slate sinks may be formed on the same principle, but are comparatively little employed.

Some amount of *sawn slate* is used in connection with roofing, but is referred to in the section on Slating and Tiling.

Continued from  
page 3077

By JUSTIN MCCARTHY

EDWARD III. was followed by Richard II., son of Edward the Black Prince and grandson of the late sovereign Richard, who was born at Bordeaux on January 6th, 1367, was only a child when he succeeded on June 21st, 1377, and the government was put into the hands of a council of twelve of which John of Gaunt soon obtained complete control.

**The Boy King.** The boy King began his reign under trying conditions. The war still going on with France had exhausted the finances of the country, famine had spread over many parts of the land, and one of its habitual results, pestilence, had worked terrible ravages. There had been great uprisings of the peasantry in many agricultural districts, organised with the hope of compelling the Government, the aristocracy, the landlords and the wealthier classes to give the labourers means of obtaining food that they might eat of it and live. The council endeavoured to supply the wants of the State—the result of the cost of war and the extravagance of the Court—by the imposition of a new Poll Tax, an imposition likely at such a time to be felt intolerable by the mass of the people. An army of men from Essex and Kent, numbering, it was said, 100,000, marched upon the metropolis. The boy King behaved with promptitude and courage, and a judgment beyond his years. He went to meet the Essex division of the army at Mile End, and assured them that he would look into the causes of their complaints and would do his best to abolish the system which made them the mere serfs of their landlords, and to secure them the payment of regular wages for their services. The King's influence prevailed so far that the men of Essex declared themselves willing to accept his promise and return home.

**The Revolt of Wat Tyler.** The men of Kent, however, whom Richard had not seen, marched into London, destroyed the palace of John of Gaunt, who was held responsible by the public for all the troubles of the reign, made a wreck of Temple Bar, opened all the prisons they passed, broke into the Tower and put to death, amongst other victims, Simon of Sudbury, Archbishop of Canterbury. The authors of these outrages were chiefly under the command of Wat Tyler, and the fury against the archbishop had risen to its height because the men in revolt believed he had prevented the King from coming to meet them and hearing their grievances. Wat Tyler will always be remembered among the leaders of peasant revolts. According to traditions generally accepted, Wat Tyler was a blacksmith working at Dartford, Kent, where a tax-gatherer going

his unwelcome rounds to collect the Government imposts offered a wanton insult to the daughter of Tyler. Tyler struck him to death on the spot. Thereupon the great body of the peasant and working population in that region rose in revolt against the constituted authorities. Wat Tyler and a colleague of his, known as Jack Straw, became engaged in the movement upon London, and were amongst its most influential promoters.

**"A Socialist before Socialism."** A Kentish preacher, the Rev. John Ball, had been for some time a popular and powerful exponent of the cause of the poor, had denounced with impassioned eloquence the oppressive taxation, the inequality of class legislation, the wealth and dignities absorbed by the higher classes, the poverty and servitude inflicted on the lower. He was, in fact, a Socialist before Socialism had become a recognised movement in Europe. John Ball helped the popular movement in Essex and Kent, and was put into prison by the authorities at Maidstone. When the uprising peasants marched towards London they accomplished his release by force from Maidstone gaol, and probably the passionate feeling aroused by his imprisonment inspired the fury which led to the killing of the Archbishop of Canterbury.

The King, disregarding the influence of Archbishop Sudbury, had actually conferred with a large mass of the peasants who met him by chance at Smithfield. Wat Tyler was at the head of the peasants, and Richard endeavoured to convince them of the terrible dangers they were bringing even on their own cause by acts of violence and crime.

**Richard and the Peasants.** He told them that while peace must be maintained and crime punished he would do his best to procure a fair hearing for their rightful claims. An attempt was made to conduct a pacific negotiation, but fierce disputes took place. Some sharp words passed between Wat Tyler and the Mayor of London, William Walworth, which the Mayor brought to an end by striking his dagger into Tyler's body. Then shouts of "Kill, kill! They have killed our captain!" arose from the peasants. The young King rode boldly to the front and called aloud to the peasants that he would be their captain as he was their King, and that if they followed him he would obtain a hearing for their claims and endeavour to have justice done to them. The peasants took him at his word, and there came a peaceful interval, during which Richard did his best to obtain the removal of such grievances as he felt to be actual oppression. But this was a task which Richard was not able to accomplish fully,

## HISTORY

although his influence prevailed so far that John of Gaunt began to keep himself in the background, and, in 1386, withdrew to the Continent.

### Struggle between Barons and People.

The King was opposed in all his efforts by the influence of the barons, and it did not seem as if the serfs and peasants were very much nearer to the measures of justice he had endeavoured to obtain for them. The revolt broke out again in the eastern counties, and masses of peasants captured several of the nobles and ravaged their castles and demesnes. The death of Wat Tyler seems to have withdrawn from the peasants anything like union of action or reasonableness of policy, while the barons were convinced that by his removal the most dangerous enemy had been got out of their way, and that they could do nothing better than continue to force their policy on the young King. Richard made many efforts to obtain a constitutional and even a parliamentary settlement for the evil conditions oppressing so many of his people. But the struggles between the barons and the peasants only became sharper, and as Richard's years increased, his noblest qualities seemed to fade. He began to display a curious spirit of contradiction. When he had tried one policy for a time, he suddenly turned round and experimented in a directly opposite course. Having supported the peasantry so long, and finding that they continued to make war upon the barons, he joined the barons in the repression of them. Some of the severest measures for the repression of the revolt, some of the cruellest deaths and other punishments inflicted in the counties of Essex and Kent, were done with his approval and even by his orders. Each time he seemed to be convinced that the policy he was then undertaking was the policy best qualified to bring security to the throne and peace to the realm.

**The King's Dramatic Stroke.** He got into trouble with Scotland, and in 1385 he invaded that country and burnt Edinburgh to assert his power. Another coalition of the barons took place soon after, headed by the Duke of Gloucester, and planned for the purpose of open opposition to the King. The Duke of Gloucester was Richard's uncle, and under his leadership the coalition impeached many of the King's friends and convicted and executed several of them. On May 3rd, 1389, Richard suddenly tried a bold and somewhat dramatic effort to obtain the real sovereignty of the kingdom. He declared himself of age—which, in fact, he was although he seemed then to discover it for the first time—and announced that he intended to conduct his rule for himself whether the barons would or not. The immediate effect of this was wholesome and beneficent. He did not make any effort as a result of this declaration to assert an arbitrary rulership, but governed the country as a constitutional monarch, and did his best to extend the representative capacity and powers of Parliament. The country had some eight years of comparative peace and prosperity.

**Despotism and Abdication.** In 1394, Richard's wife, Anne of Bohemia, died, and within two years Richard married Isabella, daughter of Charles VI. of France. As the immediate effect of that union he seems to have become a thorough admirer of the French system of government, for he set about to rule England as if he were absolute monarch, with a total disregard for that parliamentary principle he had himself done so much to maintain. He accused some leading nobles of conspiracy against himself. Some were imprisoned, one died on his way to prison in France, one was executed, and the Archbishop of Canterbury was banished. The Duke of Hereford, John of Gaunt's son, was accused of treason and banished for ten years. The following year John of Gaunt died, and Hereford became Duke of Lancaster. Richard went to Ireland for the purpose of completing the work of conquest there, and the Duke of Lancaster, Richard's own cousin, was then prevailed upon by one of the banished archbishops to hurry to England and assert his own claims to the Crown. Richard hastened back to England, but he came too late. Henry, Duke of Lancaster, who had reached England at the head of only a small force, found that his army grew and grew as he moved towards the capital, where he received the support of some of the great families, and soon the Duke of York, whom Richard had left to act as Regent in his absence, allied himself with the forces which had arisen on the side of Henry.

When Richard had returned to England the cause was lost for him. He gave up all hope of recovering it, and resigned the crown. A formal impeachment of the King took place in Westminster Hall; Richard was dethroned by a solemn act of deposition and a vote from both Houses of Parliament declaring that result. Richard had completely worn out the patience of most of his people. He had gone from one extreme of policy to another. He was at one time an unqualified vindicator of the rights of the peasantry, and after a short interval went over to the side of the nobles. He had given much offence also by the support which he lent now to the Lollards and now to those who were for crushing them out of existence.

**The Lollards.** The Lollards were the first religious sect who had definitely set up as reformers of the State Church, the Catholic Church in England. These earliest reformers were followers of Wycliff, and are said to have derived their name from the German word *Lollen*. There were to be Lollard martyrs in England, but not in the days of Richard II. One of the main charges against Richard was that, owing to the influence of his first wife, Anne of Bohemia, he had encouraged the Lollards when they made their first appearance in England. It was Richard's fate never to retain the loyalty of any large body of his subjects. His reign passed away without a serious struggle. The country had grown weary of him, and was ready to welcome any successor whose coming might promise a settled administration. Henry of Lancaster was chosen as his successor.

on September 29th, 1399, and, according to the account generally received, Richard was put to death at Pontefract Castle on February 14th, 1400.

**The House of Lancaster.** Henry IV., the first King of the House of Lancaster, son of John of Gaunt, was born on April 3rd, 1367. His father was the fourth son of Edward III., and his mother the daughter of Henry, Duke of Lancaster. His reign was remarkable for many stirring events, but it has not left behind it the memory of an enlightened policy or of an exemplary ruler. It was a reign of almost unceasing war, foreign and civil. There was constant hostility between England and France, and the French made frequent descents upon the English coasts. There was much squandering of money, and many attempts were made by Parliament to put some check, by means of a council of "war treasures," on the expenditure of the national resources. At one time, Parliament proposed to confiscate the property of the clergy—Church property—to maintain the finances of the State. Henry refused to entertain this suggestion, and, indeed, there seemed something grimly farcical in the proposal that the Church and the clergy should be deprived of their revenues to meet the expenses of wars brought about by statesmen and soldiers. Henry did not confine his support of the Church merely to this action; he encouraged the severest measures against any who were considered heretics, and many were burnt during his reign.

The Welsh refused to sacrifice their national independence to English rule, and, under their celebrated leader, Owen Glendower, maintained a war against the King, in which, for a while, they had the assistance of France. Henry invaded Scotland and besieged Edinburgh Castle, but had to retire because, it is said, the agricultural condition of Scotland did not furnish means for the maintenance of his army. While Henry was engaged with his struggle with the Welsh, the Scots broke into Northumberland, but were there encountered by the Earl of Northumberland and his son Henry Percy, famous as Harry Hotspur. Shakespeare has made him a living figure, and one of the most spirit-stirring speeches in the historical plays is that of the humorous and daring Hotspur in the opening of "Henry IV."

**Harry Hotspur Defeated at Shrewsbury:** Hotspur and his house, believing that they had been wronged by the King, entered into a league with the Scotch and Welsh leaders against him; but the King met them at Shrewsbury, where they were defeated, and Hotspur was left dead on the battlefield. In 1406, Prince James of Scotland was captured while on his way to France, where his father, Robert III., had sent him for safety. The vessel was seized by an English cruiser, and James was carried a prisoner to London, where

he was kept by Henry IV. in honourable captivity, and instructed in the knightly and scholarly accomplishments needful for a prince of his time. Henry still kept up his struggles with France, but his character seems to have degenerated in his later days. He was an epileptic, and his maladies made him impatient, and even cruel. He died at Westminster on March 20th, 1413.

Henry, the famous Prince of Wales, the eldest of Henry IV.'s six children, succeeded him. He was born on August 9th, 1387, at Monmouth. He went through much practical study, and it is told that he revelled in wild adventure and extravagant amusement. The world knows Prince Hal in his younger days in Shakespeare's noble drama, "Henry IV.," and we imagine that not many readers would exchange willingly the Prince Hal of Shakespeare for the Henry, Prince of Wales of authentic history.

**Accession of Henry V.** The coronation of Henry V. took place on April 10th, 1413, and he opened his reign well by liberating some of his opponents in the struggle for the crown, restoring the son of Hotspur to his father's estates and dignities, and ordering the burial of Richard II.'s body in Westminster. Henry was a high-minded and, on the whole, a merciful man, although not always merciful towards the Lollards and others who still spread the doctrines which he was taught to regard as heresy.

The great fame of King Henry's reign, absorbing every other worldly credit attaching to it, is found in the stories of his wars with France. The Kings of England had through several generations claimed the rulership of some parts of France. The time was yet far off when such claims were to be abandoned. Some tempting opportunities now presented themselves as if for the purpose of inviting Henry V. to renew and enforce the claims of England. Charles VI. of France, who was then ruling—or, at least, allowed to occupy the throne—was sinking into insanity, and was destined to close his life as a mere madman. Under this hopeless rule, the great princes and nobles of France had divided into two parties, one, the Burgundian, led by the Duke of Burgundy; while the other followed the Duke of Orleans, called the Armagnacs, from the Count of Armagnac, father-in-law of the Duke of Orleans.

Henry V. had probably persuaded himself that he had a title to great states in France, and even to the French crown, from his great-grandfather, Edward III. He had, however, no valid title, and the attempts made by Edward III. had been caused by the continuous attacks made upon him from the French side of the Channel. Henry alleged that a truce with France for a definite time had been made by Richard, and that the time had now arrived when either the truce must end or terms of settlement be offered on behalf of the French monarchy.

# MAKING THE EMBANKMENT

The Contractor's Track. Locomotives and Waggon's at Work. Finishing the Earthworks. Retaining Walls. Draining and Preserving the Embankment

By R. W. WESTERN

THE earth is conveyed from the place where it is dug to the tip-head in waggon's, of which there are two kinds—end-tip and side-tip waggon's, the uses of which have already been described, and 15 and 16 give us a sufficient idea of their form and the arrangement of their parts.

**Temporary Way.** It is usual to provide a temporary railroad for these waggon's, and the rails to be used subsequently in the permanent way are sometimes laid down. The objection to this, however, is that the rough work of conveying earth upon ill-laid temporary roads is very apt to lead to the bending and distortion of the rails. The gauge of this temporary road is usually 4 ft. 8½ in., though this is rather on account of the convenience of using a standard gauge than for economy. Figs. 17 and 18 show contractor's temporary lines. The former includes a bridge made with a second arch so that the railway may be made four-track wide without unnecessary expense. If locomotives and trucks for a narrower gauge of either 3 ft. or a metre were ready to hand, the work could, in most cases, be done more economically by means of them. The rails for temporary purposes may weigh from 36 lb. to 56 lb. per yd., and are of the ordinary Vignoles section [19]. These rails are laid upon sleepers, the dimensions of which are 8 ft. or 9 ft. by 8 in. or 9 in. by 4 in. The dimensions naturally vary considerably, and old sleepers discarded from a permanent way of an open railway are frequently used. The sleepers are placed at distances apart which depend on the nature of the soil on which they are laid.

16. SIDE-TIP WAGON

In slushy places they will be nearly touching each other, and on hard ground as much as 3½ ft. apart. If laid at a greater distance than 2 ft. 6 in. apart the sleepers, however, will suffer severely from the pressure of the rail upon them.

**Rails.** The rails possess considerable strength as girders, and do not bend very much in a vertical plane. The chief cause of the distortion of the

rail is the accidental derailment of the earth-filled waggon's, and such accidents take place very frequently on the roughly-laid temporary road.

The rails are fastened down to the sleepers by large nails about 3 in. long. These dogs, as they are called, have a chisel edge, and are so driven that the edge is placed across the grain of the wood. In driving the dog the fibre of the wood is thus displaced longitudinally instead of latitudinally, thus avoiding any tendency to

15. END-TIP WAGON

split the sleeper. The form of these nails is shown in 20.

Two dogs are placed in each sleeper, but not opposite to one another, as this would increase the likelihood of the wood giving way. Attention should be paid to the position of the dogs. In 21, A B represents the rail. If the dogs, instead of being driven as shown in the figure, were put as indicated by the open lines, the rail when bent laterally, so as to be convex towards the bottom of the page, would be loosened from its fastenings. The dogs, therefore, are always knocked in as shown in the figure, those on the opposite rail being in the same position reversed, so that the sleeper is kept at right angles to the rails.

**Sleepers.** When the sleepers have been taken up and replaced several times—and such changes are necessarily very frequent on the temporary road—the dogs must always be driven in at a fresh place.

In time the wood of the sleepers becomes much weakened. Three dogs are often necessary, in which case it is usual to put two alternately on the inside and on the outside of the rail. When the timber of the sleepers no longer seems equal to holding them with sufficient firmness to secure the rail, planks may be laid down upon the sleepers on the outer side of the rail, and after being pressed against the rail may be nailed down on to the sleepers, forming a strong lateral support. This course is specially useful at crossings, where abrupt changes in the direction of the waggon cause considerable side pressure on the rails.

**Laying the Rails.** The length of the rails will vary from 15 ft. to 30 ft., and numbers of shorter lengths will be required for junctions, at the tip-head, and also where the steam navvy is at work. In laying them, the ground is first levelled; the sleepers are then laid down in place at a distance apart which depends upon the nature of the soil.

The rails are then placed upon them, two or three men carrying each rail and laying it upon the sleepers. The ends of the rails are then fixed by knocking dogs into the sleepers nearest their extremity. The rails are afterwards similarly fixed to the intermediate sleepers. The rails are kept at the right distance apart while being laid with the help of an iron bar provided with projections at right angles to it. This is laid across the rails, care being taken that it is at right angles to both of them. The projections are notched at their extremity, to enable the distance between the rails to be diminished at the points and crossings, where too much clearance between the inside of the rails and the flanges of the wheels passing over them is dangerous.

When the sleepers sink into the earth and the rails get out of level, the former may be *packed up*, as the operation is called, by shovelling earth beneath them.

The rails are joined together by means of fish-plates, forming a joint, an illustration of which is given in 22.

### Slewing.

When for any reason the temporary line of rails should be moved on one side, the operation is performed by a gang of ten men provided with crowbars—i.e., long straight bars of iron with a chisel end. First they move the earth from the end of the sleepers on the side towards which they are to be moved, so as to prevent obstruction. Then they get into position, five men at each rail, standing with their backs to the direction of movement with their crowbars between their legs. The crowbars

are then put underneath the rails, between the sleepers, and, using them as a lever and the earth as a fulcrum, the men heave, raising the end of the bar in their hands. This raises the rails and the sleepers together, and the whole structure slips on the crowbars as they tend to the vertical position, so that the whole road is shifted laterally in the direction desired.

It will be found that for the temporary railroad broad sleepers are a mistake; they are apt to be placed further apart than narrower ones and to rock as a train goes over them. This loosens the dogs and works away the earth from beneath them.

When it is necessary to remove the temporary road, the bolts are taken out

of the fish-plate and the dogs drawn from the sleepers. For the purpose of drawing the dogs, the men should be provided with special levers, having a curved bifurcated fork at the end, to engage in the ears of the dogs. By this means the dogs are very easily drawn out, and unless this instrument is at hand the men will endeavour to remove the dogs with a pickaxe, doing considerable damage to the sleeper.

### Points and Crossings.

The points and crossings used on the temporary line are similar to those required for the permanent way, a full description of which is given under that head, but as a makeshift the arrangement illustrated in 23 is frequently used. A and B are pieces of rail about 9 ft. long, hinged at A<sup>1</sup> and B<sup>1</sup> by means of loose fish-plates. This enables them to be set in line with the rails passing to E or with the rails passing to F.

Of these the right-hand rail of the one is at a distance from the left-hand rail of the other, and vice versa, such that as on reaching AB the flanges of the wheel can just pass between. CD is a short piece of rail hinged in the same way, and when in position, as shown in the figure, it passes over the other rail which it crosses.

From what has already been said it will be

17. CONTRACTOR'S TEMPORARY TRACK

18. CONTRACTOR'S TEMPORARY LINES DURING THE CONSTRUCTION OF A RAILWAY

seen that the temporary road used for shifting the earth is neither very strong nor very carefully constructed; indeed, it would be un-economical to make it any better than is absolutely necessary for the work. It is consequently unsafe for an engine to be pushing a line of waggons, whether full or empty, at a high speed upon the temporary road.

**Position of Locomotive.** As it is important for the locomotive drawing a train to be always in front of it, many devices are adopted to change the position of the engine from the rear to the front of the train. The most obvious method is that illustrated in 21. The engine merely shunts the train into a siding communicating at both ends with the main line, and then detaching itself goes back and returns via the main line to re-attach itself at the other end of the train.

**Reversing the Locomotive.** The method described does not reverse the engine—which can be reversed, in the absence of a turntable, only by means of such an arrangement as is illustrated in 25. The engine, it will be seen, is reversed by running over the triangle. Frequently the engines are not reversed from the beginning of a job to the end, though unless there is an arrangement to strow sand on the rails both in front and behind the wheels great inconvenience is caused.

It may happen that there is no siding sufficiently long to accommodate the train and communicating at each end with the main line at the spot where it is necessary that the locomotive should be changed from end to end of a train. Under such circumstances, means such as that illustrated in 26 may be employed. The line CA leads, perhaps, from the place where the steam navvy is at work, the engine is drawing the train from A towards C, but desires to take it in the direction CD. In the ordinary course

reverses, and, putting on steam, runs along BD towards D, passing C before the remainder of the train, still moving by virtue of its initial velocity, arrives there; at D the engine stops while the waggons slowly pass over the junction C and come to a stop at B, when the engine

can again be attached, and at the right end. This method, which is very convenient and obviates the necessity for a special siding, requires for consistent success that there should be a moderate slope from A to B to prevent the waggons from losing their speed too

quickly. The waggons may otherwise come to a stop when only half over the junction of C, especially if a long train is being dealt with, thereby causing considerable delay and confusion.

Another common way to effect the same thing

may be illustrated from the same figure. An engine pushing a train of waggons from B towards D desires to change its position to the front of the train. CD may be a siding on an upward slope leading to a quarry or spoil bank. The engine pushes the trucks up CA with some speed, but detaches itself before reaching C, and slows down. After the waggons have passed on to CA the points are altered, and the engine runs on to CD. The waggons, after coming to rest, run back of their own accord and come to a stop on CB, when the engine can reconnect itself at the right end. This process may be reversed and the engine be returned again to the former end of the train, as is often necessary when

waggons have to be pushed up a steam navvy which might be working in a blind end at A. In these cases, as before, there is danger of the waggons stopping when but half over the junction. Manual labour must then be resorted to, and the trucks moved separately by levers between the spokes.

### Derailment of Waggons.

On the temporary line of way waggons containing earth are frequently derailed. The first thing to do in an accident of this kind is to

disconnect the waggons from each other, then the engine, supposing it to be still on the line, as usually happens, proceeds to exert itself on the nearest truck off the line, provided the lower wheels and framework are entire. It is not difficult to get that wheel on to the line which

19. RAIL OF VIGNOLES SECTION

20. DOG SPIKES

21. FIXING RAILS WITH DOG SPIKES

22. FISH-PLATE JOINT

23. MAKESHIFT POINT AND CROSSING ARRANGEMENT

of things, being already in front of the train, it would be necessary to push it towards D, and to avert this the following manoeuvres are performed. The engine, while coming along AC at the head of the train, is detached, and, increasing its speed, runs on to B. Here it

has come off on the inside of the rails, or it would not be so if it were not on account of the other wheel which has necessarily gone off on the outside of the rails so that the flange of the wheel is in the way in replacing it. In every case the method adopted is to extemporise an inclined plane on which the flanges of the wheel can roll, by means of loose sleepers and blocks of wood, roughly hewn for the purpose. The

engine is used to pull the nearest waggon up the incline

till the bottom of the flanges of the wheels are on a level with the top of the rail, when they can be slipped on to them. Such an operation can often be performed without the necessity of emptying the waggons.

**Reversing Waggons.** Although it often happens for want of means of reversing that the locomotives may continue at work with their funnels in one direction for a considerable time, this can seldom apply to the waggons, otherwise end-tip waggons could be used only to tip at one end of the advancing railway, and side-tip waggons only on one side of the railway. A contrivance, therefore, is absolutely necessary for reversing waggons, though it be too lightly constructed for the reversal of engines, or even for the waggons themselves if loaded. A sketch of one of these is given in 27. The two circular pieces, B and C, slide upon one another while revolving on a bolt passing through centre of both. The contiguous surfaces

are greased so as to diminish friction. The two rails are thinned out at their longer extremity so that when this arrangement is placed between the rail of the temporary way these extremities can be lowered upon the latter and the waggon run up upon them until its centre of gravity is approximately just over the central bolt, when two men can easily lift the extremities of the rail, and cause the circular piece B to revolve upon C. The thinned out extremities of the rail are then set down on the other side, and the waggon allowed to roll off on this opposite side.

**Cuttings and Embankments.** The lateral stability of a cutting or embankment is secured by sloping the earth away or supporting the side by means of retaining walls. The former, being the cheapest and most general, will be considered first. The slope adopted for cutting may usually be steeper than that for embankment, since the material of a tipped

embankment is not found to hold so firmly together as the undisturbed earth at the side of a cutting. The most common slope for general purposes in cuttings is one to one, and for embankment one and a half to one.

**Trimming.** As already pointed out, the slopes of cuttings are usually trimmed to the ultimate profile with greatest economy shortly after excavation by

means of a steam navvy  
has been  
com-  
pleted.  
It is, how-  
ever, fre-  
quently a  
waste of

labour to do more than remove roughly the surplus material from the side of the cutting, since slips may subsequently occur which will require a more accurate trimming to be done over again. This is especially the case in a clay soil, as the behaviour of this material, when exposed to the weather, is often very treacherous. Embankments being liable to settlement or shrinkage, it is advisable to allow a considerable time after tipping before the trimming is completed, unless the degree of settlement or shrinkage can, by experience, be so well gauged as to enable the sides to be trimmed to an angle which will subsequently come to be that of the proper profile of the embankment.

The process of trimming is performed, first of all, by dressing the slope to the correct angle and position at places from three to four chains apart. Where the line is on a curve, they must, of course, be made more frequent. The slope is

obtained by means of a triangle, called a *batter* [23], provided with a plumb-bob in its shortest side. The proper position and angle of the slopes having been obtained at short distances apart, the earth is readily trimmed evenly between them. To avoid subsequent slipping of the material, it is frequently found necessary to drain the slope by means of ditches 2 ft. or 3 ft.

wide, and from 9 in. to 18 in. deep, which may be filled with rubble stone, or with bricks. These usually extend about three-quarters of the way up the slope, throwing off two or more branches sloping upwards towards the top.

**Soiling.** When the slopes have been trimmed, and any necessary drains completed, the surface is advantageously covered with a layer of vegetable soil, 6 in. or 8 in. deep. This soil is best obtained by removing the surface

24. COMMON ARRANGEMENT OF LINES FOR SHUNTING

25. SHUNTING ARRANGEMENT FOR REVERSING ENGINE

26. EMERGENCY SHUNTING ARRANGEMENT

of the ground to the same depth before excavating or tipping upon it. In most cases, the amount of soil thus obtained will be amply sufficient for covering the slopes to the same depth, and in a grass country sods may be cut from the original surface of the ground and stored, to subsequently cover the slopes.

If  $x$  [29] measure to the height of an embankment, and  $y$  its breadth at the top, also  $n$  the co-tangent of the angle of slope, then, in the case where the quantity of surface soil is no more than sufficient to cover the slopes,

$$y + 2nx - 2x\sqrt{n^2 + 1}; y = 2x(\sqrt{n^2 + 1} - n)$$

$$x = 2(\sqrt{n^2 + 1} - n).$$

As it is obvious that, in the case of a very low embankment, the surface soil would more than suffice, it is evident that this value of  $x$  represents the greatest height to which an embankment could be carried if the soil required for the slopes were entirely provided from the original surface excavated to the same depth.

$x$  is smallest when  $y$  is least and  $n$  is greatest, so that the most unfavorable case would be that of a single line of way on an embankment with gentle slopes. Taking, therefore, the former at 16 ft and the latter at 2, we find that

$$x = \frac{8}{\sqrt{5} - 2} = 35 \text{ ft nearly.}$$

The process of laying the soil upon the slopes is more difficult in cuttings than upon embankments, in spite of the fact that in the latter case the soil has to be got up the sides, and in the former it has only to be let down. The reason for this is that the slope on the embankment is always less than that of a cutting excavated from the same material, and when the earth is thrown with the spade on to the side of a cutting of the usual slope, about one to one, a large portion of it will begin immediately to roll down to the bottom. Thus, in soiling the slopes of cuttings it is usually necessary to place boards at intervals horizontally along the slope, and by means of stakes to erect them, and maintain them at right angles to the slope, while the soiling is being carried out.

**Soiling.** When the soiling is complete, the sides of the slope are sown with grass. About three bushels of grass seed will suffice for an acre of the slope. A common mixture

of seed consists of 1 lb. of clover to 2 lb. of rye grass.

The object of the grass is to protect the sides of the slope from the denudation of rain and water. The grass presents its leaves, and thus protects the soil beneath it, at the same time binding it together with its roots. The object of soiling is to assist the growth of the grass,

and as the soil is in greater danger of being washed away before the grass has grown sufficiently to protect it, it is undesirable that the soiling of slopes should be proceeded with too long before the time of

27. CONTRIVANCE FOR REVERSING WAGGONS

year suitable for growing the grass.

**Retaining Walls.** When it is decided, either on account of the nature of the ground or because of the value of the land, to support the sides of a cutting or embankment by means of walls, they may be built in the form shown in 30, according to the following rule.

If the wall be not surcharged—that is to say, if the earth behind the wall be level with the top of it, the thickness of the wall at formation level should be made two-fifths of  $H$ , the height of the wall above this level. If, on the contrary, the wall be surcharged, and the earth rises above the top, the length  $H$  should be set

off up the slope, as shown in the figure, and its vertical projection added to  $H$ , so as to make  $H'$  as shown in the figure; two-fifths of this is then taken as the thickness of the wall at formation level. Formation level is, of course, the level of the ground upon which the permanent way is laid, and in the case of embankments, the ordinary level of the country applies instead of it. It will be seen by the figure that the retaining wall is built on a bed of concrete.

It may be necessary to vary the quantity and thickness of this

according to the nature of the soil in which it is built. The cost of concrete is not

29 DIAGRAM ILLUSTRATING THE SOILING OF AN EMBANKMENT

usually less than that of brickwork, but the reason for using concrete for the foundations of retaining walls rather than extending the brickwork lower down is that the concrete can be put in without disturbing the earth at the side. This could not be done with brickwork, and as retaining walls usually fail by sliding forward bodily rather than by being overturned, it is desirable to have the earth opposing this movement in the firmest possible condition, and this

is provided by leaving it in its undisturbed natural state.

**Preservation of Earthworks.** In addition to soiling the slopes of cuttings and embankments, it is economical to round off the toes and shoulders of the work, to pave the ditches, and to provide tile drains for the sub-surface drainage. The original coat of doing this is, however, considerable, and is often shirked, in spite of the fact that the work is fully justified by the subsequent saving effected in making good the effects of weather and floods, etc.

The greatest care should be taken that the top of an embankment does not become hollow like a trough. It frequently happens that the sleepers of the temporary road are packed up with earth at the ends, leaving a longitudinal depression in the centre. Before the permanent way is begun, or before the ballast is brought on to the line, this matter should be looked into, and the hollow, if present, should be filled with earth and rammed tight, otherwise it will be filled with ballast and perpetuated. After heavy falls of rain the water will then collect in pools beneath the sleepers, and ultimately work its way into the bank, softening it and causing spue-outs of earth below, and subsequently cracks and slips in the earthwork. This state of things once established is very difficult to remedy.

**Erosion of Banks.** In places where floods are liable to take place, provision must be made to carry the water rapidly away, and to prevent damage to the banks by

erosion. Flat stones on edge—i.e., with their longest dimensions at right angles to the surface of the earthwork, and their next longest dimension in the direction of the flow of the water—afford the best protection. When the base of a bank is liable to be eroded by the wash of waves—not sea waves, but the wave action of large sheets of water—a sufficient protection is often afforded by making the slope very flat.

**Drainage.** The secret of maintaining earthworks economically depends on the drainage. It must never be forgotten that wet earth and dry earth are two materials whose properties are different—often very different. Some clays, for example, though hard enough and

rent in example, stiff enough to make excavation difficult, become by mere exposure to damp air a semi-fluid mass of treacherous consistency. Such material is, of course, worse than useless for any structure whatever; but every gradation exists, and it is frequently necessary to make a cutting in earth too treacherous to be used in the formation of an embankment. Under these circumstances the excavated material must be tipped to "spoil" or waste. Often land must be purchased to receive it.

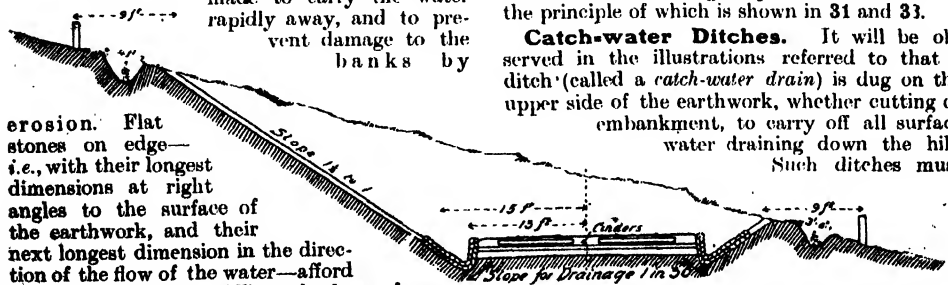

It must be remembered that the material used for embankment is subject to the endless pressure of its own weight, to disregard for the moment the pounding action of passing trains. Such pressures must be withstood while the earth is standing at an angle which is, as a rule, steeper than obtains in Nature. The side of a cutting made in a hillside is, for example,

necessarily steeper than the part of the hill in which it is made, and it may be steeper than the slope at which the earth will permanently remain under natural conditions. The only thing to do then is to insure that this earth be dryer than natural conditions would allow. Thus artificial drainage is provided in a manner the principle of which is shown in 31 and 33.

**Catch-water Ditches.** It will be observed in the illustrations referred to that a ditch (called a *catch-water drain*) is dug on the upper side of the earthwork, whether cutting or embankment, to carry off all surface water draining down the hill. Such ditches must

30. DIAGRAM ILLUSTRATING RETAINING WALL BUILDING

31. DRAINING A RAILWAY EMBANKMENT

have a sufficient slope longitudinally to prevent any water standing in them, and for the same reason should be periodically cleaned out. The

ditches provided on the lower side of an earthwork are not so important, since these have to receive only the small amount of drainage issuing from the earthwork itself. It will be seen also that the ground on which the permanent way is laid, or the formation level, is also sloped at 1 in 30, and in 33 a *stone faced drain* is provided to take off the water. This provision is not always necessary, though in wet cuttings even more elaborate arrangements may be desirable.

**Difficulties with Earthwork.** Most of the troubles arising from suitable earthwork must be attributed to the agency of water. A typical instance is illustrated in 32. Here we have a stratum of loam or marl containing a good deal of unctuous clay overlying a bed of hard rock, or some substance impermeable to water.

The result of this will be that the upper stratum will retain a good deal of water, of which a considerable amount will find its way down to the surface of the hard rock, and, being thus arrested, will remain to lubricate further any movement or slipping in this plane.

In its natural condition, the slope towards the river being very gradual, it may be that there is no likelihood of any movement taking place. But as soon as the cutting is made an entirely different state of things supervenes, and there is danger that the bed of marl or loam may slide into the cutting as fast as it is made and continue to do so until the whole side of the hill above it is brought once more to the natural slope at which it originally rested. Under these circumstances, the best plan is to drive a tunnel or heading some way back and higher up the hill, as shown in the figure, so that all water between the two strata is stopped here, and carried away to the nearest natural water-course. This device, accompanied by catch-water drains on the surface, will usually suffice to maintain equilibrium. A more expensive method would be to throw a brick

arch over the cutting and cover it in, thus re-establishing the former conditions as nearly as possible.

In the formation of embankments, all dangerous materials are, of course, avoided, and giving the railway the benefit of the doubt means discarding the material about which there is any question. But it frequently happens that the soil upon which an embankment is to be built is of a very difficult character to deal with.

**Chatmoss.** In the celebrated example of Chatmoss that was met with in building the first railway from Liverpool to Manchester, George Stephenson was confronted with something little better than a quagmire from 10 ft. to 35 ft. deep, and containing water to the extent of twice the

bulk of solid material. He formed a secure foundation for heavy railway traffic in the following manner. Drains were cut about every five yards apart, and when the moss between them was quite dry, it was used for the embankment. On this were laid hurdles in single or double layers, and over them the ballast. By thorough draining in this way, cuttings as deep as 9 ft., and embankments as high as 12 ft., were formed in a substance in which an iron rod would sink with its own weight. In addition to good drainage, the introduction of the hurdles effected a wide and uniform distribution of the weight of the earthwork. This is an exceedingly impor-

tant point in the formation of embankments upon treacherous ground. The effect of drainage is to strengthen the material by increasing its resistance to movement by slipping; but after slipping has once started, it is much more difficult to stop it than before it began.

**Earth Slips.** Slips take place in surfaces hidden within the material, and the particles of earth on these surfaces of slipping become turned as the slipping proceeds, thus loosening the material and affording readier access to the lubricating action of water, which immediately aggravates the slip.

An engineer must, therefore, proceed with his work so that no mass of earth has to sustain pressures sufficient to cause slipping to begin, in whatever condition it may be. A superficial slip—that is, a slip confined to the surface layers—is of small importance: a deep slip is naturally of greater consequence; but the most serious is a deformation of the earth caused by its particles slipping over each other in numerous surfaces throughout the mass, and this must be avoided by

preventing the appearance of any stresses sufficient to cause it.

ING A RAILWAY  
BANKMENT

If an embankment originally tipped in the form shown by the full lines in 34 subsequently assumes the form indicated in exaggeration by the dotted lines, it is in a very bad state. An immense amount of earth must be tipped before the requisite height is attained, for it will continue to spread out as the weight superposed increases. Had the bank been originally formed at an easy enough slope, slipping would never have begun, and all serious trouble might have been avoided.

Similarly, when the earth upon which the embankment is tipped is at fault, the effect of imposing the extra weight of the bank on the surface of the soil is to cause profound deformation. Fig. 35 shows a common type.

\* The soil sinks beneath the bank, but rises beyond its limits, probably causing damage to

### 32. RAILWAY WHERE WATER CAUSES TROUBLE

### 33. DRAINING A RAILWAY EMBANKMENT

adjoining property, and in any case vastly increasing the amount of earth to be shifted. Had the bank been originally made in stages, as indicated in 36, this difficulty would in all probability have been avoided.

**Tipping on Soft Ground.** The method in soft ground is to tip first the two small banks whose inner outlines are indicated by the dotted lines, thus distributing moderate pressures over a large surface of soil. Any tendency to movement of the soil would be in the direction of a rising between the two small banks. Of course, the appearance of such a thing would be a danger signal, showing the need for still wider distribution of weight; but the movement would not greatly weaken the soil in resisting the motion which the completion of the bank will most tend to bring about, being in a different direction. The slipping of this earth must be most carefully guarded against. It is a source of enormous expense.

**Tipping Doubtful Material.** In tipping doubtful material, any expedient calculated to remove water and keep it away should receive careful consideration. The work may even be stopped in wet weather. Snow should be removed before fresh material is tipped over it. In banks exceeding 25 ft. in height it is better to include no material regarding the subsequent behaviour of which there is any ground for apprehension. If, in spite of every precaution, a serious slip take place in an important earthwork, it will often be found cheapest in the long run to remove the whole of it and replace it with more stable material. The material removed may even be dried and burnt in heaps with coal or wood, and put back. This is a very fundamental cure, provided the whole of the bad earth be removed, since it converts it into one of the most satisfactory materials of which an earthwork can be made. But the expense is heavy, for, besides the cost of handling, the fuel required amounts to about a tenth of the weight of the mass if coal be used, or more if wood be used.

**Foundations for Embankments.** It is sometimes found necessary, in forming an embankment over soft ground, to make a foundation for this superincumbent mass by digging a trench of equal width, the sides of which are trimmed to the slope natural to the soft ground in which it is cut. This trench is then filled with stable material, and the embank-

ment made upon the top of it in the ordinary way. The cost of this procedure is, of course, very heavy, and it is important that it should not be undertaken unnecessarily, or where simpler devices would serve. In cases where it is decided to adopt the method it is necessary to calculate the required depths of the trench with particular care, as it is this dimension which determines both the efficiency and the cost of the work. The expression

34. SLIPPING OF EARTHWORK

$$\frac{hw \left( \frac{1 - \sin \theta}{1 + \sin \theta} \right)^2}{w' - w \left( \frac{1 - \sin \theta}{1 + \sin \theta} \right)^2}$$

gives the depth required in which  $w'$  is the weight of the soft ground,  $w$  is weight of the filling, both in lb. per cubic ft.;  $\theta$  is the angle of natural slope, or angle of repose, of the soft ground, and  $h$  the height of the proposed embankment.

**Settlement of Embankment.** The diminution in the bulk of artificially deposited earth begins at once and continues for years. Its amount varies very greatly according to the nature of the earth, its condition at the time it is put in place, and the manner in which this is done. The reduction in the height of an embankment which ultimately takes place from this cause is seldom less than 1 in. for every foot, and often amounts to twice as much. No rule can be given that is likely to be of practical use on the ground; but it is well to remember that earth will probably revert to the same density it possessed before it was dug in the first instance.

Allowance must be made for this in the construction of embankments, and these should in all instances be tipped so as to be of greater height at first than the plans and sections require by an amount which the experience of the engineer may decide to be necessary. In default of this, or if the experience of the engineer misguide him, the height will have to be made good by subsequent additions of earth.

This would not matter so much if the subsequent additions of earth were confined to the top of the earthwork, but the effect of settlement is to reduce the slope of the sides at the same time, and the consequence is that the top of the embankment becomes in effect narrower than it was.

Additional earth must therefore be placed on the side as well as on the top of the earthwork, and this addition of fresh earth to a slope already partially consolidated is not conducive to solidity.

# ELECTROLYSIS

Decomposition of Liquids. Electrolytes. Migration of Ions. Deposition of Copper. Laws of Electrolysis. Electrochemical Processes

By Professor SILVANUS P. THOMPSON

**ALLUSION** was made on page 463 to the circumstance that liquids conduct electric currents. All liquids do not; for the oils are non-conductors. Those liquids that conduct may be divided into two classes: (1) those like quick-silver and molten lead which conduct simply as metals; and (2) those which conduct only while undergoing chemical decomposition. To this last class belong solutions in water of innumerable salts such as alum, saltpetre, sulphate of copper (blue vitriol), and the metallic salts generally, acids, solutions of alkalis, fused caustic alkalis, and fused salts. Absolutely pure water does not conduct at all, but ordinary tap water, which contains small quantities of salts in solution, conducts, and is made a better conductor by adding a little acid or soluble salt of any kind.

**Electrolytes.** Any liquid of this class was termed by Faraday an *electrolyte*, which means that it is decomposed when electricity passes through it. A simple experiment will enable us to understand the fundamental fact. Place in a small glass vessel, as in 214, some water that has been rendered conductive by adding to it a few drops of sulphuric acid. Procure a small battery consisting of at least two cells, and with this battery send a current through the water by dipping into it the ends of the two wires which lead respectively from and to the battery. The wire by which the current enters the water is termed the *anode*, and that by which it leaves the water to return to the battery is the *kathode*. If these wires are of copper it will be found that, while the current is thus passing through the water, small bubbles of gas are given off at the kathode, while the anode becomes discoloured and will slowly dissolve, the liquid around it becoming of the blue tinge of copper sulphate. The bubbles which come off at the kathode, if examined chemically, are found to consist of hydrogen gas. This can be proved by collecting them in a test-tube and observing that they will burn. Let the experiment then be repeated, using bits of platinum wire to dip into the water, platinum being chosen because it is insoluble. It will then be noticed that bubbles of gas come off at both of the wires. The bubbles at the kathode are hydrogen, but those given off at the anode are oxygen gas. It is one of the most elementary facts of chemistry that water is a compound of hydrogen and oxygen, and in both these experiments water has been decomposed. When it is

required to collect the gases separately, with a view to measuring the quantities given off, the form of apparatus shown in 215 may be used. With this the measurements can be made with extreme accuracy, and by the first law of electrolysis [see later paragraph] this forms a fundamental standard by which current-integrating instruments can be calibrated. When used in this way, the apparatus is known as a *voltammeter*. When the copper wires were used in the water, the oxygen did not bubble off, because it joined itself to the copper to form oxide of copper, which was rapidly dissolved by the acid in the water.

**Electrolysis.** Decomposition of a liquid by the passage of an electric current through it is a sort of *electric analysis*; but this term was shortened by Faraday first to *electro-analysis* and afterwards to *electrolysis*. One of the most

214.

LIBERATION OF  
HYDROGEN FROM WATER  
A. Anode K. Kathode

fundamental facts about the electrolysis of liquids is that the liquid is apparently not decomposed all along the path traversed by the current in the liquid, for the products of the decomposition come off only at the electrodes, where the current enters or leaves the liquid. When any acid is thus decomposed, hydrogen gas is produced, and it apparently travels through the liquid, being carried invisibly along by the electricity, and is deposited at the place where the electricity leaves the liquid, namely at the surface of the kathode. If strong hydrochloric acid is decomposed by a current, hydrogen is given off at the kathode and chlorine gas at the anode. The substances such as oxygen, chlorine, sulphur, etc., which appear at the anode apparently travel through the liquid in the direction opposite to that in which the electricity is travelling, and others, including hydrogen and all the metals, are invisibly conducted through the liquid in the same direction as the electric current flows. There are various theories to account for this, but we need not trouble about them.

**The Ions.** Whenever electricity is passed through an electrolyte, some of the molecules are split up into two parts, which then travel opposite ways, one part going with the current to the kathode, the other part going against the current to the anode. To these travelling parts of the molecules Faraday gave the name of the *ions*, a term of Greek derivation which means the things which travel. In some cases the ions consist chemically of simple atoms,

as hydrogen, or chlorine, or copper; in other cases the ion may consist of a group of atoms such as  $\text{SO}_4$  or  $\text{CN}$ . Those ions which travel to the kathode are called *kathions*; those travelling toward the anode are called *anions*.

The following is a statement of a few electrolytes and of the ions into which they are decomposed:

| Electrolyte.                             | Chemical Symbol         | Kathion. | Anion         |
|--|-------------------------|----------|---------------|
| Water . . . . .                          | $\text{H}_2\text{O}$    | H        | O             |
| Concentrated Hydrochloric Acid . . . . . | $\text{HCl}$            | H        | Cl            |
| Common Salt . . . . .                    | $\text{NaCl}$           | Na       | Cl            |
| Sulphuric Acid . . . . .                 | $\text{H}_2\text{SO}_4$ | H        | $\text{SO}_4$ |
| Sulphate of Copper . . . . .             | $\text{CuSO}_4$         | Cu       | $\text{SO}_4$ |
| Cyanide of Silver . . . . .              | $\text{AgCN}$           | Ag       | CN            |

**Migration of the Ions.** According to modern views each such ion possesses an elementary electric charge, positive or negative, associated with the atom (or atomic group) of matter. A positive ion, consisting of an atom (of hydrogen or metal) associated with a positive atomic charge (or positive electron), will, when subjected to an electromotive force, travel in the direction of that electromotive force, while a negative ion, because it is associated with a negative atomic charge (or negative electron), will travel in the opposite direction, and will move toward the anode. It has been shown that each kind of ion migrates with a definite velocity, proportional to the number of volts per inch of path between the electrodes.

### Electrolysis of Metallic Solutions.

Another very simple experiment [216] in electrolysis is afforded by the decomposition of a copper salt, and the deposit of metallic copper. For this purpose procure an ounce or two of the blue crystals of sulphate of copper—often called blue vitriol—and dissolve a few of them in water, producing a blue solution. As they dissolve slowly, a strong solution cannot be made in a hurry. Procure also a few strips of sheet copper  $\frac{1}{8}$  in. broad and 4 in. or 5 in. long, and some similar strips of German silver. They should be carefully cleaned. Place the blue solution in a glass trough or a glass beaker, or even in a common jam pot, and add one or two drops of sulphuric acid to improve the conductivity. Use as source of current a single Leclanché cell. Connect copper wires to two of the copper strips, and join one to the carbon pole of the Leclanché cell, the other to the zinc pole. When all is ready, dip the two copper strips into the vessel containing the blue electrolyte, and watch what occurs during the next twenty minutes. If all is right, there will not

be any bubbles of gas given off, but a deposit of fine red metallic copper will occur on the kathode (the metal strip joined by wire to the zinc pole of the cell), while the copper plate that serves as anode will be observed to become discoloured, and some of it will be dissolved. In fact, in this experiment copper is dissolved away from the anode and an equal quantity deposited on the kathode. The equality between the amount of copper dissolved off the anode and that deposited on the kathode can be tested by weighing both of them before the experiment is made, and by weighing them again afterwards. The gain in weight of the kathode ought precisely to equal the loss in weight of the anode. If the current has been too strong in proportion to the size of the kathode, or if the solution has been too weak, the loss and gain may not be equal, owing to the evolution of gases as well.

After having thus deposited copper on a copper kathode, now try to deposit copper upon a strip of German silver. Take one of the German silver strips and make it clean and bright first by scouring it with emery paper, then cleansing it from any trace of grease with caustic soda, and then washing it with dilute sulphuric acid. Join it by a copper wire to the zinc pole of the Leclanché cell (or a Daniell's cell) and immerse it in the copper solution. As anode in this experiment a copper strip will be appropriate. In a very few minutes the white surface of the German silver plate will be found to be covered with a beautiful film of red copper firmly adherent to its surface.

In fact, it is now copper-plated. It is not advisable to try to deposit copper in this way upon a surface of iron or zinc, because these metals are themselves electropositive to copper. If copper is to be deposited on iron or zinc, an acid solution must not be used, but a special alkaline cyanide solution of copper.

### Laws of Electrolysis.

In the light afforded above by the paragraph on the ions, it is easy to see that there is a rational basis for the law of electrolytic decomposition first formulated by Faraday, that the quantity of chemical decomposition that goes on in any electrolytic cell is proportional to the total quantity of electricity that has been passed through the cell. So, if we know how much copper was deposited on the kathode by a current of one ampere in one hour, it becomes a simple matter to calculate by rule-of-three how much copper would be deposited by any other number of amperes in any given time that the current is maintained. Experiment shows

215 THE VOLTA-METER

Illustrating the method of extracting oxygen and hydrogen from water

## ELECTRICITY

that a current of one ampere maintained for one hour deposits 18.22 British grains, or 182 grammes of copper. Since 1 lb. equals 7,000 grains, it follows that to deposit 1 lb. of copper will require one ampere maintained for 384 hours, or 384 amperes maintained for one hour. The simplest way of stating this is to say that the deposition of 1 lb. of copper needs 384 ampere-hours. In the textbooks the electrolytic equivalents are generally given in terms of the number of grammes deposited by one ampere in one second. For copper this equivalent is 0.0003281 grammes.

Another of the laws discovered by Faraday is that when we compare different chemical elements with one another the amounts deposited electrolytically (by the same current for the same time) are proportional respectively to their chemical equivalents—that is, to the proportions in which in chemical reactions they are equivalent for exchange. The chemists take hydrogen as standard, and tell us that the amount that is

is "equivalent" for exchange purposes to one gramme of hydrogen is 31.59 grammes of copper, or 107.67 grammes of silver, and so forth. Hence we may construct a table of electrochemical equivalents as follows:

| Element. | Atomic Weight | Valency | Chemical Equivalent | Grammes per ampere-second. | Pounds for 1,000 ampere-hours |
|----------|---------------|---------|---------------------|----------------------------|-------------------------------|
| Hydrogen | 1             | 1       | 1                   | 0.0001048                  | 0.824                         |
| Copper   | 63.5          | 2       | 31.59               | 0.0003281                  | .27                           |
| Silver   | 107.67        | 1       | 107.67              | 0.0011181                  | .9                            |
| Gold     | 197.2         | 3       | 65.4                | 0.0006791                  | .537                          |
| Nickel   | 58.6          | 2       | 29.2                | 0.0003043                  | .241                          |

**Voltage Necessary for Electrolytic Decomposition.** If we try to decompose water with the use of a single Daniell cell, whose electromotive force is 1.07 volts, or even a single Leclanché cell, whose electromotive force is 1.5 volts, and terminal voltage, therefore, something less, we shall find that there is no evolution of gas at the electrodes if they are of a non-oxidisable metal, such as platinum, and that no current is carried through the liquid. If, however, we use two cells, the process goes on as already described. The reason of this phenomenon is that a certain minimum voltage (1.47 in the case of water) is required to break up the molecules of the liquid into its positive and negative ions, and so enable them to be deposited at the kathode and the anode. Under the influence of a voltage less than this the liquid is not conductive, and this voltage is a measure of the chemical affinity of the two elements or ions for one another.

If, however, electrodes of zinc or of copper are used, one cell will decompose the water because each of the oxidisable metals has an affinity for the oxygen of the water. Thus, for instance, copper has an affinity of about 0.8 volts for oxygen, and if a piece of copper is placed in water, or in a solution of a copper salt, it tends to dissolve into that liquid with an electromotive force of about 0.8 volts. It does not, however, dissolve, because it could only decompose the water by tearing away H from O, and this needs 1.47 volts. But if one Daniell's cell is applied, as in the experiment above, to the copper electrodes, the voltage of the cell adds itself to the affinity voltage of the copper anode, so that there is more than 1.47 volts acting.

### Energy Required for Depositing.

In electrolyting, where the anode and kathode are both copper surfaces, each tends to dissolve back into the liquid, these tendencies being equal and opposite. Hence, when even the smallest electromotive force is applied, it will cause a small current to flow from the anode to the kathode, for copper will be dissolved off at the anode, and an equal quantity will be deposited at the kathode. In a reciprocal action like this, the energy required is only that necessary to drive the current through the ohmic resistance of the liquid, and it all disappears in the form of heat. In other cases, where the anode and the metal deposited at the kathode, as, for instance, in the deposition of hydrogen in the electrolysis of water, a certain amount of work is required to overcome the chemical affinity of the constituents for one another, and an extra amount of energy is required which is transformed from electrical energy into chemical energy, which is rendered potential, and may be recovered and made to do useful work.

**Electrochemical Processes.** Apart from the deposition of metals, which is treated in the next lesson, there are certain processes which depend merely upon the electrolysis of solutions. Among these is the production of caustic and bleaching liquor by electricity from common salt. As shown above, salt is a chemical compound of sodium and chlorine. When a current is passed through a solution of it, chlorine is liberated at the anode, but the sodium which should be liberated at the kathode has such an affinity for water that it combines with it, forming caustic soda in the neighbourhood of the kathode, and giving off hydrogen. There are several difficulties in the commercial application of this process. Chlorine is to some extent soluble in brine, so that a porous diaphragm has to be arranged between the anode and kathode to prevent the mixture of the chlorine and the caustic soda. To further attain this end, the fresh brine is added on the anode side of the partition, and the soda is drawn off as it is formed from the kathode region. Another application of this principle is the treatment of sewage. In the ordinary way, sewage contains enough salt to ensure a copious evolution of chlorine at the anode when a current is passed through it. Now, chlorine is a good disinfectant, and by this means the sewage becomes deodorised by the presence of the chlorine, which becomes dissolved in it.

23

Deadeyes. Adjustable Bearings. Waggon, Carriage, and Locomotive Axle-Boxes. Babbitt Bearings. Brackets and Hangers. Speed and Power of Belts

TECHNICAL DRAWINGS  
continued from  
page 3137

By JOSEPH W. HORNER

**Bearings.** The simplest form of bearing for a shaft journal is illustrated in 56, and consists of a metal boss having a foot cast with it for convenience of bolting down; such a bearing is termed a "deadeye." It is chiefly used for slowly revolving shafts of hand-driven appliances; when wear takes place it is necessary to renew the bearing itself. Fig. 57 shows a similar deadeye fitted with a renewable gun metal sleeve, or bush, which is forced into place, and can be replaced when worn. Alternatively, such plain or bushed bosses may be designed as part of a machine framing instead of being separate pieces. A great drawback to the use of these bearings is the necessity for parallel shafts, and the inconvenience of removing all objects keyed thereon in order to get the shaft out of the bearings, for it must obviously be moved endwise.

**Divided Bearings.** The divided brass and adjustable cap are illustrated in 58. They have not only the advantage of being renewable, but by taking off the cap piece and one half of the brass

the shaft may be removed bodily; the bearing is also adjustable by the tightening of the cap bolts and the consequent closing of the brasses when wear has taken place. The cap is secured by studs and lock nuts; the brass has pegs cast on it which enter corresponding holes in the cap and seating in order to prevent turning; flanges are provided at each end to take the thrust of collars, etc., on the shaft. These bearings may be arranged as part of a machine frame or alternatively as a separate article. Fig. 59 indicates it in this latter form, when it is termed a *plummer block*, or *pedestal*; the cap bolts pass through the block, and have square heads fitting in square holes; the base of the block has facing strips provided, which facilitate the fitting of the pedestal in its place.

The proportions for 58 and 59 may be taken as follow:

|                          |    |                                   |
|--------------------------|----|-----------------------------------|
| Thickness of brass       | .. | $B = .1A + .15 \text{ in.}$       |
| Thickness of flange      | .. | $C = B$                           |
| Length of turned portion | .. | $D = 1.7 B$                       |
| Diameter of peg          | .. | $E = B + \frac{1}{4} \text{ in.}$ |
| Thickness of cap         | .. | $F = .4 A$                        |
| Thickness of cap         | .. | $G = .38 A$                       |

The brasses need not necessarily be circular in outside formation; in fact, many of the earlier types of bearings had hexagon-shaped exteriors. A good form is shown in 60, where the brass is square on the outside, and fits into a square block, the cap being made of mild steel; the whole bearing is bolted to the steel side-frame of a heavy steam crab. This example is taken from an actual working drawing.

**Adjustable Swivel Bearings.** A modern form of bearing used largely for line shafting is illustrated in 61. It consists of a cast-iron bearing divided on the centre line and held together by square-threaded screws at the top and bottom; the ends of these screws have concave heads which fit over correspond-

adjusted in a vertical sense by means of the screws which can be rotated with a bar inserted in the holes of their bosses. The screws can be locked in position by set screws, as shown in the

## 59. PLUMMER BLOCK

main bracket. The shape of the bracket varies considerably, according to requirements; the one shown [61] is arranged for bolting up to a wall

or column, but can easily be designed in the shape of the letter J, so as to bolt up to a ceiling joist or beam. The proportions may be taken as follow :

### 60. SQUARE BRASS AND STEEL CAP

Length of bearing if cast iron  $B = 4 A$   
 Length of bearing if brass  $B = 2 A$   
 Distance between bosses  $C = A + \frac{1}{4} \text{ in.} \times 2.75$   
 Depth of boss  $D = A + \frac{1}{2} \text{ in.}$   
 Diameter of boss  $E = A \times 1.8$   
 Diameter of screw  $F = A$

big convex projections on the central part of the bearing. The bearing is thus free to swivel radially, and at the same time can be

Lubrication is effected by means of the two oil holes, which are fitted with lubricators; sometimes an oil tray is suspended underneath the

bearing to catch the waste oil. In the case of the shorter brass bearings the screw is made hollow, and lubrication is effected through the centre.

### Railway Axle-boxes.

Another type of bearing is the railway axle-box, which has several unique features not found in ordinary bearings. The brass does not embrace the whole circumference of the journal, nor does it extend the full length. The load always comes on the brass in a vertical sense, and there is therefore no necessity for a lower half brass, its place being taken by a device known as a "keep," which prevents undue vertical play between the journal and the brass. When a train is travelling at a high speed or passing round a curve there is considerable movement sideways, which must be allowed for in the axle-box, otherwise the continual side thrusts would destroy it. Lubrication is also a most important factor to be arranged for.

### Waggon Axle-box.

Fig. 62 shows a standard waggon axle-box having a journal  $3\frac{3}{4}$  in. diameter by 8 in. long; the brass is  $2\frac{1}{2}$  in. wide by  $7\frac{1}{8}$  in. long. It is not held in place by any fastenings, but is simply placed in a recess, as shown, and kept there by the pressure of the load transmitted to the journal. End movement of the brass is prevented by the shoulders formed upon the central portion. The axle-keep is simply a  $\frac{7}{8}$ -in. diameter bolt. The top of the box is made with a rectangular recess for the reception of the bearing spring, which does not fit it tightly, but has a small clearance all round to allow for play. The whole box is guided in horn plates, and definite clearance is also allowed here. The chamber between the brass and the spring seat is filled with grease, which melts as the bearing becomes slightly warmed, and passes through the two holes which lead to the journal, and by such means a plentiful supply of lubricant is assured. A wooden shield is fitted to a shallow chamber at the inside end of the box in order to keep out

dust and dirt. The views illustrated comprise a longitudinal section of the box and brass showing the journal in external elevation, the

dust shield and the grease door being also shown in section; a half transverse section, AA, through one of the oil holes shows the shoulder on the brass, which prevents its end movement; a half transverse section, BB, on the centre line; a half plan; a half sectional plan; and two views of the brass.

### Carriage Axle-box.

A typical heavy bogie-carriage axle-box is illustrated in 63. The journal is 5 in. diameter by 8 in. long, and the brass is held in a slightly different

61. SWIVEL BEARING

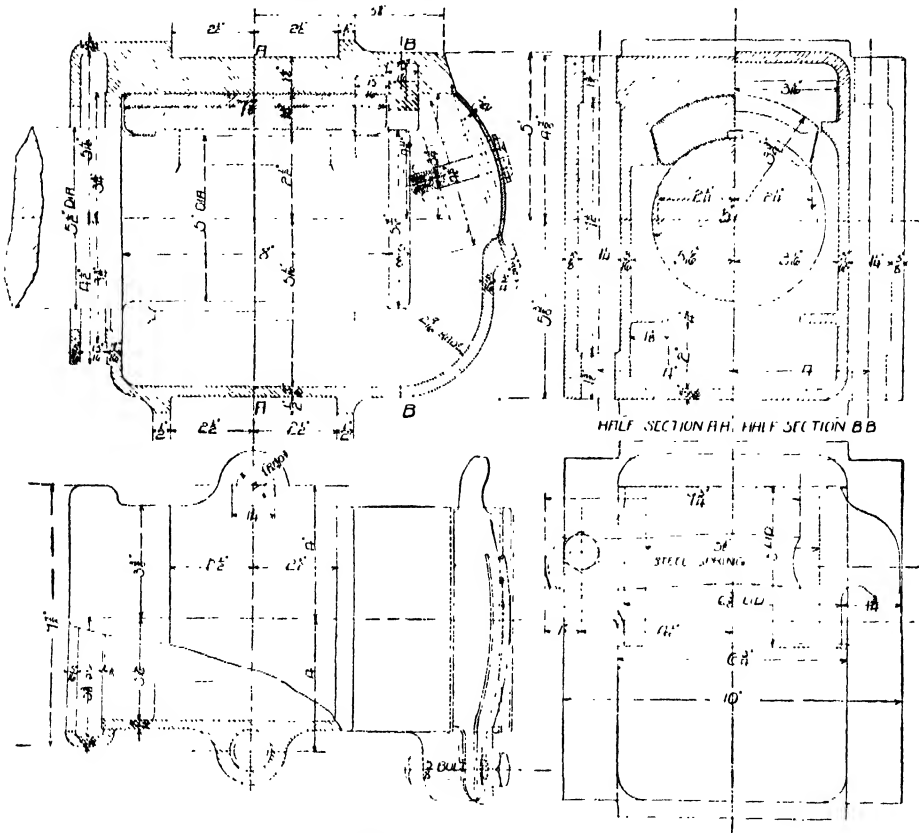

62. WAGGON AXLE-BOX

manner to the waggon box brass; the keep is formed by the circular hole in the inside end of the box, which prevents the axle being seriously displaced. The box is fitted into the

## DRAWING

steel frame of the bogie, and is held therein by two 1-in. diameter bolts, which pass through the whole depth of the box. The bearing is lubricated from beneath, the space below the journal being used as an oil bath, and the whole chamber up to the axle being filled with a mixture of cotton waste and horsehair. Sometimes a pad is placed under the axle and is supported in a light metal frame, and suitable feeding wicks are led into the oil bath. The door in the front end of the box is much larger than in the previous example in order to admit the pad, etc. The views given are generally similar

6½ in. diameter by 7½ in. long; the brass is a complete half-circle on the journal, but is bored out ⅜ in. clear of the axle on each side to allow for play; the keep is an iron casting held in place by two ⅛-in. pins; the box is guided by cast-iron guide bars strongly bolted to the steel frames of the locomotive; the rectangular bar with rounded end shown at the top of the box conveys the pressure to the spring. The upper part of the box is hollowed out to serve as an oil reservoir; two oil tubes are fitted as shown, and are fed by wicks led into them from the reservoir; a thin steel plate covers the top to

63. CARRIAGE AXLE-BOX

to 62, but an end elevation takes the place of the detail of the brass; this is done in order to show the door and its spring. It will be noticed that in the longitudinal section the hinge pin of the door is indicated by chain-dotted lines; this is a convention adopted in order to show a detail which, properly speaking, could not be seen, since it is on that portion of the box which is removed in order to show the sectional view.

**Locomotive Axle-box.** A locomotive axle-box is shown in 64. It will be seen that the construction differs slightly from the waggon box [62] and the carriage box [63], but that it is more compact and substantial; the journal is

keep out dust and dirt. Axle-boxes of this class are frequently fitted with oil pads in the hollow of the keep as an additional means of lubrication. The keep can be removed bodily for inspection of the pad.

**Babbitt Bearings.** Brass and bronze are not the only metals which are used for bearings; various fusible alloys are also available, but are used as linings only, a removable shell being employed to carry them. Fig. 65 illustrates a shell lined with Babbitt metal, which is an alloy of tin, copper, and antimony; the shell may be either of brass or of cast iron, with recesses as shown to prevent movement of the

65. BABBITT BEARING

lining ; this class of bearing is used to a greater extent in America than in England, and the example given [65] is a reproduction of an American working drawing. The shell is somewhat thinner than an ordinary brass bearing, and is machined all over to bear its full length in the pedestal or seating block ; it is prevented from turning by a peg or dowel fixed in the pedestal, and entering the lower half of the shell. The lining is readily renewed when worn away too much for the proper support of the journal. Babbitt and similar metals melt at a low temperature, and can be poured like type metal ; to renew a lining the old one is first melted out, then a dummy shaft or mandrel is placed in the shell, and new metal poured around it.

**Brackets and Hangers.** It is only in the building of a machine or engine that bearings are formed or fitted direct to framings, etc. For line shafting and for bearings on structural work it is usual to have a bracket between the bearing and its eventual support. Fig. 66 shows a plummer block fitted to a bracket, which has feet at right angles to the foot of the block, and is suitable for bolting to a wall or a column ; the block might be cast in one piece with the bracket, but when made separately, as shown, it is readily adjustable horizontally and vertically ; the bolt holes in the base of the pedestal are slotted, so that the block may be adjusted laterally ; hardwood or steel wedges are then driven in at the ends. If vertical adjustments be required, a liner may be placed between the base of the pedestal and the bracket.

Fig. 67 illustrates a hanger suitable for suspending a pedestal from a ceiling or roof girder ; the block is adjustable in the same manner as in the previous example. The

dimensions of 66 and 67 are found by multiplying the figures given on the drawings by  $A + \frac{1}{2}$  in. where  $A$  = diameter of shaft ; the overall dimensions are of course modified to the local conditions.

There are many bearings which may be classed as special, such as footstep bearings, thrust bearings, roller bearings, ball bearings, heavy crank shaft bearings, etc.

These are all dealt with in Machine Design.

**Belt Driving.** Belts are used for transmitting power from line shafting to machines by means of pulleys ; power may also be taken from an engine or a dynamo to shafting by belting and pulleys. Driving belts are usually made of leather, but other materials, such as camel hair, cotton, indiarubber, etc., are successfully employed, and in some situations are superior to leather, as they are less affected by damp, chemical fumes, etc. ; in the case of the camel-hair belting, there is less slip between the belt and the pulley, and consequently a better driving effect is obtained. Leather belts are made from the best portion of ox-hides. The amount that can be utilised from an average hide is about  $4\frac{1}{2}$  ft. long by 4 ft. wide, and is termed the "butt." The thickness is about  $\frac{3}{16}$  in. to  $\frac{1}{4}$  in. ; the ultimate strength of the prepared leather is about 3,500 lb. per square inch, but this cannot be taken full advantage of in a belt on account of the jointing which is

66. BRACKET AND PLUMMER BLOCK

**necessary. If** due allowance be made for the laced joint and for a reasonable margin of safety 350 lb. per square inch may be taken as a safe working load. In calculating the size of a belt for a particular duty it is more convenient to figure the load in lb. per inch of width of belt; 350 lb. per square inch is equal to 66 lb. per inch of width if the belt be  $\frac{1}{4}$  in. thick, or 78 lb. if the belt be  $\frac{1}{2}$  in. thick. Double belts are made by cementing two strips of leather together in a superimposed position; they are then sewn or riveted; the resulting thickness is  $\frac{3}{4}$  or  $\frac{1}{2}$  in., as the case may be. Such belts have not quite double the strength of single belts, nor do they and as they are not so strong on small pulleys; a 30-in. small enough for a dou-

**Speed and Power of Belting.** The speed of belting varies according to the work it is designed to do; lathes and machine tools have a belt speed of 1,000 to 2,000 ft. per minute, line shafting may go up to 2,500 ft. per minute, main drives from engines up to 4,000 ft. per minute; some belts run above this latter speed, but no material advantage is gained thereby. The speed of a belt is easily calculated from the diameter and speed of the pulley. The rule is: Multiply the diameter of the pulley by 3·1416, and by the number of revolutions per minute of the shaft. Example: A shaft revolves at 150 revolutions per minute, driven by a pulley 36 in. diameter, the speed of the driving belt is 36 by 3·1416 by 150 = 1414 ft. per minute. A slight inaccuracy, however, is here to be noticed; the speed calculated above is the theoretical speed of the rim of the pulley; now a belt "slips" to a certain extent upon the face of a pulley, and by that amount lags behind the speed of the pulley. The usual amount is 1 per cent., so that the actual belt speed in the case above figured out would probably be 1,400 ft. per minute.

Power is transmitted from a belt to a pulley or vice versa by frictional contact, and it therefore depends considerably upon the arc of circumference embraced; if the arc of contact be increased or decreased, so the grip of the belt upon the pulley is increased or decreased, and the driving effect varied accordingly. This is

## 67. HANGER AND PLUMMER BLOCK

very important to note when designing belt drives, since very inefficient drives result if the difference in diameter between two pulleys—driver and driven—be greater than 6 to 1. For instance: If a 6-ft. diameter pulley were set to drive one of 12 in. diameter, there would be scarcely any grip of the belt upon the smaller of the two unless they were placed a long way apart or some tightening device arranged.

**Tensions.** The tension in a belt is not the same on both sides of the drive, but the pulling or driving side has to sustain a load above the power transmitted equal to the frictional resistance to slipping on the surface of the pulley, and this must be taken into account when estimating the size of a belt. A good average ratio works out at 2 to 1—i.e., the driving side has to sustain twice the tension due to the power transmitted, upon which basis we may calculate the width of a belt as follows :

$$\frac{\text{horse-power} \times 33,000 \times 2}{\text{speed of belt in ft. per min.}}$$

Width of belt in inches  
maximum load in lb.  
75 lb. per inch of width

for single belt, and

maximum load in lb.  
140 lb. per inch of width

**for double belt.**

The ratio of the two tensions in a belt drive varies according to the coefficient of friction between the belt and pulley, and also upon the arc of contact.

# SOME PRODUCTS OF ALCOHOL

Chloroform, Glycerine, and other Alcoholic Derivatives.  
The Marvellous Work of Pasteur and its Results

By Dr. C. W. SALEEBY

WE have already said that the ketones are closely allied to the aldehydes. When a primary alcohol undergoes oxidation the product is an aldehyde; when a secondary alcohol undergoes oxidation the product is a ketone. There are several other ways in which the ketones may be produced. Their relation to the aldehydes is best shown by instancing the most important of the ketones. Thus, Sir William Ramsay says: "While aldehydes contain carbonyl, the group  $\text{CO}$ , in union with an alkyl radical and with hydrogen, ketones contain carbonyl in union with two alkyl radicals. This analogy is shown by the formulae:

**Acetone.** The substance the formula of which has just been stated is, without doubt, the anhydride of a dihydric alcohol. The reader should write the graphic formula and see this for himself. Its most common name is *acetone*, and it is usually produced by the action of heat on the acetate of calcium. It is a colourless mobile liquid which, as might be expected, is extremely inflammable. It is a useful solvent for a number of substances such as resins and camphor. It is the first of the ketones, of which a large number have been prepared. When ketones are oxidised they split up and yield a mixture of acids. This is as might have been expected, giving us two parallel results of oxidation, thus: primary alcohol, aldehyde, acid; secondary alcohol, ketone, acid.

There is no end to the complexities which are possible by reason of the existence of these various alcohols, aldehydes and ketones. Chemists are able to make atoms and groups of atoms, such as hydroxyl ( $\text{OH}$ ), carbonyl ( $\text{CO}$ ), and carboxyl ( $\text{COOH}$ ), change places with one another according to circumstances, and can introduce a whole series of other atoms such as those of the halogens. Space has availed us here merely to outline the subject and to consider one or two of the most important bodies out of a wholly indefinite number.

**Chloroform.** The famous and invaluable anæsthetic called chloroform should properly be called, as we already know, *trichloromethane*. It is simply methane, of which three atoms of hydrogen have been replaced by atoms of chlorine. It was independently discovered by various chemists in America, France, and Germany in the years 1831 and 1832. In 1834, its constitution was recognised by Dumas. It was in 1847 that Sir James Simpson introduced it as an anæsthetic into surgical practice. In a large number of cases in general surgery, in midwifery practice, and on the battlefield this compound has no rival as an anæsthetic.

**Characteristics of Chloroform.** It is a colourless, mobile, highly refractive liquid, the physical properties of which—such as its specific gravity—are of importance in relation to tests for its purity. It is liable to undergo change on exposure to light, and its manufacture is complicated by the occurrence of a large number of impurities, some of which may be highly dangerous when inhaled. Chloroform exposed to air and light yields, among other substances, chlorine and hydrochloric acid. It is of immense importance that chloroform, when used as an anæsthetic, should be as pure as possible, and therefore too much care cannot be spent upon its manufacture and the manner in which it is kept after manufacture. For instance, no surgeon should allow chloroform to be exposed to light if it is afterwards intended to be used for purposes of inhalation. This body is a valuable solvent for a large number of organic substances, such as resins, gutta-percha, alkaloids, etc. Its purity for purposes of this kind may also be important. Pure chloroform should yield no opalescence on admixture with water, and should not be coloured on the addition of sulphuric acid or chromic acid.

**Preparation of Chloroform.** There are many chemical processes which will yield chloroform. It may be obtained, as we have already noted, by the direct action of chlorine on marsh gas, or, on the other hand, the body which has the formula  $\text{CCl}_4$ , will yield chloroform under the influence of hydrogen so conditioned as to replace one of its chlorine atoms by an atom of hydrogen in each molecule. Chloroform is also formed by the action of alkalis upon chloral. This fact is of historical interest, for chloral was introduced into medicine by Liebreich under the impression that the alkaline blood would cause it to yield chloroform, in virtue of which it would exercise useful actions. As a matter of fact, chloral is not decomposed in the blood, and no trace of chloroform can be found anywhere after its administration; but a powerful alkali, such as caustic potash, easily produces chloroform by this decomposition. This method is fairly cheap, but that most commonly employed consists of the distillation of a mixture of bleaching powder and highly diluted ethyl alcohol. The somewhat complicated series of reactions cannot here detain us, but the extreme importance of the purity of chloroform used in medicine and surgery, and the very serious consequences which may follow upon its impurity in such cases, are worthy of reassertion in closing our discussion of this body.

**Allies of Chloroform.** If chlorine can replace hydrogen in methane, so, of course, can the other halogens. Thus, in strict correspondence to chloroform,  $\text{CHCl}_3$ , we have bromoform,  $\text{CHBr}_3$ , and iodoform,  $\text{CHI}_3$ . Bromoform was expected to be useful as an anæsthetic, since the bromides, such as potassium bromide, have a soothing action upon the nervous tissue; but the drug is too dangerous for employment. Iodoform, however, a yellow crystalline solid (to which we have already referred, since its production is a test for the presence of alcohol), is extremely useful in medicine, or rather in surgery, though its employment depends upon other chemical characters than those of chloroform, and is directed to different purposes. Iodoform (which, of course, should technically be called *tri-iodomethane*) is formed by heating together alcohol, iodine, and caustic potash with the production of potassium iodide, water, potassium formate and iodoform—which crystallises out in distinctive yellow crystals. These should be powdered before use.

Iodoform has a very characteristic odour; it is scarcely soluble at all in water or alcohol, but freely so in fixed and volatile oils, chloroform and ether. It contains nearly 97 per cent. of iodine by weight, as the reader will understand if he remembers that the atomic weight of iodine is 127, and that there are three atoms of this element in each molecule of iodoform. Free iodine is given off by iodoform at the quite low temperature of  $250^\circ \text{F}$ .

**Action of Iodoform.** The surgeons say most positively that iodoform is an extremely valuable antiseptic; the bacteriologists reply that, on the contrary, iodoform has no antiseptic properties at all, that bacteria can grow in it freely, and that if the surgeons use it they should sterilise it first, just as they sterilise anything else that has no antiseptic properties. Chemistry comes in and solves the incompatibility between these two sets of statements; and, as might be expected, the solution offered by chemistry has led to considerable improvement in the manner in which iodoform is used and to the obtaining of better results than ever from it. It is true that, as such, iodoform has no antiseptic properties; it is also true, on the other hand, that elementary iodine is an extremely powerful antiseptic.

When iodoform is used in surgery it is dissolved by the oily matter which is present everywhere in the body. When thus dissolved it is readily decomposed by many agents. Free oxygen, under the influence of light, decomposes it. Living protoplasm, aided by oxyhæmoglobin,  $\text{HbO}_2$ , decomposes it; so also do many of the poisonous organic substances which are produced by bacteria when they grow in the body. The consequence is the very slow but continuous production of iodine in the nascent state. The production being slow, there is no local irritation; the iodine being nascent, its chemical activity is very great indeed—in other words, it is more powerful an antiseptic than ever. Hence, we now have a complete explanation, in accurate chemical language,

of the invaluable properties of iodoform in surgery.

**A Trihydric Alcohol.** There is obviously no reason why we should stop at dihydric alcohols, any more than at the monohydric alcohols which were first considered. As a matter of fact there are trihydric alcohols. These again, like their predecessors, may be regarded as hydroxides or hydrates; and, like their predecessors, they may be dehydrated, yielding oxides or anhydrides. A large number of such bodies exist, and they may be divided into various groups according as each hydroxyl group is attached to a separate carbon atom, or two to one carbon atom and one to a second, or all three to the same carbon atom. Here, however, we shall discuss merely one trihydric alcohol; this belonging to the series in which each hydroxyl group is attached to a separate carbon atom. This alcohol should properly be known as *glycerol*, but that is not the most familiar form of the name, though it is good as suggesting the chemical character of the substance.

This trihydric alcohol is commonly spoken of as *glycerine*. It may be obtained in a number of different ways, but of these we need only mention the most practically important. These consist in utilising the action either of powerful alkalies, such as sodium hydrate, or of superheated steam upon fats or fixed oils. (The reader will remember that a fat and a fixed oil are chemically identical, differing only in being solid or liquid, respectively, at ordinary temperatures.)

**Properties of Glycerine.** The production of glycerine from a fat or fixed oil is of the greatest chemical interest as throwing light upon the nature of fats and upon various physiological and commercial processes. We discuss it in considering the fats in general; meanwhile we merely observe that this is the fashion in which glycerine is usually obtained, and that in order to endow it with the greatest purity it is distilled either with superheated steam or in a partial vacuum. If glycerine be distilled at the ordinary pressure of the atmosphere it undergoes decomposition.

The empirical formula of glycerine is usually written  $\text{C}_3\text{H}_7(\text{OH})_3$ . This expresses well enough the relationship of this trihydric alcohol to propane,  $\text{C}_3\text{H}_8$ . Plainly, three hydrogen atoms of propane have been replaced by three hydroxyl groups to form glycerine. Also, if we call  $\text{C}_3\text{H}_7$  *glyceryl*, glycerine is the *hydrate of glyceryl*. The physical characters of glycerine are familiar to everybody. It mixes readily with water and alcohol. Its affinity for water is extremely powerful, and glycerine as we know it is always associated with some water, in this respect resembling a much more familiar alcohol. Under certain conditions—cooling and shaking—it can be made to freeze, and if a crystal of glycerine be then placed in liquid glycerine at a temperature of  $0^\circ \text{C}$ , it causes that liquid specimen to freeze also. As we might, of course, expect, glycerine, like any other alcohol, yields an acid on oxidation. This is known as *glyceric acid*.

**Glycerine and Sugar.** We all know the sweet taste of glycerine, a character so prominent that it has given the substance its name (Greek *glukeros*, sweet). We may compare the name of a typical sugar, glucose. Now, sugar is a valuable food, and the sweet taste of glycerine has suggested that it also may have a food value. Plainly, it has great potentialities of oxidation. But, as a matter of fact, glycerine undergoes either no oxidation at all, or no appreciable oxidation, within the body. It has, therefore, no food value. This circumstance explains the fact that glycerine has been found to fail completely when employed as a substitute for cod-liver oil in medicine. It has many uses, however. It is an excellent solvent for a number of substances; it does not evaporate; its affinity for water is of great value in preventing undue dryness of any part of the skin, and it is this hygroscopic property which makes glycerine so useful in the treatment of, for instance, chapped hands. It is definitely antiseptic. In virtue of its physical properties, also, it facilitates the absorption by the skin of various bodies which may be dissolved in it.

Besides its use in medicine, glycerine is used in many manufactures, and notably as the starting point for the production of many high explosives.

**Nitro-glycerine.** The common name for the product of glycerine which has explosive properties is nitro-glycerine, but this name is misleading. Nitro-glycerine was first discovered close on sixty years ago. The possibilities of this substance were later recognised by the late Mr. Nobel, whose name will always be remembered by the Nobel prizes which are awarded every year for pre-eminent services to science, literature, and the cause of peace. The reason why the name nitro-glycerine is incorrect is that in organic chemistry the term *nitro* is very precisely used to indicate bodies in which the nitro group,  $\text{NO}_2$ , occurs in direct combination with a carbon atom. On this definition the nitro compounds do not include nitro-glycerine, which is really a salt formed by the union of glycerine and nitric acid. The three hydroxyl groups of the glycerine have been replaced by the group  $\text{NO}_3$  of the nitric acid, so that this body is really a trinitrate of glyceryl.

The manufacture of this powerful body is a process of difficulty and danger. It consists essentially of mixing glycerine with nitric and sulphuric acid, thus, indeed, being the original process by which the compound was discovered in 1847. Usually the glycerine is injected into a mixture of the two acids, which are contained in lead tanks that have their temperature carefully kept low. The nitro-glycerine is immediately formed, and, as might be expected, much heat is liberated in the process. This heat, of course, must not be allowed to accumulate, or there will be a disaster. The reader will ask what the sulphuric acid accomplishes in this process. It undergoes no change, and has merely the function of absorbing the water which is produced by the decomposition. The reader should write out for himself the equation representing the change. He will find

that three molecules of nitric acid and one of glycerine will yield a molecule of the nitrate and three molecules of water.

**Properties of Nitro-glycerine.** Various purifying processes have to be employed in order to free the nitro-glycerine from any acids. The substance so obtained is a heavy, oily liquid, the freezing point of which is  $8^\circ \text{C}$ . When pure, it is quite colourless. It readily dissolves in ether, but scarcely at all in water. It has a rather pleasant and very marked taste. If a light be put to it it burns quietly, but if its temperature be raised to as much as  $240^\circ \text{C}$ , or if it be struck, or if even a little cartridge be exploded in contact with it, it explodes. Our study of gunpowder in a previous section has familiarised the reader with the meaning of any explosion, which is none other than a chemical decomposition involving the rapid production of a large quantity of hot gas. In order to see what the products of decomposition are in this case, we may write an equation. For this purpose it would suffice to take two molecules of nitro-glycerine, but we should find that this would leave us with an odd atom of oxygen on the other side of the equation. Now, we learnt long ago that O is merely a symbol for oxygen, and is not a proper expression for oxygen gas, the molecules of which consist of pairs of atoms. We must therefore employ four molecules of nitro-glycerine in order to write our equation, which will then run as follows:

Thus the consequence of the decomposition is the instantaneous production of four gaseous bodies, the temperature of which is that caused by the explosion. It is calculated that one litre of nitro-glycerine exploded will yield more than 10,000 litres consisting of a mixture of these gases. Hence the tremendous explosive force of this compound, which is nine or ten times as powerful as old-fashioned gunpowder.

**Dynamite.** Various devices have been adopted in order to reduce the grave danger which attends the manipulation of nitro-glycerine. The most familiar of these is the use of a substance called kieselguhr. This consists of the shells of minute animal organisms long dead. They are known as diatoms, and their remains consist mainly of silica.

Twenty-five per cent. of kieselguhr and 75 per cent. of nitro-glycerine forms kieselguhr *dynamite*, which, though by no means free from danger, gives rise to fewer accidents than nitro-glycerine itself. This is not the place in which to discuss the many other modifications of this principle—that of absorbing the nitro-glycerine in some non-explosive body. On the other hand, for some purposes the nitro-glycerine may be absorbed by substances which are themselves explosive.

**Nitro-glycerine and Physiology.** Nitro-glycerine is perhaps the last substance in the world which one would think of swallowing, but the preceding paragraphs will have made it plain to the reader that it explodes only under certain conditions, and that these

are incapable of realisation within the human body. As a matter of fact, nitro-glycerine has a very useful employment in medicine, in which it is employed in doses of about one-hundredth of a grain. This quantity is often made up in a tablet of chocolate, with which the risk of explosion is reduced to a minimum. There is no risk, of course, after the tablet has been swallowed, but only before. The actions of nitro-glycerine upon the body are those typical of a nitrite, the most marked consequence of its administration being a dilatation of the blood-vessels and a relaxation of spasm in any muscular tissue. It is a noteworthy fact that all nitrites have this property in varying degree; some day it will doubtless be capable of a simple chemical explanation in terms of the chemistry of muscular contraction, of which we know something already. Nitro-glycerine, however, is not a nitrite but a nitrate, and the question has to be asked why it should act as if it were a nitrite. Now, we find that if nitro-glycerine be subjected to the action of a mild alkali at the temperature of the body, about two-thirds of it is converted into a nitrite. That is what happens in the blood by a gradual process of reduction, hence the "nitrite action" of this substance and hence also the gradual onset of its action and the considerable period during which the action of a single dose persists. When nitro-glycerine is administered, one is really giving a substance which causes the gradual and continuous production of a nitrite in the blood.

We shall say no more about glycerine or its products at present, but merely ask the reader to recall our statement as to the manner in which it is usually manufactured, and to keep it in mind until we come to discuss the fats.

**The Trihydric Alcohols.** One other statement needs to be made about the trihydric alcohols, or, rather, about that group of trihydric alcohols in which all three hydroxyl groups are attached to the same carbon atom. It is that, rather paradoxically, the anhydrides of these alcohols are acids. If, for instance, we take the (imaginary) trihydric alcohol derived from methane, we shall have a body consisting of a central carbon atom, one hand of which is still occupied with a hydrogen atom, while the other three are attached respectively to the three oxygen atoms of three hydroxyl groups. The reader should write for himself this obvious graphic formula. If, then, he cuts out from it two atoms of hydrogen and one of oxygen so as to form the anhydride, he will find left a body which may be represented thus:

**Carboxyl.** The group which constitutes the greater part of the above formula has already been referred to under the name of carboxyl. It is characteristic of all the acids of carbon. If, for instance, we write the formula of acetic acid, which follows upon formic acid in the series we have already studied, we shall find it necessary merely to add  $\text{CH}_3$ —which is the difference between successive paraffins—to the above

graphic formula of formic acid, which would then have this appearance:

The reader should make a point of memorising the appearance of the carboxyl group in the above graphic formulae. He will see that the carbon of it has three of its four hands occupied with oxygen, two completely saturating the valency of one oxygen atom, while the third saturates the half-saturated oxygen atom of the hydroxyl group. The carbon atom then has a fourth hand left, which may give rise to almost endless complexities. But wherever we find an organic acid, or, rather, an acid of carbon, we shall find the carboxyl group.

The most instructive of these acids have already been studied—formic acid and acetic acid. The next on the list must necessarily have the formula  $\text{C}_3\text{H}_7\text{COOH}$ ; it is known as *propionic acid* and is very similar to acetic acid. Later we must discuss an important derivative of it. But the next is worthy of separate mention.

**Butyric Acid.** Continuing to write the formulae on the same plan, we must call that of butyric acid  $\text{C}_4\text{H}_9\text{COOH}$ . This may be obtained from butyl alcohol, but it is most commonly known as a characteristic product of the fermentation of sugar under certain conditions. The ferment is again a living body, and it occurs almost everywhere. The subject is one of some importance, practically, and we shall quote the chief facts from the best statement of them, which is to be found in the "Bacteriology of Milk," Swithinbank and Newman (John Murray, 1903). As long ago as 1840 it was discovered that butyric acid can be produced by fermentation. In 1860, the immortal Pasteur turned his attention to the subject, and, as in the case of every subject to which he devoted himself, transformed it by his genius. The puzzle was that sometimes, when sugar is being converted into lactic acid by means of lactic fermentation—to be studied later—the usual result is not produced, but instead the products are *butyric acid* and *hydrogen*. Pasteur showed that "two successive processes are here involved—first, the conversion of sugar into lactic acid as calcium lactate, and afterwards the transformation of the lactate into butyrate. He demonstrated that each of these changes is due to a special ferment—in the first place the lactic ferment, in the second place the butyric ferment."

**Microbes Killed by Air.** Pasteur found that whenever his lactic fermentations proceeded improperly, butyric acid and hydrogen being produced, there was a separate kind of microbe present. He subsequently discovered that if he examined under the microscope a drop of butyric fermenting fluid, "the organisms at the edge of the drop were motionless and apparently dead, while in the central portion of the drop the bacilli were executing those active movements which are characteristic of their vitality. To Pasteur's mind this at once suggested what he was able later to demonstrate—namely, that these organisms at the periphery were paralysed by contact with the oxygen of the air. When

he passed a stream of air through a flask containing a liquid in butyric fermentation, he observed that the process slackened and eventually ceased. "Those infusory animalculæ," he wrote, "live and multiply indefinitely, without requiring the least quantity of air. And not only do they live without air, but air actually kills them. It was sufficient to send a current of atmospheric air during an hour or two through the liquor where these vibriones were multiplying to cause them all to perish, and thus arrest the butyric fermentation, while a current of pure carbonic acid gas passing through the same liquor hindered them in no way. Thence this double proposition—the butyric ferment is an infusory; that an infusory lives without free oxygen."

Here, briefly stated, is the historic discovery of the *anaerobic* microbes—those which cannot grow in the presence of free oxygen.

The following are the chemical formulæ of the butyric reaction from the first:

and also

thereafter

Occasionally, butyric fermentation occurs in the stomach, and the hydrogen can be lit on emerging from the mouth.

**An Immortal Frenchman.** We may here interrupt ourselves in order to pay homage to one of the most illustrious names in the whole history of science. Though we think of Pasteur as a bacteriologist, he nevertheless was really a chemist. It was his great predecessor, Dumas, who led him to original research in chemistry, and the first piece of work which he accomplished made an epoch. He set himself to study the known fact of the existence of two tartaric acids, identical in every way except that one had no action on a ray of polarised light [see *Physics*], while the other turned the plane of such light to the right, or, as we say, was dextro-rotatory. Having set himself to this, Pasteur discovered that the acid which has no action upon polarised light is really composed of two isomers—one, the dextro-rotatory acid, already known, and the other a new acid, similar in every respect save that it rotated the ray to the left or was *levo-rotatory*, thus neutralising the action of its partner.

**Pasteur and Lister.** Pasteur's next great discovery was to show that a particular form of fungus, now famous, has a selective action upon the mixture of the two kinds of tartaric acid, destroying the right-handed acid alone, and so enabling him to obtain the left-handed one by itself. He then turned to the disorders of beer and wine, and founded the modern science of brewing—which depends, of course, upon a union of chemical and botanical knowledge. He showed, also, that all fermentation ceased—such as vinous

or alcoholic, acetous, lactic, butyric fermentations—when precautions were taken to exclude all living things. This discovery led to the work of our own Lord Lister, and to the establishment of modern surgery. At this point, as we see, Pasteur was beginning to leave chemistry—as the boundaries of that science were conceived in his time and by the great majority to-day—and was turning to the new science which all subsequent historians will date from him. His chemical friends and seniors advised him to stick to chemistry. He was wasting his time, they said, by studying these tiny microbes which one could scarcely see and which could never conceivably be of the smallest importance. Pasteur knew better, however, and he went steadily on.

**The Cash Value of a Scientist.** The silkworms in the South of France were dying of a strange epidemic disease, which had thus ruined the silk industry. Pasteur's advice was asked, and in three months he solved the problem. By a series of magnificently conceived researches he had found the cause of the disease and prevented its recurrence. This research alone would have been quite sufficient to give him a permanent place in the history of science, but it is a drop in the ocean of his achievements. Working on the principle of vaccination, the great French chemist set himself to produce complex chemical bodies of a specific character for each of the various diseases by utilising the microbes which caused these diseases. From the silkworm he turned to the fowl, and reduced to one-tenth of its former extent the death-rate from fowl cholera which at that time was destroying one in ten of all French fowls; he then turned to the terrible disease *anthrax* and similarly reduced from ten to less than one per cent. the mortality of sheep and oxen from this disease. Huxley estimated that the monetary value of Pasteur's discoveries to France was sufficient to cover the whole cost of the war indemnity paid by France to Germany in 1870. Pasteur then turned to the diseases of man, and discovered means by which he was able to control rabies, or hydrophobia, first of all in the dog, and then in man himself. This treatment was begun in 1885. Since that date the percentage of successes has steadily increased, until now it can be positively said that, given fair conditions, Pasteur's treatment will invariably conquer hydrophobia—except, as Prof. Metchnikoff has found, in alcoholic patients.

**"Everything is a Miracle."** Since then, the work begun by Pasteur has been followed up by a host of observers, who have carried his method of treating and curing disease to a distance which even he could scarcely have foreseen. He died in 1895. Pasteur was a devout Roman Catholic. In this respect he is unique amongst men of science of the first order for many centuries past. Among his noteworthy sayings we may quote the fine pronouncement of this consummate student of Nature upon the question of miraculous happenings. He said: "Tout est miracle" (Everything is a miracle).

Continued from  
page 3161

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

**A**FRICA (11,500,000 sq. miles) is a peninsula, almost separated from the rest of the Old World, to which it is united only by the narrow Isthmus of Suez. At two points, however, its shores almost touch the other Old World continents—in the north-west, at the Strait of Gibraltar between Morocco and Spain, and in the north-east, at the Strait of Babel-Mandeb between Eritrea and Arabia. Evidently, therefore, much of northern Africa must closely resemble regions already described.

**Position, Shape, and Coastline.** Africa lies between lat. 37 N. and lat. 34 S., so that it is roughly bisected by the equator. Owing to the shape of the continent, more land lies in the Northern than in the Southern Hemisphere. The northern shores are washed by the Mediterranean, the western by the Atlantic, and the eastern by the Indian Ocean. Its southern apex is at the junction of these two oceans. The continent has none of the peninsulas and gulfs which cut up the sister continents. Consequently, in spite of its vastly greater area, its coastline is less than that of Europe.

**Islands.** There are few islands in African waters. In the Atlantic are Madeira, the Canary and Cape Verde Islands, at no great distance from the north-west coast, with Ascension and St. Helena in the South Atlantic at a much greater distance. In the Indian Ocean are Madagascar, with Mauritius and Réunion to the east, and Zanzibar, Socotra, the Seychelles and other smaller islands to the north.

**Highlands and Lowlands.** A relief map of Africa at once shows how few and small are the lowlands. They are confined to the coast, the river valleys, and isolated parts of the desert of North Africa. The coastal lowlands are narrow, except along the Mediterranean and in Senegambia, the extreme western part of the continent. The rest of Africa is over 600 ft. above the sea, forming a great plateau, or series of plateaux, rising in the Abyssinian plateau to 15,000 ft. in the north-east, in Ruwenzori in the east to 18,000 ft., and in the southern plateau to 11,000 ft. Mountain ranges like those of Europe or Asia are confined to the Atlas of North Africa (14,000 ft.), which is separated by depressions to the south and east from the other highlands of Africa, and is really continuous with the Sierra Nevada of Southern Spain and the Apennines of Sicily and Southern Italy.

**The Rift Valleys of Africa.** The highest parts of the plateau are isolated peaks in the east, where the old volcanoes Kenia and Kilimanjaro rise to 17,000 ft. or 19,000 ft., round two great rifts in the earth's crust, running north and south. These rifts are partly filled by a chain

of long, narrow lakes. The western rift contains Lakes Albert Nyanza and Albert Edward Nyanza in the Nile basin, Tanganyika in the Congo basin, and Nyasa in the Zambesi basin, with some smaller ones. Above this western rift, south of Albert Edward Nyanza, rises a group of active and extinct volcanoes about half as big as Mont Blanc. Of the lakes in the eastern rift the largest is Lake Rudolf. This interesting region is often called the Plateau of the Great Lakes. In the east it is continuous with the southern plateau, the south-eastern margin of which forms the Drakenberg Mountains (11,000 ft.).

**The Rivers of Africa.** From the Plateau of the Great Lakes flow three great rivers: (1) the Nile, formed by the union of a tributary draining Lakes Albert Edward Nyanza and Albert Nyanza, and the main stream from Lake Victoria Nyanza, which fills a hollow as large as Scotland in the eastern plateau, and receiving on its way to the Mediterranean important tributaries from the Abyssinian highlands; (2) the Congo, which carries the waters of Tanganyika and smaller lakes west to the Atlantic, receiving on the right bank tributaries from the lake plateau which have risen close to the Nile, and on the left bank tributaries from the northern margin of the southern plateau; (3) the Loangwa tributary of the Zambesi, which rises quite near the Congo, though the main stream of the Zambesi rises in the southern plateau, near the left bank tributaries of the Congo. Very short canals would, if practicable, unite by water the mouths of the Congo and Zambesi with each other, and both with the Mediterranean.

The rest of the southern plateau is drained by the Limpopo, flowing east to the Indian Ocean, and the Orange, flowing west to the Atlantic, as well as by other rivers which lose themselves in the desert portion of the plateau.

The north-western half of the continent is markedly lower, and little of the land between the Atlas and the northern margin of the southern plateau is over 3,000 ft. high. The only great river is the Niger, which carries the heavy rains of North Equatorial Africa to the Gulf of Guinea. It rises in the Futa Jallon highlands south of Senegambia, near the Senegal, which flows west to the Atlantic. A great part of north-west Africa forms a basin of inland drainage.

**Climate.** As Africa is bisected by the equator the climate of the two halves, allowing for differences of configuration, will be generally similar. We must not forget, however, that the seasons of the north and south are reversed. It is summer in North Africa in June when it is midwinter in South Africa, and midsummer in the latter in December

The tropic of Cancer crosses North Africa, and the tropic of Capricorn crosses South Africa. The whole continent, therefore, is in the warm belt, and most of it is intertropical. Except in the extreme north and south, the winter temperature is never below 60°, except at a considerable elevation. That is, the winters of most of Africa are as hot, or hotter, than our summers. In July the highest temperature occurs in the centre of North Africa, where the sun is nearly vertical at noon. This region is a desert, and as there is no screen of cloud to intercept the sun's rays, and no screen of vegetation to prevent a great heating of the earth's surface, very high temperatures are recorded. The same region has a great range of temperature, for, owing to the same causes, heat is rapidly lost by radiation when the sun moves south. In South Africa the hottest region in January is in the interior, a little north of the tropic of Capricorn.

**Rainfall of Africa.** We know enough now of the distribution of rainfall to forecast the conditions in Africa. Round the equator there is a very rainy region, with rain at all seasons, but especially in spring and autumn, when the sun crosses the equator. As, however, we recede from this region the dry and wet seasons become more marked, rain falling only in summer. Still further we gradually pass into the trade-wind area, the summer rains steadily diminish, and the climate becomes drier and drier, till over large areas it is entirely rainless. Still receding, we find the extreme north and south within the area of winter rains, the characteristic of the Mediterranean climate. These general features are found on both sides of the equator, in the centre and along the west coast, with some modifications, which need hardly be considered here, caused by the different atmospheric conditions due to the preponderance of land in North Africa, and of sea south of the equator. In the south-east, however, where the south-east trade wind is forced upwards by the rising land, rain falls in latitudes which are desert in the west. In the north-east there is practically continuity of land and of desert conditions.

**Zones of Vegetation.** We also know which of the characteristic zones of vegetation to expect. Neither tundra nor cool temperate forest will be found, and the steppe only in a very limited form. What we shall expect to find well developed is the desert in the rainless areas, and the characteristic savanas and forests of the tropical and equatorial regions.

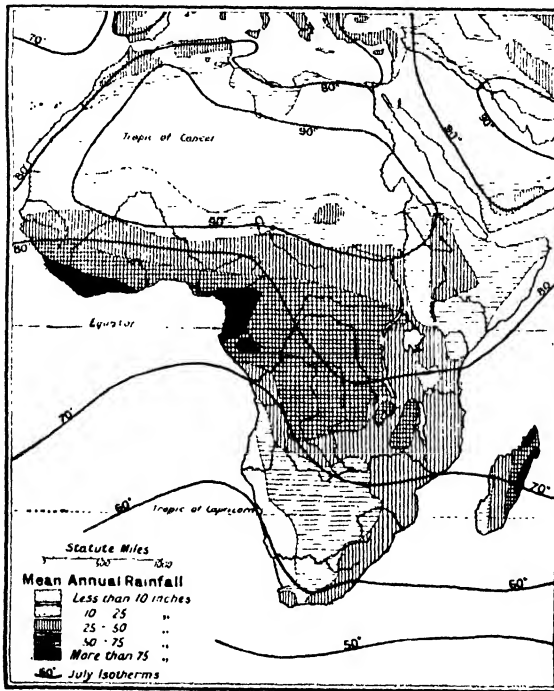

Owing to the much greater extension of land in North Africa, the Sahara, the northern desert, is far greater in extent and more arid in character than the Kalahari desert of South Africa. The savanas, or grass lands, with open woods, are better seen in Africa than in any other continent, not excepting South America, where they are also well developed. The equatorial forests of the Congo are inferior only to those of South America,

where the equator crosses the continent at its broadest.

**Plants.** In Mediterranean North Africa we find, among plants [125], the evergreen oak, the date palm, the olive, the vine and fig, the maize, millet, and rice, of other Mediterranean lands. This vegetation enriches the oases, of which Egypt is the largest. In the steppe regions of North Africa large tracts in Algeria and Tunis are covered with halfa grass. Except on the margin and in the oases the desert has little vegetation, and that of a thorny type, gum acacias predominating. New palms appear in the savanas,

and the banana becomes an important food tree. The massive baobab gives a new aspect to the landscape. In the forests of West Africa the oil and wine palm are both valuable trees. The equatorial forests have a flora too varied for description. About the deltas of tropical African rivers are mangrove swamps, round whose contorted, stilt-like roots, the new land steadily grows.

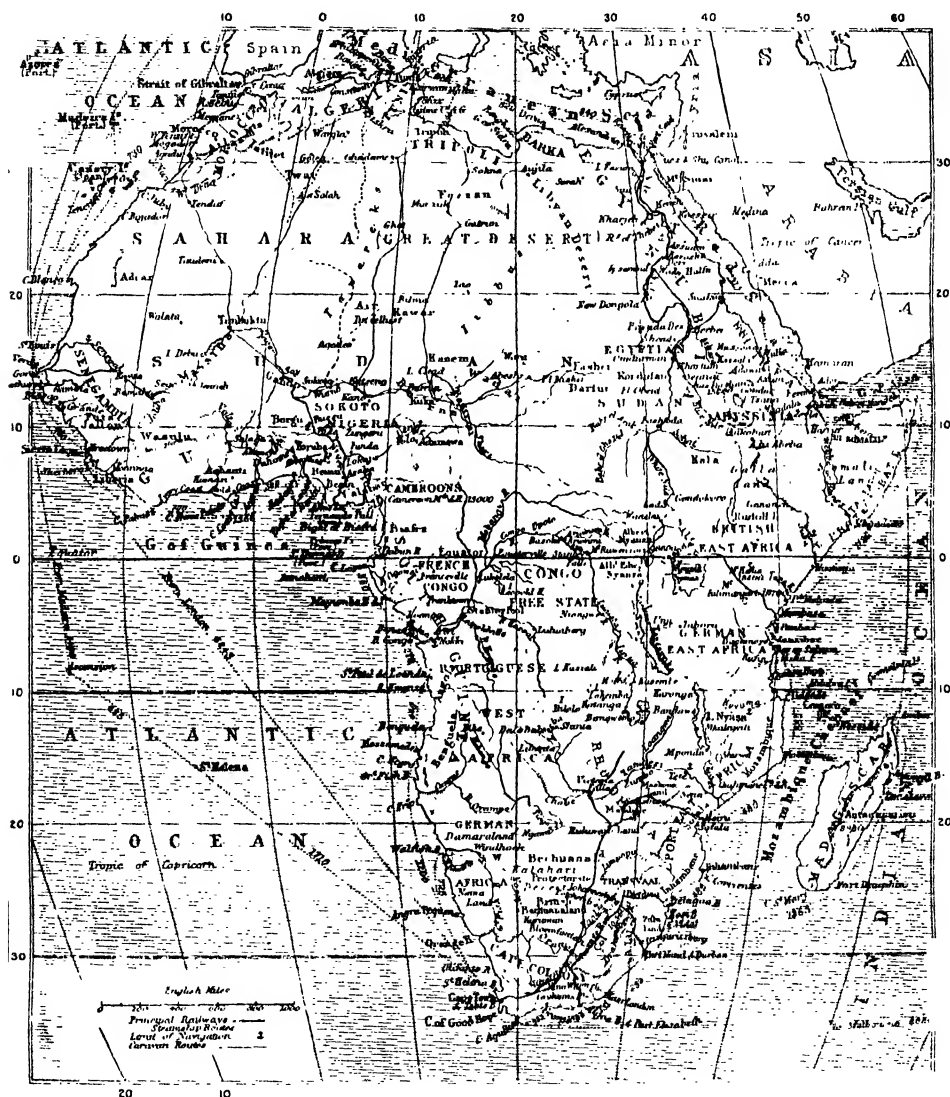

The cereals are wheat in the Mediterranean region, with rice and maize in the swamper and hotter parts respectively. Maize and wheat are also the cereals of South Africa. In the savanas millet, dhurra, and other grains are grown, as well as maize. Cotton, sugar, and indigo are cultivated in the Nile basin. Cotton

123. CLIMATE AND RAINFALL OF AFRICA

is an important crop in the Niger basin. Coffee is increasingly grown on the highlands of the savana region, and tea in parts of south-east Africa; and in the south all Mediterranean products can be raised. The characteristic vegetation of South West Africa consists of heaths and other beautiful flowering plants.

for size and beauty. Of the beasts of prey, the largest are the lion, panther, leopard, and hyena. Of animals not carnivorous, there are the elephant, the hippopotamus, which makes its home in the reedy river banks, the tall giraffe, the rhinoceros, the zebra, the gnu, and innumerable antelopes, buffaloes, apes—

124. THE CONTINENT OF AFRICA

**Animals.** In the Mediterranean region the usual Mediterranean animals are found. The camel is indispensable in the desert. In South Africa the domesticated animals are those of Europe, oxen and mules being used for draught. In the savanas are found innumerable wild animals equally remarkable

large and small—besides others too numerous to mention. Of birds there is the great ostrich, bred for its feathers, and also wild. Reptiles and insects are numerous and formidable. The tse-tse fly bites cattle and horses, and thus interferes with free settlement. Locusts do continual damage in many parts of the country.

**Political Condition.** Until a generation ago Africa was mainly a black man's country, but though the population is still overwhelmingly non-European, European interests now predominate everywhere. Africa differs from Europe and Asia in having developed few strong native powers. For this the character of the country is no doubt partly responsible. In the desert, for example, combination, except on a small scale, is almost impossible; the same is true of the forest area. Elsewhere in the rich savanna regions the very fertility of the country has been against organisation, by making life fairly easy for individuals. Outside the Mediterranean, the Nile basin, and the Sudan, the country was and is ruled by petty chiefs of only local importance. This has made it easy for Europeans to obtain control of the country outside the areas with some definite political organisation.

Britain administers Egypt (nominally Turkish) and the Nile Sudan, Nigeria and other parts of the Guinea Coast, British East Africa on the plateau of the Great Lakes, and a vast South African territory stretching from Lake Tanganyika to the Cape. A compact French territory includes Algeria, much of the Sahara, the Eastern Nigerian and Central Sudan, and as far south as the north bank

of the Congo. Madagascar is also French. Germany has secured parts of the west coast, South-west Africa, and the country between Lakes Tanganyika and Victoria Nyanza on the Red Sea coast. Portugal has territories both on the west and east coasts of South Africa. Italy has planted colonies on the east coast and also south of Somaliland, the eastern horn of Africa. Spain has a small territory on the north-west coast in the Gulf of Guinea. The Congo independent state, commonly known as the Congo Free State, is controlled by Belgium.

**Occupations.** In the Mediterranean region agriculture is possible. Here we find organised states, settled cities, and various industries and handicrafts. The same is broadly true of the desert oases. In the desert proper agriculture is impossible. The inhabitants depend on their camels and other animals, which pick up a living on the scanty vegetation. Their

owners are a nomadic race, who strike their tents and move to new pastures as occasion requires. Thanks to the camel, communication is possible across the desert, and well-defined routes go from oasis to oasis.

The Sudan, or the Country of the Blacks, the land between the forest zone and the Sahara, including much of the Nile and Niger basins, has agriculture, settled cities, some political cohesion under petty rulers, and important commercial relations.

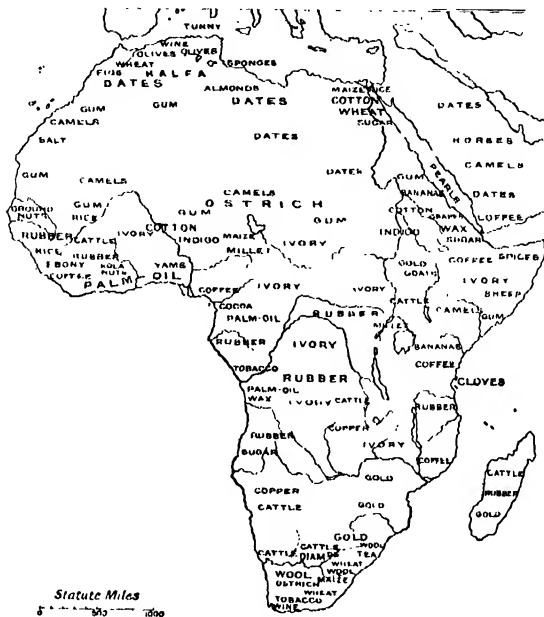

**Central Africa and the Forest Region.** In the savanas both agriculture and cattle-keeping are possible, and one or other predominates according to locality. Many tribes have useful arts and handicrafts, but they live

in a state of constant war, which prevents progress in the arts of peace. Over most of Central Africa the villages are surrounded by defensive stockades and trenches, and are built of perishable materials, so that they can easily be reconstructed.

In the forest we find tribes at a very low level, ignorant of agriculture, the keeping of animals, and the arts. They live by hunting and barter. Many are of dwarfish stature, and are called pygmies. Little higher in the scale are the Bushmen of South Africa, now rapidly disappearing, who live by hunting

and gathering wild products. Wherever Europeans come they introduce peace at the sword's point, build cities, develop the existing resources of the country, and add to them by introducing new plants, animals, methods of cultivation and industries. Great hardships are often inflicted on the inhabitants during the period of transition. The substitution of mining for pastoral interests in the Transvaal was not accomplished without a war, in which the clash of economic interests was as evident as the race antagonism.

**The Slave Trade.** For many centuries the slave trade has been the curse of Africa. The progress of civilisation is bound up with the making of good roads. The natural conditions of Africa are so unsuited for easy movement that without a strong government, effective over wide areas, roads could neither be made nor maintained. Where each tribe is the enemy

## 125. THE PRODUCTS OF AFRICA

of its neighbour it is obviously bad policy to make roads which render attack easy. This absence of roads is largely responsible for the slave trade. Human carriers were the only possible means of transporting merchandise, and this expensive method could only pay if carrier as well as merchandise were sold at the journey's end. The feuds of tribe and tribe made it easy for traders to arrange for slave raids, by which the required number of slaves was provided. The Transatlantic slave trade under European auspices has been suppressed, but as a domestic institution slavery is by no means stamped out.

**Religions.** The religion of a people is an index to its place in the scale of civilisation. Only two religions are associated with the more civilised African peoples—Christianity and Mohammedanism. The former is the religion of the European. A debased form is professed in Abyssinia. Mohammedanism is the creed of the Mediterranean region, the desert, and the Sudan. The savana and forest peoples have various pagan cults, often associated with human sacrifices and other revolting practices. The lowest tribes are sometimes said to be without religious ideas of any kind.

**Races.** The problems concerning African races are unsettled. Broadly speaking, the white race does not extend south of the desert, and within this area has a considerable admixture of other blood. The peoples of the savanas and tropical forests are mainly of negro origin, with a strain of white blood in the north-east. The Hausas and Fulas of West Africa are the most civilised of the Sudan peoples. The dwarf Pygmies of the equatorial forest are probably a primitive people, perhaps related to the Bushmen of South Africa. In the extreme south are found Bushmen and Hottentots, who are neither whites nor negroes. There is a sprinkling of European settlers, chiefly in the extreme north and south. Malay, Indian, and Chinese labourers have been introduced.

**Morocco.** Morocco (170,000 sq. miles without desert) consists of the well-watered

fertile north-west, the Atlas region, and the desert beyond, with its oases. The population of Morocco is nomadic or settled according to the pastoral or agricultural character of the country. The inhabitants of the lower plains are chiefly Arabs. The Berbers are a hill people, engaged in agriculture, and building fortified villages on the heights. The country produces all Mediterranean products, but is backward in developing its resources.

**Scenery in Morocco.** Travellers in Morocco usually make for one of the three capitals, Mequinez and Fez in the basin of the Sebu, the largest river, and Morocco, in the Tensift basin. A traveller's description brings Northern Morocco clearly before us. "The

entire day was spent in marching through one plain and over a range of round, smooth hills, into another. These plains showed extremely fertile land for grain and rich meadows for cattle. Occasionally we would cross a green valley with a small stream flowing through it. The contrast between its rich green — often it came from a grove of orange trees — and the surrounding brown aridness was very striking. The prominent feature of the country was its treelessness. Here and there, but at long distances, one saw small groups of olive or cork trees, or possibly an or-

chard. The few villages we encountered were surrounded by enormous fences of prickly pear cactus, an impenetrable mass 20 ft. in height, and as much in breadth." The towns are walled, the houses white for coolness, and the streets narrow. The distant view of the city is beautified by slender palms and minarets rising against the cloudless blue sky.

The ports are Tangier on the Strait of Gibraltar, and Mogador on the Atlantic, the port for Morocco city.

**Algeria.** Algeria (185,000 sq. miles without desert) consists of the hilly fertile Tell valley, parallel to the coast, above which rises the Tell Atlas, sinking in the south to a less fertile plateau, with shots or salt lakes, bordered on the south by the Saharan Atlas. The population

126. RACES AND RELIGIONS OF AFRICA

consists of Arabs and Berbers, with an admixture of French and other Southern Europeans. The country is developing rapidly under French rule, and much attention is paid to the vine by Europeans, while the natives raise cereals and animals. The absence of large rivers and the scanty rainfall in summer makes irrigation necessary.

The coast towns of Algeria are Oran, Algiers, Bougie, Philippeville and Bona. The chief inland centre is Constantine, on a commanding height, surrounded by a profound ravine. It is connected by rail with Biskra on the southern slope of the mountains, facing the Sahara, an oasis densely planted with date palms.

**Algerian Scenery.** A traveller from Algiers to Bougie writes: "We travelled through a hilly region. The soil seemed very fertile, and fig and olive trees and vineyards disputed the surface between them. Everywhere the Australian eucalyptus has been introduced on a large scale. We followed the course of a small river, shallow now, but its great bare rocky bed showed what it was in times of heavy rain. The cliffs of its gorge were very steep, and the railway was cut along one side and the highway along the other. The great grey rocks, the brawling stream, little Kabyle villages of stone huts with grass roofs, perched aloft in the shallow valleys, the occasional luxuriant vegetation, and the windings of the line gave this section of the railway very great interest. From now, on to Bougie, we went through a mountainous and diversified country very different from the plains crossed in coming from Oran to Algiers."

**Tunis.** Tunis (38,500 sq. miles without desert) is a French protectorate, divided into the same natural zones as Algiers. The capital, Tunis, is the outlet of the fertile Majerda valley. Bizerta is a French naval station. Sfax is the port of Southern Tunis.

**Tripoli.** Tripoli (400,000 sq. miles including desert) is fertile round the coast, under irrigation, and for a varying distance inland. Beyond this it is desert, with occasional oases. The capital is Tripoli, the starting point of many caravan routes across the desert. In the south is the large undulating oases of Fezzan, the capital of which is Murzuk, on the caravan route to the Niger Sudan.

**The Sahara.** The Sahara is not a level sea of sand, but a plateau of varying elevation, and varying aridity. It is divided by higher ground into the Western Sahara, extending to the Atlantic, with Lake Chad towards its eastern margin, and the Eastern Sahara, extending to the Red Sea, beyond which lies the Arabian Desert. Vast areas of the Sahara are covered with fine sand, which is piled up by the wind into sand dunes, sometimes 600 ft. high, compared by many travellers to the waves of a sea. Such is the Libyan desert west of the Nile. Here, vegetation is almost absent, except in the oases, on which the dunes frequently encroach. Elsewhere are "isolated plateaux with rock-brown surfaces, bounded by nearly perpendicular cliffs," and destitute of vegeta-

tion. The desert sand is formed of the waste of the bare rocks, which are protected by no covering of vegetation, and are rapidly disintegrated by the action of the weather. Sandstorms of blinding fury are one of the dangers of desert travel. It is believed that the Sahara was once less arid. In many parts dry watercourses are numerous, often associated with salt swamps or shotts, perhaps remnants of lakes to which they once drained.

In some parts of the vast desert the conditions are less forbidding, and there is some scant thorny vegetation, forming pasture of a kind. Wherever wells or springs give access to the underground water, an oasis is formed. The desert is dotted by hundreds of these oases, great and small, and they are the stepping stones by which caravans cross the sea of sand.

**Glimpse of an Oasis.** Here and there, throughout the oasis of Taflet, are large open spaces, usually for drying dates. The walled villages often have a clear space surrounding them of twenty yards or so, to allow a sight of the attacking force in the continual warfare. Nothing more bewildering can be imagined than the roads that thread the oasis. Owing to the great value of land, they are as narrow as possible, and they turn and twist in every direction among the gardens. In these are grown cabbages, onions, peas, beans, grapes, pomegranates, apples, pears, gourds, and melons, but only for the rich, turnips being the favourite vegetable of the poor. Large quantities of lucerne are grown in the shade of the palms, and stored for winter fodder for horses and cattle. It is seldom in the oasis that one's view extends for more than 100 yards or so. This is owing to the thick growth of the date palms, which rise on all sides as a forest of straight stems. The high walls of the gardens also obstruct one's view. These are often so high that only the tops of the trees appear above them. The water from the irrigation canals finds entrance by subterranean channels, while small bridges cross the roads formed by palm trunks covered with sand. The outer portions of the oases are less thickly grown with palms, but the line between the desert sand and the irrigated soil is clearly defined. One walks out of a green field of palm trees ankle deep into soft yellow sand.

**Egypt and the Nile.** Romance and mystery have ever surrounded the Nile. Beside it arose one of the oldest of human civilisations, which has left its great pyramids, its baffling sphinxes, its magnificent temples, and its strange hieroglyphs to prick the curiosity of all who see them. This wonderful civilisation in the heart of the desert depended wholly on the seasonal rise of the Nile, which made fertile a strip of desert on either side of the river. The Nile is the life of Egypt. It is more—it is the creator of Egypt. Inhabited Egypt is made up of layer on layer of Nile mud, brought down year after year by the river in flood, and spread out over the land as the waters ebb. Irrigation has done the rest.

# BREADMAKING

Group 16  
FOOD SUPPLY

Early Forms of Bread. Home-made Bread. Varieties and Grades of Flour. A Home Bakery. Dough. How to keep Yeast

2

Continued from  
page 3095

By JOHN KIRKLAND

THE use of bread in one form or another is almost universal, and, except in the very primary states of society, has always been so. The first form of bread was that made from bruised grains, mixed into a thick paste with water only, then shaped into flat cakes by the hands, and baked on hot embers. Bread of this kind is still made by the native tribes in some parts of Mexico and South America. The breadmaking industry at its inception was necessarily an affair of the home, attended to by the females; but, in comparatively early ages, we find breadmaking had become specialised, and was in the care of men. There is no record of the time when fermented bread was first used, but the discovery of the process may easily have been accidental, since a piece of dough, made from flour and water, if left to itself, especially in those tropical and sub-tropical countries in which the earliest civilisations flourished, would quickly start fermenting, and, if baked, would become lighter than the bread from dough baked at once. In the early Egyptian and Babylonish civilisations the baker was an important functionary in the palaces of kings and the mansions of the great, while in the later Greek and Roman eras, his character and conduct were made the special concern of the State. The Romans had a college of bakers, who, while recruited from the slave class, were granted privileges not allowed to others, and were hedged round with special restrictions; amongst other things, being prevented from associating with comedians and gladiators, or attending gladiatorial shows.

**British Bread Laws.** Within the period of our own history, although the Legislature has not been quite so careful about the baker's privileges, it has never failed to ensure that he should be honest in his dealings with the public. The kinds of materials he should use have been definitely enumerated, and both his weights and his prices have at one time or another been regulated by statutory enactment. But the Bread Act now in force does not, as some imagine, restrict the baker to selling his loaves in 2 lb. and 4 lb. sizes only; all that the law stipulates is that the baker must sell his bread by weight, but leaves him liberty to make his loaves of any weight and size he thinks fit.

Formerly the Worshipful Company of Bakers, which is still a flourishing guild, and has its Hall in Harp Lane, London, was entitled, along with the Justices of the Peace, to settle what should be the weight and price of the bakers' loaves week by week. That was in the old Assize days. Now every baker is a law to himself as to the price at which he shall sell

his bread, the efforts of local voluntary associations to regulate prices being only partially successful. As competition in the trade is very keen the public generally gets full value for its money, and bakers as a class do not become wealthy.

**Plain and Old-fashioned Bread.** To make good bread nothing is required but flour, yeast, salt and water. In some cases there are other substances added, but what these are, and their purpose, will be explained later. Some people are under the impression that there is a great difference between home-made bread and that made by the baker, and a great difference between the bread of, say, forty or fifty years ago and that of to-day; all the virtues being generally ascribed to the home-made in the one case, and to the old-fashioned in the other. Differences do exist, but it is hardly just to depreciate the bakers' bread of to-day. In the bread of some forty or fifty years ago there were two factors entirely different from any in the bread of to-day. The flour was not only softer in character, as it contained a larger proportion of English wheat than our flour, but it was also weaker and darker, because it was milled by stone mills, while ours is made on steel rollers. The great difference between old-fashioned and modern flour is not due wholly to the manner in which it is milled, but more to the manner in which the wheat is cleaned and prepared for the mill. In the old days the wheat-cleaning machines were either very crude or else non-existent, with the result that a good deal of material now considered dirt was mixed with the flour, and consequently eaten in the bread. There is one reason, however, why stone-milled flour should have a better flavour than that made on steel rollers, and that is owing to the presence of minute particles of bran and germ, especially the latter, which the stones have pulverised so fine, that the "bolting silks," or fine sieves, cannot afterwards separate them out from the fine flour. These particles add to the flavour of the flour although they darken its colour, and they in part reduce its keeping qualities, for stone-milled flour becomes much more quickly old in taste, or musty, or sour than does flour made by modern methods.

**"Home-made" or "Farmhouse" Bread.** Within the last year or two there has been quite a revival in favour of bread made from stone-milled flour, and bakers, being quite willing to supply whatever the public demands, provide this article under the title of "Home-made" or "Farmhouse" bread. It is made in some cases wholly, in others partly, from the stone-milled flour and that milled from a "grist" containing a good proportion

of English wheat. The loaf is therefore small and dark as compared with ordinary bread, and is usually made either in a flat shape or in one with the requisite degree of roughness about it to make it look very much as if made by one unskilled in the baker's art.

**Making Farmhouse Bread.** The following method suits this type of bread: Materials are taken in the proportions of 28 lb. of flour, 4 oz. of pressed yeast,  $4\frac{1}{2}$  oz. of salt, and 3 oz. of sugar. Dough is made up at once with  $1\frac{1}{2}$  gallons of water at 100° F., the yeast, salt, and sugar being previously dissolved therein before the flour is added. This dough is then allowed to stand, well covered up in a warm place for  $1\frac{1}{2}$  hours, when it is kneaded together. It is then allowed to stand for another hour, when it is kneaded again, and at once weighed into pieces the size desired—generally 2 lb. 2 oz. These are moulded up round, being rolled in flour during the moulding operation to give the loaves when baked a floury-white appearance. The quantity of water here stipulated may with some flours be hardly sufficient to make the dough quite soft enough, as dough for this sort of bread is usually made *very* soft, so that in some cases half a pint more may be used if necessary. To make the bread cut short and free from toughness, it is advisable to add about 3 oz. of lard to this quantity of flour, rubbing it well into the dry flour, and then thoroughly mixing it. Bread made in this way is not allowed to "prove" or lie any time between the moulding stage and that of "setting" it in the oven. The resultant bread is in consequence rather close in texture, but it is very sweet, and, especially when new, has a pleasant flavour.

**Points on Flour.** Whether flour be made on stones or on rollers its character depends more on the nature of the wheat from which it has been made than on the manner of milling. There are many varieties of English wheat, but none of them are suitable for making very strong flour. Our millers obtain their supplies of strong wheats principally from Russia, the United States, Canada, and the Argentine. For the other parts of the grist they use wheats from all parts of the world; some to give the flour colour, some to modify the excessive toughness of the strong wheats. But by careful blending it is satisfactory to know that British millers, with the world's wheat supplies at command, are now able to make better flour and of more regular quality than the millers of any other country, even than those of America, where supplies of superior wheat can always be had. [See MILLING, page 3078.]

In a stone mill there is really only one grade of flour made; this may weigh as much as 70 per cent. of the total wheat used to manufacture it; the other 30 per cent. being made into what is technically called "offal," consisting of seconds, pollard, bran, etc. Flour of the same grade can be made in a roller mill if desired, and the grade is then called "straight"; but it is usual in the roller mill process to make two or three different grades or qualities of flour from

one mixture of wheat. The very finest grade—that made from the centre of the wheat berry—is called "patent." Of this quality not more than 40 per cent. of the weight of the wheat used may be obtained as flour, the remaining 30 per cent. of the total weight of flour in the wheat being called "low grade." It will thus be seen that the baker has plenty of choice as to the kind of flour from which to make his bread. If he use patent grade, it is white and fine and of delicate flavour, but it is high in price. If he use "straight grade," it is strong but darker than the "patent," and the loaf made from it will neither look so fine outside or inside, nor will it have such a delicate flavour, nor keep so moist. If he use flour of "low grade," his loaf will be dark on the crust, and, when stale, will eat dry and chaffy.

**Influence of Gluten.** The breadmaking qualities of any kind or grade of flour depend on the nature and quantity of the gluten it contains. For ordinary purposes, especially when a short system of fermentation is adopted, a flour with 10 to 11 per cent. of dry gluten is most suitable. But the character of the bread depends again on the extent or degree of change which has taken place in the gluten while the process of fermentation is going on. While the dough is fermenting the gluten gradually changes from a very tough, hard substance to one softer and very elastic. There is a point at which the process has to be stopped if the bread is to be just right, and at this point the gluten is fairly elastic; any baker in the habit of handling dough knows by its feel when he pulls it whether it has reached the proper stage of maturity or not.

If the process be allowed to proceed too far the gluten becomes short and will not stretch, and, in this condition, will not hold the gas generated by the yeast, so that the bread made from dough in this condition will be flat and close in texture with many large holes in it; the crust will be pale in colour, and, instead of showing a plump bold outline will be cracked on the sides and generally unshapely. Bread, on the other hand, made from dough that is unripe will be reddish in colour of crust, and the loaves will also have a drawn and unshapely appearance, while the crumb will be close in some parts and full of elongated holes in others, and when the bread is stale it will become very dry and hard.

**Modern Breadmaking Methods.** In the great majority of bakeries to-day bread is made on what is called the "straight dough" system, to distinguish it from the older methods of "ferment" and dough, and "sponge" and dough. First place must be given to the methods and recipes suitable for modern requirements. It is usual to give all quantities of material in relation to a sack of flour (280 lb.); but, as readers may wish to try making small quantities of bread for domestic purposes, where it may be difficult or even impossible to get supplies from the baker, directions for making smaller quantities may be helpful.

**Keeping Qualities of Fresh Yeast.**

If it be possible to get a supply of fresh compressed yeast say once a week, this can be kept in good condition by pressing it tightly into a stoneware jar, and keeping the jar standing in cold water, covered over with a damp cloth in as cool a situation as possible. If the yeast be fresh and sound when obtained from the baker, grocer, or corn chandler, it should have a pleasant, fruity smell, be moist to the touch, but not sticky, light brown or yellowish in colour, and, when a lump is broken across, it should produce a snapping sound, and show a clean fracture. If yeast be very grey in colour it probably contains a quantity of starch mixed with it, and is, therefore, not so strong. It should not be dark brown on the outside, nor white and crumbly in its interior, as both these appearances are signs of age and deterioration.

**Recipe for a Small Batch.** If the intention be to make 14 lb. of flour into bread two ounces of fresh yeast should be sufficient for the purpose. The flour, after being weighed, is spread on the table in the form of a ring, this ring or "bay" being to hold the water; or, if preferred, it may be placed in a wide, shallow basin, but making dough on the board is much more convenient. This quantity of flour will require, to make a rather slack dough, about three quarts (imperial) of water. The water should be about 105° F. If regular bread is desired it is better to use a small thermometer—which may be obtained for about ninepence—to take the temperature of the water; but, failing that, if tried by the finger, it should be just pleasantly warm, without feeling hot enough to cause the least sensation of scalding. For this quantity of flour three ounces of salt should be used, and one ounce of sugar. The salt and sugar are thoroughly dissolved in about one pint of the water, and the yeast carefully mixed in another pint, care being taken that no small lumps are left unbroken.

**Dough-making.** When these preliminary operations are performed the remainder of the water, except a little for rinsing out the basins in which the salt and yeast were mixed, is poured into the bay, then the liquids containing yeast, salt, etc. The whole is then smartly mixed into dough, and the quicker the flour is drawn into the liquor and the less dry scrap there is, the better the dough. When all the ingredients are lightly mixed, a fresh part of the table should be dusted and the whole transferred to that part. The dough adhering to the hands is rubbed off on to that still adhering to the table, or to the basin, if that has been used, and all is carefully scraped together and transferred to the mass of dough. The remainder of the dough-making operation then consists in well

kneading this mass, turning the sides into the centre, till it is all a tough dough of even texture. It should then be placed in a basin slightly warmed, and covered with a damp cloth. This should be placed in a moderately warm place, away from draughts, for 1½ hours, and then turned out of the basin and well kneaded again. It should then be allowed to stand, covered up as before, for another hour and a quarter. The dough should now be ready for weighing into pieces and moulding.

**Bread Tins.** For domestic purposes it is much better to use tins in which to bake the bread, as there is less depending on the moulding for the shape of the bread, and it is better also to make small loaves weighing not more than, say, 1½ lb., as small ovens have an intense but superficial heat, and very large loaves are in danger of getting burned outside before being properly baked internally.

The tins for bread should be slightly greased and warmed a little before the loaves are placed in them. After the tins are all filled, they should be set in a warm place close together, away from draughts, and covered up with a damp cloth. They are allowed to stand in this condition for about 30 to 35 minutes to "prove," after which they are placed in the oven, as wide apart as space will allow, and baked. The baking operation should not take more than about 25 minutes for loaves of this size. If the oven is heated by gas the heat should be reduced after loaves have been in the oven about 15 minutes, otherwise there is danger of blackening the loaves before they are properly baked. The quantity of flour here used would make about 12 loaves of 1½ lb. each, which could be easily baked in a moderate-sized kitchen oven, or in a gas-stove, but if anyone desired to make larger quantities, a small oven heated by coke or gas can be obtained for about £20, and the cost for fuel is very small.

**"Crusties."** The same procedure may be followed if crusty loaves are preferred; but these take up more space in the oven, and "cottage" shapes are not suitable when small quantities are made. The best form of crusty for domestic baking is the flat, round shape, either cut or uncut, just before being placed in the oven. These are also better for a good "proof," say 20 minutes, between the time of moulding and that of placing in the oven. For this kind of bread each piece of dough is shaped round and placed upside down on a cloth—no dusting is needed—and allowed to lie covered up with another cloth for the time stated. When the loaves are ready for the oven they are turned over and cut across with a sharp knife before setting. Cut loaves must be placed rather wide apart in the oven so as to allow them to open out properly, otherwise, if they touch, the cuts on top do not look nice and bright.

# MORE SHELLFISH

Tusk Shells. Bivalve Molluscs: Oysters, Cockles, and  
Mussels. Rearing and Education of Oysters. Mail Shells

By Professor J. R. AINSWORTH DAVIS

**Tusk Shells.** This is a small group of burrowing marine forms, in which the body is covered by a long, curved shell resembling a tusk in shape [404]. There is a small hole at its tip through which the water which has been used in breathing makes its exit. An imperfectly developed head and a rasping organ are present, and burrowing is effected by a long foot with a three-lobed end. The food consists of small organisms, which are apparently secured by the agency of a bunch of filaments with thickened sticky tips that can be protruded from the mouth of the shell. In some respects these animals are intermediate in structure between typical sea snails and bivalve molluscs, which we will now consider.

**Bivalves.** The most obvious characteristic of this group, which includes oysters, cockles, mussels and the like, is the possession of an external calcareous shell made up of two pieces or valves—i.e., bivalve, not univalve like a snail shell—placed on the right and left sides of the body. They are connected together on the upper side by an elastic ligament, which causes the shell to open, or “gape,” when its action is unopposed, as may be very well seen in specimens from which the soft body of the animal itself has been removed. Along the inner side of the “hinge” of the shell there are often interlocking projections and depressions known respectively as teeth and sockets, and serving to prevent displacement when the shell is opened or closed.

**Opening an Oyster.** Two fleshy bands (sometimes there is only one), the *adductor muscles*, stretch across from valve to valve, one near either end, and when these shorten or contract the shell is tightly closed. Any non-expert who has tried to open an oyster (which has only one such muscle) will testify to the efficiency of the arrangement. Having once succeeded in opening our bivalve, say a fresh-

water mussel (*Anodonta*), by cutting through the adductors, we shall find that each valve is lined by a soft flap of the body-wall. The two together are known as the *mantle*, the chief agent by which the shell is formed. As the animal grows the shell is made correspondingly larger, lines of growth marking the successive additions. These lines all circle round the pointed beak (*umbo*) which is the oldest part, and is typically near the front end.

On raising the mantle-flap of either side [405], we at once see the complicated plate-like gills (*Lamellibranchia* means “plate-gills”), and

an orange-coloured foot, shaped like an axe-head and projecting to the front. Bivalves, with few exceptions, are essentially burrowers, and the foot is the agent by which this kind of locomotion is effected. Blood is pumped into it so that it stretches forward, and then by contraction of its muscular fibres a shortening is effected by which the body is dragged onwards.

**Brainless Molluscs.** At the front end of our mussel we shall find a mouth, but no distinct head—indeed, bivalves are often known as the “headless” molluscs. Nor is there any rasping organ, as in snails and cuttles, yet this,

as well as a head, was probably present in the remote ancestral types from which bivalves have descended. An explanation of such deficiencies is probably to be found in the curious method of feeding. The food consists of all sorts of minute organisms and nutritive particles, and these are brought in by currents of water which continually stream in through an opening between the mantle flaps at the back, and also serve for the purposes of breathing. A return current, carrying with it the various products of waste, passes out through a second aperture above the first (indicated by arrows in 408).

These currents of water, which do the feeding, breathing, and scavenging work, are not set up

by the will of the animal, but are produced by the constant movement of microscopic threads of living matter (*cilia*) that beset the gills and inner surface of the mantle. Such a lazy way of getting a living does not demand much brain, and it is therefore intelligible that the head should have become reduced. And the same fate would seem to have befallen the rasping organ because the food is not of a character that requires breaking up.

**Seeing Without Eyes.** There are many bivalves in which the back of the mantle is drawn out into either two tubes (*siphons*) or else a single one with two distinct passages, as in the otter shell (*Lutraria*) [406], along which the incoming and outgoing currents of water can respectively flow, as indicated by arrows in the illustration. Such a bivalve can remain sheltered in its vertical burrow in the sand or mud, and so long as its siphons just reach the surface is able to feed and breathe with comfort. The ends of the siphons are pigmented, and sensitive to changes of light. Should a shadow fall upon them, an occurrence which commonly points to the presence of an enemy, they are drawn in, and their owner will begin to burrow away from the surface, so as to be out of danger. This may be called a case of "seeing without eyes," the most primitive sort of vision with which we are acquainted.

Some bivalves burrow in mud or sand much more rapidly than others, those which are best endowed in this respect possessing a long, narrow shell with the foot projecting right in front. The razor shells (*Solen*) present these characters in the most marked degree. Some species are able to bore in wood or stone, the roughened front end of the shell being the implement employed, while the body can be twisted on its long axis so as to bring this to bear. Date shells (*Lithodomus*) and piddocks (*Pholas*) are good examples [403]. The most notorious wood borer, however, is the so-called "ship worm" (*Teredo*), which plays havoc with the timbers of ships, and has proved a serious nuisance to the Dutch by riddling the wooden piles of the great dams which keep out

the sea from their low-lying coast. The tunnels of the ship-worm are lined by a smooth calcareous layer [408].

**Fixed Bivalves.** A considerable number of bivalves have specialised on what may be called sluggish lines, becoming temporarily or permanently fixed when adult. An early stage of this is seen in the edible mussel (*Mytilus edulis*), which moors itself to fixed objects by means of black silky threads (*byssus*) [407]. Should the conditions become unfavourable it is able to cast off these threads, and seek a fresh home, though the small size of the foot shows that it is ceasing to lead an active life. In scallops (*Pecten*) the foot is reduced to an useless vestige, and the shell has become somewhat rounded [409]. There is one large muscle only for pulling the valves together. The animal lies upon its right side, and the two valves are dissimilar. The most typical example of a fixed bivalve is the oyster (*Ostrea*), which has entirely lost its foot, and possesses a more or less rounded irregular shell with only one closing muscle, centrally placed. The animal is fixed by the substance of the deeply concave left valve, while the flattened right valve serves as a kind of lid, which can be raised for the admission of water currents.

All the marine bivalves start life as minute free-swimming larvae or "fry," so that even the fixed forms are able to reach fresh homes. These little creatures settle down after a time, and become "spat," which, in the case of oysters, become attached to stones, shells, or other firm bodies. Arrangements for catching the spat play a large part in oyster culture as practised in many countries. The early stages of development, before hatching, are often spent within the shells or gills of the parent.

**Life Story of the Mussel.** A number of bivalves live in fresh water, and in such cases there are either no free-swimming larvae, which would be liable to get swept down to sea and perish, or, if they are formed, special arrangements prevent such a catastrophe. The latter alternative is found in the life history of the ordinary freshwater mussels (*Anodonta* and *Unio*). Development takes place in the outer

## NATURAL HISTORY

gills of the mother, and when the little larva (*glochidium*) is hatched, it passes out to the exterior. The shell is quite unlike that of the adult, for the valves are triangular and hooked, and a long, sticky byssus-thread trails in the water [410]. Should this thread touch the gills or skin of a fish, say a stickleback, it holds fast, and the larva quickly uses the hooked shells as a means of attachment. The irritation which is set up leads to the growth of a sort of gall, within which the later stages are comfortably passed through, and the young mussel ultimately falls from its temporary home into the mud, where it lives for the rest of its life.

Some few bivalves such as the common cockle (*Cardium edule*) are able to make considerable leaps by suddenly straightening the bent foot. Others are able to swim by flapping their shells, as in some of the smaller scallops and file shells (*Lima*). In such cases as the last the mantle edges are fringed with delicate tentacles, and studded with numerous eyes of a red or orange colour [409].

**Oyster Culture.** Oysters have been esteemed as a delicacy from remote times, those of Whitstable, for example, being well known to the

ancient Romans. They thrive best where there is a certain admixture of fresh water, as in estuaries, a habit which is not without danger to the epicure. For the minute organisms on which these shellfish feed include bacteria, including some of those producing serious diseases. The germs of typhoid fever, taken up from infected sewage, can be disseminated in this way.

In order to secure a regular supply of oysters, various methods of culture have been employed for many centuries, sometimes without much improvement, as in Italy, where these toothsome bivalves are reared in much the same fashion as they were in classical times. But in other countries, such as Holland and France, oyster culture has become a very elaborate matter. The latter country will serve as an example. [For details see Fisheries.]

The natural oyster-beds of France are carefully preserved, and serve as the source of the free-swimming larvæ or spat, the collection of which is the first object of the industry. The "collectors" are crates of lime-washed earthenware tiles placed on the shore between tide marks. To these tiles the spat attach themselves when the free-swimming life is abandoned.

After a time the minute "seed oysters" are flaked off the tiles and placed in shallow trays covered with wire gauze for further development. They are subsequently transferred to carefully-prepared oyster-beds, some of which are walled in and provided with flood-gates for regulating the supply of water.

In some cases, as at Marennes, the culture also includes fattening, greening, and education for transport. The two former take place in ponds and trenches, full of brackish water swarming with microscopic algae. It is these which impart the delicate green colour prized by epicures. It should be mentioned, however, that some oysters are green from the presence of copper compounds, and these are decidedly deleterious or even poisonous.

Education for transport consists of keeping out of water

for a certain time such oysters as "gape" when removed from their natural element. By a repetition of this process the molluscs learn to keep their shells closed, and are then ready to travel. Some oysters, of course, do not need this kind of "education," having already learned from their own experience to "shut up" when brought to land.

**Mail Shells.** The mail shells (*Chiton*, etc.) are oval, flattened creatures which live under stones round the coast, and correspond more nearly than any other living forms to the remote ancestors from which all shellfish have descended. The upper side of the body is protected by eight overlapping shelly plates, and on the under side a long, flat foot, an imperfect head, and numerous gills may be seen [411]. Some of these forms roll themselves up like hedgehogs when alarmed.

# PSYCHICAL RESEARCH

The Mystery of Life. The Two Minds of Man.  
The Ultimate Reunion of the Universal Soul

Group 3  
PSYCHOLOGY

10

Continued from page 3120

By HAROLD BEGBIE

THERE is an inclination in the average mind to make a duality of existence, and to say of one division, which people call the *physical*, that it is comprehensible; and of the other, which people call the *psychical*, that it is incomprehensible.

For the convenience of our argument, we will accept the proposition that existence can be divided into these two parts. Let us, then, look at the physical division, which men of science profess their ability to handle, and see how far their investigations carry us in absolute knowledge. We ask, to begin with, of what the earth is made; and we are told matter. We ask what is matter; and we are told that it is probably electricity. What is electricity? we ask; and we are told that nobody knows. The visible, tangible, and sonorous earth is a mystery.

If we ask them what they understand by gravitation, they are equally unable to tell us. They know that gravitation is a fact, just as electricity is a fact; but what it is no man knows.

**The Mystery of Life.** We ask the physicists to tell us about birth and death—the two most obvious facts of the material universe. Here, in a measure, they become voluble; but when we ask them to state the difference between a live dog and a dead dog they are silent again. The greatest of them admit at once that we have no knowledge on this head beyond a general biological hypothesis on the one hand, and a few physiological facts on the other. Of life they know nothing, and of death they know no more.

As a writer has very well put it, physical science knows only about "the outside of things." Of the mystery of life it knows nothing. Now, it is not often seen that mystery is not to be driven into one of the divisions of knowledge—the division called psychical—but that it obstinately holds its place in the other division as well, the division called physical. It is this point which we would establish as our first justification for approaching what are called the mysteries of life. Many people besides physicists tell mankind that mysteries are sacred things not to be handled by mortality. The answer is that, if indeed this be the case, then we must sit with folded hands and closed eyes, since all is mystery. The man of science who investigates invisible and intangible electricity is guilty of a blasphemy. Cohesion is a mystery. There is no man of science who can explain how it is that this solid globe swims through ether without disturbing it. The very simplest facts of life share the universal mystery, and the human division of things into material and psychical is but a clumsy evasion of the one all-present and eternal mystery—the mystery of life.

**The Search after Truth.** Psychical science, rightly understood, does not work in a field by herself, but seeks in the field of all inquiry to intensify the culture. She is not set upon proving communication between the dead and the living; her ambition is not to clutch the vanishing garments of ghost and goblin. She is the enthusiast for truth who preaches to all who profess and call themselves men of science honesty and courage. She holds the great principles of philosophy, and believes nothing until it is proved. She enters upon her work with no preconceived theories, with no bias, and with no enmity. She is the great encourager of human effort to understand the universe, and her word to those who are so patiently and so splendidly engaged with the outside of things is a word, not of mockery, but of cheer. In a word, the phrase "psychical science" is merely an expression of that constant attitude of the human mind towards the mystery of life—namely, the assured conviction that we are destined to discover truth.

**Is Man an Immortal Soul?** Psychical science has come to mean in the minds of the multitude a search after the impossible, or a study of the incomprehensible. Our point at present is this: that physical science in seeking to understand gravitation and cohesion, is seeking to understand what is incomprehensible; and that psychical science is not a hunter after ghosts and goblins, but a systematic effort to begin at the beginning of human inquiry by investigating the mind with which the physicists engage upon their problems. If we were to sum up the effort of psychical science into one sentence, we might say that it is to answer the most precious of all questions—"What is consciousness"? And consciousness, we hold, is no less a mystery than gravitation or cohesion, and yet, in answering that question, we shall hold an answer to that oldest of all questions—"Is man an immortal soul"?

Two hypotheses concerning man's personality have been stated in recent years. The one comes from America, the other from England. The propounder of the first hypothesis is Mr. Thomson Jay Hudson, author of "The Law of Psychic Phenomena"; and the propounder of the second is Frederic W. H. Myers, author of "Human Personality."

We proceed in this place to state the hypothesis propounded by Mr. Hudson. In his search for some working hypothesis universal in its application to psychic phenomena, Mr. Hudson was careful to examine some of the obscure phases of mental aberration which, as a rule, are neglected by professors more anxious, perhaps, to state a theorem than to substantiate

its logic. The hypothesis advanced by Mr. Hudson is based not only upon a remarkably wide knowledge of hypnotism, but upon a pretty general observation of mysterious aberrations in human personality which have to be explained if we are to arrive at any just and catholic conclusion concerning the nature of man.

**The Two Minds.** Mr. Hudson's labours led him to a hypothesis with these propositions: (a) that man has two minds—the objective or physiological mind, and the subjective or spiritual mind; (b) that the subjective mind is constantly amenable to control by suggestion; and (c) that the subjective mind is incapable of inductive reasoning.

These three propositions are of the very highest importance, and before proceeding to state them in greater fulness we propose to make them a little more clear to the mind of the reader unacquainted with the language and methods of psychical investigation.

Of old time it was said that Man consisted of a trinity—his body, his mind, and his spirit. The body was the outward and tangible sign of the man; the mind was the inward and invisible working of the machinery of the man; and the spirit was the ineffable essence which composed the personality and individuality of the man, differentiating him from his fellows. The surgeon of modern days would do away with the third person of this trinity; that which the ancients called the spirit, he affirms, is to be found in the grouping of the brain cells, and personality consists almost entirely of memory, which can be destroyed by damage of the matter composing the brain. Mr. Hudson holds a contrary opinion, and adduces evidence to prove that there is in man a mind separate altogether from the physical mind which is subject to the laws of Nature and can be easily destroyed. This indestructible mind he calls the Subjective Mind. Man, therefore, according to this theory, consists of the ancient trinity—a body, a physical mind, and a spiritual Ego. The body you can harm, the physical mind you can educate or destroy, the subjective mind is independent of terrestrial conditions.

This fundamental truth, it is held, is the real basis of Man's conception of God as a Trinity "in His personality, modes of existence, and manifestations." Schelling says: "The philosophy of mythology proves that a trinity of divine potentialities is the root from which have grown the religious ideas of all nations of any importance that are known to us." In fact, from the earliest ages of human thought this theory of the threefold nature of man has been pretty generally held. But Mr. Hudson's service lies in the lucid and laborious manner in which he has defined the nature of the two elements constituting the dual mind.

**Functions of the Two Minds.** The line of demarcation between the two minds, he declares, is clearly defined; their functions are essentially unlike; each is endowed with separate and distinct attributes and powers; and each is capable, under certain conditions and limitations, of independent action. And

then he states very clearly what he takes to be the difference between these two minds:

"The *objective mind* takes cognisance of the objective world. Its media of observation are the five physical senses. It is the outgrowth of man's physical necessities. It is his guide in his struggle with his material environment. Its highest function is that of reasoning."

So far, the objective or natural mind known to the physiologist. As for the spiritual mind, we learn:

"The *subjective mind* takes cognisance of its environment by means independent of the physical senses. It perceives by intuition. It is the seat of the emotions, and the storehouse of memory. It performs its highest functions when the objective senses are in abeyance. In a word, it is that intelligence which makes itself manifest in a hypnotic subject when he is in a state of somnambulism."

The reader has now obtained, we hope, a clear idea of what Mr. Hudson means by the objective mind and the subjective mind. He has learned that the objective mind has to do with the objective world, and is man's chief guide along the path of evolution; while the subjective mind, independent as it is of the physical senses, is irrational, and arrives at its conclusions by means of what we call intuition. We will now examine in greater detail the last two propositions on which is based Mr. Hudson's hypothesis of the Dual Mind.

**Actions without Reason.** The second proposition declares that "the subjective mind is constantly amenable to control by suggestion." Now, the reader will know that while he can give a logical reason for many of his opinions there are yet certain definite and important convictions helping to compose his personality for which he can give neither to himself nor to others a valid justification. We know why we prefer gold to silver, why we light a fire when it is cold, why we use our feet and not our hands when we go for a walk; for all these things the objective mind can provide a convincing logic. But are there not a thousand things in the day which are settled for us without any exercise of reasoning on the part of the objective mind? Nay, is not the greater part of our life, our emotions and sensibilities, independent of the reasoning process? We are instantly drawn to one person, and repelled by another; a certain scent pleases us, another disgusts; we set out to do a thing, when suddenly we are turned back and desist from it; someone persuades us to a course of action which is against our reason, while another, by his very advocacy, makes us refuse to do that which he counsels and of which our reason fully approves. In fact, the reader will easily name for himself a thousand and one things which occupy him and control him without the smallest decision of his reasoning power.

But while this independence of the subjective mind is more or less clear in normal life, there is a certain abnormal state in which it becomes so

remarkably manifest that the man of science is brought to readjust all his old theories concerning human personality.

**Credulity under Hypnotism.** We refer to the state of *hypnosis*. In the state of hypnosis the subjective mind is always amenable to suggestion. Nothing is too monstrous for its credence, nothing too fantastic for its acceptance. The objective mind will not accept, often enough, the most palpable truths of daily life, labouring through the process of logic to discover some flaw in the hypothesis whereby it may escape belief; but the subjective mind never reasons, and let a thing be suggested to it in hypnosis, never mind how grotesque, and it yields incontinently a ready assent to its veracity.

"If a subject is told," says Mr. Hudson, "that he is a dog, he will instantly accept the suggestion and, to the limit of his physical possibility, act the part suggested. If he is told that he is the President of the United States, he will act the part with wonderful fidelity to life. He may be thrown into a state of intoxication by being caused to drink a glass of water under the impression that it is brandy; or he may be restored to sobriety by the administration of brandy, under the guise of an antidote to drunkenness. If told that he is in a high fever, his pulse will become rapid, his face flushed, and his temperature increased. In short, he may be made to see, hear, feel, smell, or taste anything, in obedience to suggestion. He may be raised to the highest degree of mental or physical exaltation by the same power, or be plunged by it into the lethargic or cataleptic condition, simulating death."

The reader will perceive that if, during hypnosis, a man's subjective mind can be so influenced by another, it follows that in daily life this same subjective mind is constantly under the influence of the man's objective mind. Think with the objective mind of disaster and ruin, and the subjective mind will become morose and paralysed; think constantly, on the other hand, of success and gratitude, and the subjective mind will become quick with a cheerful and most salutary enthusiasm. A man's life, then, is largely influenced by the suggestions that he receives, both from himself and from other people. The subjective mind—as Mr. Hudson's second proposition declares—is constantly amenable to suggestion.

**A Hint of the Afterward.** We will now take the third proposition—namely, that the subjective mind is incapable of inductive reasoning. Now, the student must perceive that the reasoning powers on which man very properly prides himself are, after all, the groupings of a finite being necessitated by an environment of which he is naturally ignorant. We use our reason to find our way about the earth. Our reason uses such ideas as those of time and space—things which cannot possibly have any existence or meaning. All this is necessary if we are to arrive at any conclusion concerning our little environment, the earth and

its limited atmosphere. But do we suppose that the reason will play any part in spiritual states? What shall we know of hours and years in eternity, or of miles and furlongs in the fields of infinity? Outside this earth, we must think, there are processes far different from those of the painful and stumbling functions of the brain for arriving at knowledge or for compassing achievement. And the subjective mind seems to give us a faint hint of what those processes may be.

**The Mind that Cannot Reason.** The subjective mind does not reason, it *creates*. Tell a person in the hypnotic trance that a chair is the Archangel Michael, and it will bow down in worship. Let the objective mind pity this credulity how it may, the subjective mind will be content in its creation. For it, the chair is an angel, and nothing else matters. The soul of a man can suggest to itself the most alluring of heavens, or the most dismal of hells; can build itself out of airy nothing gorgeous palaces and delightful gardens; and in whatsoever circumstances it find itself, can become, at its own suggestion, any shape or thing its aspirations may desire. The subjective mind, then, which is constantly amenable to suggestion, is incapable of deductive reasoning.

And now, in conclusion, let us follow Mr. Hudson's answer to the natural question: "Why is it that God has given to man a soul possessing such transcendent powers in certain directions, and yet under the absolute control, in all its ideas and intellectual functions, of a finite, perishable intelligence?" In another form, "How is it that the subjective mind, so superior in its powers to the objective mind, is yet in subjection to this purely material and finite intelligence?"

**Man is a Free Moral Agent.** The broad and comprehensive answer, says Mr. Hudson, is that God has so ordered things in order "to constitute man a free moral agent." It needs no argument, he proceeds, to show that if the soul were not so limited in its initiative power of reasoning, the finite, mortal man could not be held responsible for the moral status of his soul. God gave the objective man the powers of reason, inductive as well as deductive, for the purpose of enabling him successfully to struggle with his physical environment. He gave him the power to know the right from the wrong. He gave him supreme control of the initial processes of reasoning, and thus made him responsible for the moral status of his soul. The soul, in the meantime, so long as it inhabits the body, is charged with limited responsibilities. It is the life principle of the body, and its normal functions pertain solely to the preservation of human life and the perpetuation of the human race.

We do not pretend that Mr. Hudson's reasoning is conclusive, nor do we desire the reader to think that we have here presented him with the final hypothesis of human personality. But we feel persuaded that Mr. Hudson has done valuable service to psychical research in insisting upon the two incontrovertible facts.

# QUADRATIC EQUATIONS

Nature of the Roots Found by Inspection. Relations between the Roots and the Coefficients. Simultaneous Quadratic Equations. Problems

By HERBERT J. ALLPORT, M.A.

**98. Nature of the Roots of a Quadratic.** In Article 96 it was shown that every quadratic equation reduces to the form

$$ax^2 + bx + c = 0,$$

and that the solution is

$$x = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \text{ and } x = \frac{-b - \sqrt{b^2 - 4ac}}{2a}.$$

From this it appears that a quadratic equation has two, and only two, roots.

If the expression under the square root sign,  $b^2 - 4ac$ , equals 0, then each root reduces to  $-\frac{b}{2a}$ . In this case the equation is said to have

two equal roots. If  $b^2 - 4ac$  is a perfect square, the values of  $x$  are *rational*, i.e., can be expressed without a square root sign, and are unequal.

If  $b^2 - 4ac$  is not a perfect square, the values of  $x$  are still unequal, but are also *irrational*, i.e., we cannot find their *exact* value.

If  $b^2 - 4ac$  is negative, the roots are *imaginary*; for, we cannot take the square root of a negative quantity, since by the law of signs the square of any quantity must be positive.

Finally, if  $b = 0$ , the values of  $x$  become

$$+\frac{\sqrt{-4ac}}{2a} \text{ and } -\frac{\sqrt{-4ac}}{2a},$$

i.e., they are equal in value, but opposite in sign.

It should be noticed, from the above, that if one root of a quadratic is irrational, then *both* are irrational, and if one root is imaginary, then *both* roots are imaginary.

**99. Additional Roots.** In simplifying an equation, it is often necessary to multiply both sides of the given equation by the same quantity. The resulting equation will, of course, be satisfied by all the values of  $x$  which satisfy the given equation. But, if we multiply both sides by an *integral expression containing  $x$* , the resulting equation will also be satisfied by any value of  $x$  which makes this integral expression equal to zero.

For this reason we must always be careful to multiply by the *least* common multiple of the denominators.

**Example.** In the equation

$$\frac{1}{x-2} - \frac{2}{x+2} = \frac{3}{x^2-4}$$

the L.C.M. of the denominators is  $x^2 - 4$ . Multiplying both sides by  $x^2 - 4$ , we get

$$(x+2) - 2(x-2) = 3,$$

whence

$$x = 3.$$

But if, instead of multiplying by the *least* common multiple, we use, say,  $(x-2)(x^2-4)$ , we get

$$(x^2-4) - 2(x-2)^2 = 3(x-2).$$

Therefore,

$$x^2 - 5x + 6 = 0;$$

which gives

$$x = 2, \text{ or } x = 3,$$

and the value  $x = 2$  does not satisfy the original equation.

**100. Relations between the Coefficients and the Roots of a Quadratic Equation.** It is usual to denote the roots of the general quadratic equation by the Greek letters  $\alpha$  and  $\beta$ . Thus,

$$\alpha = \frac{-b + \sqrt{b^2 - 4ac}}{2a},$$

$$\beta = \frac{-b - \sqrt{b^2 - 4ac}}{2a}.$$

By addition we have

$$\begin{aligned} \alpha + \beta &= \frac{-b + \sqrt{b^2 - 4ac}}{2a} - \frac{b - \sqrt{b^2 - 4ac}}{2a}, \\ &= \frac{-2b}{2a} = -\frac{b}{a}. \end{aligned}$$

And, by multiplication,

$$\begin{aligned} \alpha\beta &= \frac{(-b + \sqrt{b^2 - 4ac})(-b - \sqrt{b^2 - 4ac})}{2a \cdot 2a}, \\ &= \frac{(-b)^2 - (\sqrt{b^2 - 4ac})^2}{4a^2} = \frac{b^2 - b^2 + 4ac}{4a^2}, \\ &= \frac{4ac}{4a^2} = \frac{c}{a}. \end{aligned}$$

But, by dividing every term of  $ax^2 + bx + c = 0$  by  $a$ , we get

$$x^2 + \frac{b}{a}x + \frac{c}{a} = 0,$$

and, by what has just been proved, this is equivalent to

$$x^2 - (\alpha + \beta)x + \alpha\beta = 0.$$

Thus, in a quadratic equation in which the coefficient of  $x^2$  is unity, the sum of the roots is equal to the coefficient of  $x$  with its sign changed, and the product of the roots is equal to the term independent of  $x$ .

This result is of great importance. Instances of its use are seen in the following examples.

**Example 1.** Form the equation whose roots are the squares of the roots of the equation  $x^2 + 3x - 5 = 0$ .

One way of finding the required equation would be to solve  $x^2 + 3x - 5 = 0$ , and then square the roots. But, by Article 98, since  $b^2 - 4ac$ , i.e.,  $3^2 + 4 \cdot 5$ , equals 29, we see that the roots of the given equation are irrational; so that to find their actual value and square those values would be, at the least, clumsy. We therefore proceed as follows, and avoid finding the values of the roots altogether.

Let  $\alpha$  and  $\beta$  be the roots of  $x^2 + 3x - 5 = 0$ .  
Then, by the present Article,

$$\begin{aligned}\alpha + \beta &= -3 \\ \alpha\beta &= -5.\end{aligned}$$

The roots of the required equation will be  $\alpha^2$  and  $\beta^2$ , so that the sum of its roots

$$\begin{aligned}&= \alpha^2 + \beta^2 \\ &= \alpha^2 + 2\alpha\beta + \beta^2 - 2\alpha\beta \\ &= (\alpha + \beta)^2 - 2\alpha\beta \\ &= 9 + 10 = 19\end{aligned}$$

and the product of its roots

$$= \alpha^2 \cdot \beta^2 = (\alpha\beta)^2 = (-5)^2 = 25.$$

Hence, since the required equation has 19 for the sum of its roots, the coefficient of  $x$  must be  $-19$ , and since the product of the roots is 25, the term independent of  $x$  is 25, the coefficient of  $x^2$  being 1. Thus the required equation is

$$x^2 - 19x + 25 = 0.$$

**Example 2.** Find what relation there must be between the coefficients of the equation  $x^2 - px + q = 0$  in order that one root may be three times the other.

Let  $\alpha$  be one root of the equation.

Then  $3\alpha$  is the other.

The sum of the roots

$$= p.$$

Therefore,

$$4\alpha = p. \quad (1)$$

Their product

$$= q.$$

Therefore,

$$3\alpha^2 = q. \quad (2)$$

If we *eliminate* (Art. 49)  $\alpha$  from (1) and (2), we shall obtain the required relation between  $p$  and  $q$ .

Squaring (1) we get

$$16\alpha^2 = p^2.$$

Dividing this result by (2)

$$\begin{aligned}16\alpha^2 &= p^2 \\ 3\alpha^2 &= q\end{aligned}$$

or

$$3p^2 = 16q.$$

**101.** Any quadratic whose roots are given, may be formed by the method of Example 1 of the last article, *i.e.*, add the given roots together, and change the sign to form the coefficient of  $x$ , and multiply them together to obtain the third term.

**Example.** Form the equation whose roots are  $-\frac{1}{2}$  and  $+\frac{2}{3}$ .

Sum of roots

$$= -\frac{1}{2} + \frac{2}{3} = \frac{1}{6}.$$

Product of roots

$$= \left(-\frac{1}{2}\right)\left(\frac{2}{3}\right) = -\frac{1}{3}.$$

Therefore, required equation is

$$x^2 - \frac{1}{6}x - \frac{1}{3} = 0;$$

or

$$6x^2 - x - 2 = 0.$$

Or, we may use the converse of the method of solution by factors. For, since the equation  $(x-2)(x-3)=0$  is satisfied by the values  $x=2$  and  $x=3$ , it is clear that the converse is true, *viz.*, that the equation whose roots are 2 and 3 is  $(x-2)(x-3)=0$ . This method is

applicable to equations of a higher degree than the second.

**Example.** The equation whose roots are  $-\frac{1}{2}$ ,  $+\frac{1}{2}$ , and 1 is

$$(x + \frac{1}{2})(x - \frac{1}{2})(x - 1) = 0;$$

or

$$(2x + 1)(2x - 1)(x - 1) = 0,$$

*i.e.*,

$$4x^3 - 4x^2 - x + 1 = 0$$

## EXAMPLES 28

Solve the following equations

1.  $\frac{3}{2(x^2-1)} + \frac{x}{4(x+1)} = \frac{3}{8}$ .
2.  $\frac{x+4}{3} - \frac{7-x}{x-3} = \frac{4x+1}{9}$ .
3.  $\frac{3}{4} \cdot \frac{x-5}{2x-7} - \frac{4}{5} \cdot \frac{2x-7}{x-5} = \frac{2}{5}$ .
4.  $\frac{3x-2}{2x-5} - \frac{2x-5}{3x-2} = \frac{8}{3}$ .

If  $\alpha$ ,  $\beta$  are the roots of  $x^2 - px + q = 0$ , find the value of

$$5. \frac{\alpha}{\beta} + \frac{\beta}{\alpha}, \quad 6. \frac{1}{\alpha^3} + \frac{1}{\beta^3}, \quad 7. \frac{\alpha}{\beta^2} - \frac{\beta}{\alpha^2}.$$

8. If  $\alpha$ ,  $\beta$  are the roots of  $3x^2 - 4x + 2 = 0$ ,

form the equation whose roots are  $\frac{1}{\alpha}$  and  $\frac{1}{\beta}$ .

9. Find the condition that the roots of  $x^2 + px + q = 0$  may be the squares of the roots of  $x^2 + px + q = 0$ .

## SIMULTANEOUS QUADRATIC EQUATIONS

**101.** We shall now consider simultaneous equations, one or both of them being of the second degree.

**Example 1.** Solve

$$x + y = 5, \quad (1)$$

$$xy = 6. \quad (2)$$

Here we are given the value of  $x + y$ . If we can find the value of  $x - y$ , the solution of these two simple equations will give the values of  $x$  and  $y$ .

By squaring (1) we have

$$x^2 + 2xy + y^2 = 25.$$

Subtract 4 times (2) from this result, and we get

$$x^2 - 2xy + y^2 = 25 - 24 = 1.$$

Therefore, taking the square root,

$$x - y = \pm 1.$$

We have now the two sets of equations

$$\begin{aligned}x + y &= 5 \\ x - y &= 1\end{aligned} \quad \text{and} \quad \begin{aligned}x + y &= 5 \\ x - y &= -1\end{aligned}.$$

The solution of the first set gives

$$x = 3, y = 2,$$

and of the second

$$x = 2, y = 3.$$

**Example 2.** Solve

$$x - y = 4. \quad (1)$$

$$xy = 12. \quad (2)$$

In this case we find the value of  $x + y$  by squaring (1) and adding 4 times (2). This gives  $x^2 + 2xy + y^2 = 16 + 48 = 64$ , and taking the square root we get  $x + y = \pm 8$ . We now

proceed as in Example 1, and obtain  $x = 6$ ,  $y = 2$ , and  $x = -2$ ,  $y = -6$ .

102. Other cases are largely dependent on the two simple examples already given.

Example 1. Solve

$$x^2 + y^2 = 25. \quad (1)$$

$$x + y = 7. \quad (2)$$

Square (2)

$$x^2 + 2xy + y^2 = 49. \quad (3)$$

Subtract (1) from (3)

$$2xy + 49 - 25 = 24. \quad (4)$$

Subtract (4) from (1)

$$x^2 - 2xy + y^2 = 1.$$

Therefore,

$$x - y = \pm 1. \quad (5)$$

By solving the sets of equations contained in (2) and (5) we have

$$x = 3, y = 4, \text{ and } x = 4, y = 3.$$

Example 2. Solve

$$x^2 + y^2 = 65. \quad (1)$$

$$xy = 28. \quad (2)$$

From (2)

$$2xy = 56. \quad (3)$$

Add (1) and (3)

$$x^2 + 2xy + y^2 = 121.$$

Therefore,

$$x + y = \pm 11. \quad (4)$$

Subtract (3) from (1)

$$x^2 - 2xy + y^2 = 9.$$

Therefore,

$$x - y = \pm 3. \quad (5)$$

From (4) and (5) we have four sets of equations, namely,

$$\left. \begin{array}{l} x + y = 11 \\ x - y = 3 \end{array} \right\} \left. \begin{array}{l} x + y = -11 \\ x - y = -3 \end{array} \right\} \left. \begin{array}{l} x + y = 11 \\ x - y = -3 \end{array} \right\} \left. \begin{array}{l} x + y = -11 \\ x - y = 3 \end{array} \right\},$$

the solutions of which are

$$\left. \begin{array}{l} x = 7 \\ y = 4 \end{array} \right\} \left. \begin{array}{l} x = -4 \\ y = -7 \end{array} \right\} \left. \begin{array}{l} x = 4 \\ y = 7 \end{array} \right\} \left. \begin{array}{l} x = -7 \\ y = -4 \end{array} \right\}.$$

Example 3. Solve

$$x^4 + x^2y^2 + y^4 = 91. \quad (1)$$

$$x^2 - xy + y^2 = 7. \quad (2)$$

Divide corresponding sides of equations (1) and (2), thus

$$\frac{x^4 + x^2y^2 + y^4}{x^2 - xy + y^2} = \frac{91}{7};$$

or

$$x^2 + xy + y^2 = 13. \quad (3)$$

Subtract (2) from (3),

$$2xy = 6;$$

or

$$xy = 3. \quad (4)$$

By adding (3) and (4) and taking the square root, we obtain

$$x + y = \pm 4. \quad (5)$$

and, by subtracting (4) from (2), and taking the square root, we obtain

$$x - y = \pm 2. \quad (6)$$

As in the last example, (5) and (6) give four sets of equations, the solutions being

$$\left. \begin{array}{l} x = 3 \\ y = 1 \end{array} \right\} \left. \begin{array}{l} x = 1 \\ y = 3 \end{array} \right\} \left. \begin{array}{l} x = -1 \\ y = -3 \end{array} \right\} \left. \begin{array}{l} x = -3 \\ y = -1 \end{array} \right\}.$$

The student should find no difficulty in applying the method to other forms. Remember that we can always solve the equations if we can find the *product* of the unknowns, and either their *sum* or their *difference*.

103. If the equations are *homogeneous* as regards  $x$  and  $y$  [see Article 30, page 2149], we can always solve them in the following way. Divide one equation by the other; simplify and resolve the result into factors. This gives  $x$  in terms of  $y$ . If these values of  $x$  are substituted in either of the given equations we get a quadratic in  $y$ , and the rest of the process is evident.

Example. Solve

$$x^2 - 3y^2 = 22. \quad (1)$$

$$xy - 2y^2 = 3. \quad (2)$$

Divide corresponding sides of the given equations,

$$\frac{x^2 - 3y^2}{xy - 2y^2} = \frac{22}{3}.$$

Multiplying by the L.C.M. of the denominators, we have

$$3(x^2 - 3y^2) = 22(xy - 2y^2);$$

or

$$3x^2 - 22x - 35y^2 = 0.$$

Therefore, resolving into factors,

$$(3x - 7y)(x - 5y) = 0.$$

Therefore,

$$x = 5y;$$

or

$$x = \frac{7}{3}y.$$

We now substitute, in turn, these values of  $x$  in either of the given equations, and so obtain a quadratic involving only  $y$ . In this case, it is simpler to use equation (2).

Taking  $x = 5y$  we have

$$5y^2 - 2y^2 = 3.$$

Therefore,

$$\begin{aligned} 3y^2 &= 3, \\ y^2 &= 1, \\ y &= \pm 1; \end{aligned}$$

and since

$$x = 5y,$$

we get

$$x = \pm 5.$$

Again, substituting  $x = \frac{7}{3}y$  in the same equation, we get

$$\frac{7}{3}y^2 - 2y^2 = 3.$$

Therefore,

$$\begin{aligned} y^2 &= 9 \\ y &= \pm 3; \end{aligned}$$

and

$$x = \frac{7}{3}y = \frac{7}{3} \text{ of } \pm 3 = \pm 7.$$

Hence, the full solution is

$$\left. \begin{array}{l} x = 5 \\ y = 1 \end{array} \right\} \left. \begin{array}{l} x = -5 \\ y = -1 \end{array} \right\} \left. \begin{array}{l} x = 7 \\ y = 3 \end{array} \right\} \left. \begin{array}{l} x = -7 \\ y = -3 \end{array} \right\}.$$

104. If we have two equations, one of the first degree and the other of the second, we can find the value of one of the unknowns in terms of the other, from the first degree equation. We then substitute this value in the second degree equation and so obtain a quadratic whose roots are the required values of the other unknown.

Example. Solve

$$x^2 + xy + y^2 = 13. \quad (1)$$

$$x - 2y = 6. \quad (2)$$

From (2) we have

$$x = 2y + 6.$$

Substitute this value in (1), thus

$$(2y + 6)^2 + (2y + 6)y + y^2 = 13;$$

or

$$7y^2 + 30y + 23 = 0.$$

Therefore

$$(7y + 23)(y + 1) = 0$$

$$y = -1 \text{ or } -\frac{23}{7}.$$

If  $y = -1$ , we have  $x = 2(-1) + 6 = 4$ , and if  $y = -\frac{23}{7}$ ,  $x = 2(-\frac{23}{7}) + 6 = -\frac{4}{7}$ .

### EXAMPLES 29

Solve the equations

1.  $x + y = 6$

$$xy = 8.$$

2.  $xy = 15$

$$x - y = 2.$$

3.  $x^2 + y^2 = 74$

$$xy = 35.$$

4.  $x^2 - xy + y^2 = 13$

$$x + y = 5.$$

5.  $x^3 - y^3 = 218$

$$x - y = 5.$$

6.  $x^2 + xy = 15$

$$xy - y^2 = 2.$$

7.  $2x - 3y = 4$

$$x^2 + xy - 6y^2 = 11.$$

8.  $3x + y = 15$

$$2x^2 - 3y^2 = 5.$$

### PROBLEMS INVOLVING QUADRATIC EQUATIONS

105. In Articles 51 and 52 [page 2577] we considered problems in which the relations between the unknown quantities, when expressed algebraically, gave rise to simple equations. We come now to problems which give quadratic equations. We have seen that a quadratic must always have *two* roots. Hence we often find, on solving the quadratic which expresses the conditions of the problem, that one of the results obtained does not satisfy these conditions. For example, if  $x$ , in our equation, represents the price of a yard of cloth, and we find from the quadratic that  $x = 6$  or  $-7$ , it is clear that the value  $-7$  must be rejected, since the cost could not be negative.

We must, therefore, always examine whether both of the roots satisfy the conditions of the question or not.

Example 1. One side of a rectangle is 3 feet longer than the adjacent side. The area contains as many square feet as the four sides contain linear feet. Find the lengths of the sides.

Let  $x$  = number of feet in the short side of the rectangle.

Then  $x + 3$  = number of feet in long side.

Hence the four sides together measure  $2(x + x + 3)$  feet, or  $4x + 6$  feet.

The number of square feet in the area is  $x(x + 3)$ . [See Art. 153 of Arithmetic, page 1442.]

Hence we have the equation

$$x(x + 3) = 4x + 6;$$

or

$$x^2 - x - 6 = 0.$$

Therefore,

$$(x - 3)(x + 2) = 0,$$

and

$$x = 3 \text{ or } -2.$$

But the length of a side cannot be negative, so that  $x = 3$  is the only value which satisfies the problem.

Thus, the short side of the rectangle is 3 feet, and the long side is  $3 + 3$ , or 6 feet.

Example 2. A farmer sells 7 oxen and 12 cows for £250; he sells 3 more oxen for £50 than he does cows for £30. Find the price of each.

Let  $x$  = price of an ox, in £'s.

Then  $250 - 7x$  = price of 12 cows, *i.e.*, the price of a cow is  $\frac{250 - 7x}{12}$ .

Also, the number of oxen sold for £50 would be  $\frac{50}{x}$ , and the number of cows for £30 would be

$$30 \div \frac{250 - 7x}{12} = \frac{360}{250 - 7x}, \text{ i.e., } \frac{360}{250 - 7x}.$$

Hence,

$$\frac{50}{x} - 3 = \frac{360}{250 - 7x}.$$

This equation, on simplification, gives

$$21x^2 - 1460x + 12500 = 0.$$

Therefore,

$$(21x - 1250)(x - 10) = 0.$$

Whence,

$$x = 10 \text{ or } 59\frac{1}{2}.$$

The price of an ox could therefore apparently be either £10 or £59½. But in the latter case the farmer could not sell 7 oxen and 12 cows for £250, since the cost of the oxen alone would be greater than this amount. Thus  $x = 10$  is the only root of the equation which satisfies the conditions of the problem. We then have

$$\frac{250 - 7x}{12} = \frac{250 - 70}{12} = 15.$$

Hence, an ox costs £10 and a cow £15.

Example 3. Find the price of eggs per dozen when two more eggs for a shilling would lower the price one penny a dozen.

Let  $x$  pence = price of one dozen eggs. Then

$$\frac{12}{x} = \text{number of } \text{doz. for } 1\text{s.};$$

$$\frac{144}{x} = \text{number for } 1\text{s.}$$

If there were  $\frac{144}{x} + 2$  for a shilling, the cost of one egg would be  $\frac{12}{\frac{144}{x} + 2}$  pence. Therefore

the price per dozen would be  $\frac{144}{\frac{144}{x} + 2}$  pence.

This is 1d. lower than the actual price. Hence

$$\frac{144}{\frac{144}{x} + 2} + 1 = x.$$

This simplifies to  $x^2 - x - 72 = 0$ . Therefore,

$$(x - 9)(x + 8) = 0;$$

so that

$$x = 9 \text{ or } -8.$$

The value  $-8$  is inadmissible. Hence the price of eggs is 9d. a dozen.

### EXAMPLES 30

1. Divide 30 into two parts, such that the sum of their squares is 458.

2. The sum of the reciprocals of two consecutive numbers is  $\frac{23}{132}$ . Find the numbers.

[Two quantities are said to be reciprocals when their product is unity. Thus  $\frac{1}{7}$  is the reciprocal of 7, since  $7 \times \frac{1}{7} = 1$ . Expressed generally,  $\frac{a}{b}$  is the reciprocal of  $\frac{b}{a}$ .]

3. A person bought a certain number of yards of cloth for 50s. If the price per yard had been 10d. less, he would have got 3 yards more for the same money. Find the number of yards he bought, and the price per yard.

4. A rectangular field is 15 yards longer than it is broad, and the area is 6,750 square yards. What is its length?

5. A journey of 209 miles would be made by a train in 16 minutes less if the speed were increased by one mile an hour. Find the rate of the train.

6. Find a proper fraction such that twice the denominator exceeds the square of the numerator by 9, and the product of the sum and difference of the numerator and denominator is 264.

7. A rectangular field contains  $1\frac{1}{2}$  acres. If it were 11 yards longer and 7 yards narrower, its area would be unaltered. Find its length and breadth.

8. Find two consecutive numbers, the difference of whose cubes is 721.

9. If the price is raised 2s. per dozen, a person gets 6 less of a certain article for a sovereign than he did at the former price. What was the original price?

10. One train travels 15 miles an hour faster than another, and takes 42 minutes less to do a journey of 63 miles. Find the speeds of the trains.

| 1. $\frac{x^2 + xy + y^2}{x^2 - xy + y^2}$ | 4. $\frac{1}{(x-y)^2}$      |
| 2. $x^2$                                   | 5. $\frac{x}{x-a}$          |
| 3. 1.                                      | 6. $\frac{x^2 - y^2}{2y^2}$ |
| 7. $\frac{1}{(x-1)^2}$                     |                             |

### EXAMPLES 26

- |                         |                            |
|-------------------------|----------------------------|
| 1. $x = 14$ .           | 4. $x = \frac{8}{3}$ .     |
| 2. $x = -\frac{2}{3}$ . | 5. $x = -\frac{ab}{a+b}$ . |
| 3. $x = -107$ .         | 6. $x = -\frac{7}{8}$ .    |

7. By simplifying the fractions the given equation becomes

$$\frac{4(21x-8)}{3(x+4)} = \frac{6(3x-26)}{2x+3} = \frac{26(x+5)}{2x+3} + 6.$$

By combining the two fractions with denominator  $2x+3$  we get

$$\frac{4(21x-8)}{3(x+4)} = \frac{44x-26}{2x+3} + 6.$$

Divide each numerator by its denominator; then

$$28 - \frac{363}{3(x+4)} = 22 - \frac{92}{2x+3} + 6.$$

Therefore,

$$\frac{4}{3(x+4)} = \frac{1}{2x+3};$$

or

$$8x + 12 = 3x + 12.$$

Whence

$$x = 0.$$

$$8. -abx. \quad 9. -\frac{1}{a^2b(a-b)}.$$

$$10. -\frac{1}{ab}.$$

### EXAMPLES 27

- |                                    |  |
|------------------------------------|--|
| 1. $x = \frac{7 \pm \sqrt{89}}{2}$ | 7. $x = \frac{2}{3}$ or $\frac{3}{2}$ .    |
| 2. $x = 1$ or $-\frac{3}{2}$ .     | 8. $x = 0$ or 3.                           |
| 3. $x = 3$ or 5.                   | 9. $x = \frac{1}{11}$ or $-\frac{1}{11}$ . |
| 4. $x = 2$ or $-10$ .              | 10. $x = \frac{3}{2}$ or $-2$ .            |
| 5. $x = -1$ or $-\frac{1}{2}$ .    | 11. $x = 8\frac{1}{2}$ or $\frac{1}{4}$ .  |
| 6. $x = 2a$ or $3a$ .              | 12. $x = 2\frac{1}{2}$ or $-4$ .           |
| 13. $x = (a+b)$ or $(a-b)$ .       |  |
| 14. $x = 1, -2$ , or 6.            |  |
| 15. $x = 2, -2, 3$ , or $-3$ .     |  |
| 16. The equation should read       |  |

$$2x^3 + 4 = 8x + x^2.$$

The solution is

$$x = 2, -2, \text{ or } \frac{1}{2}.$$

Continued from  
page 3102

## HAIRDRESSERS

In America the term "barber" is universally adopted and gloried in, but in Great Britain a certain amount of quite unjustified opprobrium has gathered round the word of late years. For this reason, "Gentlemen's Hairdresser" and "Haireutter" are now frequently preferred.

The trade of the barber is one that is subject in some measure to abuse by its being adopted, wholly or partially, by outsiders who may chance to be handy with the razor. From the honourable position of barber-surgeon of the time of Henry VIII., the barber trade sunk, in many cases, to the halfpenny shaver, of whom Richard Arkwright, the Preston barber of 1732, was one of several notable examples, although his great abilities raised him to title and fame and fortune as an inventor. The halfpenny shaver is now practically non-existent, but the penny shaver is still to be found in many places. The organised efforts of the trade societies and federations are, however, establishing three-halfpence as the minimum charge. The Incorporated Guild of Hairdressers, Wigmakers, and Perfumers (1, New Bond Street, London, W., with branches at Brighton, Liverpool, Manchester, Dublin, Birmingham, Glasgow, Edinburgh, Aberdeen, and Newcastle) and the Hairdressers' Guild of the City of London (40, Gracechurch Street, E.C.) are two trade institutions which have adopted twopence for shaving and fourpence for hair-cutting as the minimum scale they will recognise in accepting candidates for membership.

**Apprenticeship.** The system of apprenticeship is still largely, although not universally, in force in the provinces, but in London it has, to a great extent, dropped out. The rescue of the business from the abuse of unqualified persons would seem to lie in a more rigid enforcement of apprenticeship, and hence the trade societies are energetically endeavouring to restore its general adoption. The Incorporated Guild has declared its view (October, 1904) that all youths coming into the business should be indentured. The National Federation of Hairdressers (Rosedale House, Mount Pleasant, Bilston, Staffs.) and the Northern Counties Federation of Hairdressers (8, Rylands Street, Warrington), with a joint membership of over 2,000, may be taken as representative of the great barber opinion of the Kingdom, and both—as also the Incorporated Guild—have set forms of apprenticeship for the use of their members.

The term of indenture varies. The seven years system is now ignored, three years being the usual period, extended in some instances to four and five. If a premium be paid (usually £10) the youth receives in wages, taking a three years' apprenticeship, 2s. 6d. weekly for the

first year, 5s. for the second, and 7s. 6d. for the third, with food and lodging. In the absence of a premium, the payments are 2s., 4s., and 6s. respectively. Where no apprenticeship is served, boys enter the shops as latherers at 2s. 6d. weekly, for service on four evenings of the week, Saturday night, and in some cases Sunday morning, receiving meals during the periods of employment. The apprenticeship takes the form, in some instances, of a mutual verbal agreement. At the end of his term the boy goes as an improver at 10s. to 12s. indoors, and £1 to 22s. outdoors. The legal decisions as to barber apprentices seem to show that the Courts will defend the actual teaching of the trade, and not the use of the boy for domestic or menial duties. The apprentice gains an advantage here over the mere latherer.

**Assistants.** A young man really efficient in his trade and persevering has, of course, the country open to him. The village or hamlet apprentice may migrate to a small town; the small town man may venture to a larger and busier locality, or to a seaside resort "for the season," or to London. A good gentleman's hand may reasonably calculate on a weekly wage of from 25s. to 28s., and commission and perquisites. In the smaller and humbler saloon, the amount of the commission is naturally less than in the better grade shop, as the opportunities for pushing extras and sales are proportionately fewer and less remunerative individually. A common system is for an assistant to receive a percentage of one penny in the shilling on all he takes, including sales. In other cases the employer will pay a halfpenny on each singe and shampoo, and a penny in the shilling on sales. The perquisites, or "tips" from customers, are too varied and fitful for definite quotation, but may be estimated at a weekly average of 5s. in the smaller saloon, to 15s. in good class shops, and rather more in Stock Exchange and West End saloons. The hours worked are not often less than 12 per day, and 14 or 15 on Saturday. Sunday work is not general, but it has to be reckoned with, and where shops are open, the business hours are usually from 9 a.m. until one o'clock. Assistants are required to supply their own tools—razors, razor strops, scissors, etc.

**The Modest Beginning.** In the case of a steady and aspiring journeyman barber, there is good opportunity for a start in business. The amount of capital required will necessarily depend on the class of establishment to be opened. A modest barber's shop, pure and simple, may be attempted with about £25, and in this case the usual charges for attendance are 1½d. for shaving and 3d. for haircutting. Only rude saloon fittings would be requisite, and practically no

stock, the sale trade being small. After paying a lather boy or apprentice, rent, and other attendant expenses, a plain barber would expect to derive a net income for himself of £2 or £2 10s. per week. The work is hard and the hours long. Cheap labour is employed, young men often being taken who wish to pick up the rudiments of the trade without serving an apprenticeship.

**A Better-class Business.** For a saloon in which 2d. and 4d. are to be the prices in vogue, the capital necessary would be from £50 to £75. The premises would be bigger, the fittings rather more elaborate, and some outlay would be involved (say, £5) in the purchase of stock for display in the show cases attached to the walls of the saloon. Taking a three-chair shop, the provision of basins, with hot and cold water supply, mirrors and show cases would cost in material and the necessary plumbing from £25 to £40, according to the nature of the premises. A machine brush, which is now generally looked for by the public, although for sanitary reasons viewed with less favour by the trade itself, needs a further £12 or £15, and £5 must be devoted to shaving and haircutting chairs and settees. Other requisites, besides the smaller appliances, are a hot-water urn (costing about £1), and towels and cloths. A margin would, in addition, have to be set aside for proper decoration of the saloon. In a shop of this description the assistants would be paid from 12s. 6d. to 15s. indoors, and 20s. to 25s. outdoors. Brilliantine, hair brushes and combs, razors, soap, strops, collar studs, and nick-nacks constitute the sale goods, on which a profit of from 25 to 33½ per cent. is realised. The surplus, after the payment of one or two assistants, according to the volume of business, and the general expenses, averages about £3 per week.

**Sale Shop.** If a sale shop is to be opened in conjunction with the saloon, the capital required would be between £75 and £100, to cover additional fittings and increased stock. Ladies' hair nets, curlers, fancy combs, hair frames and pads, cheap perfumes, lotions, cosmetics, toilet goods, and walking sticks are amongst the goods sold, and they yield an all-round profit of about 33½ per cent.

The shampoo range illustrated in 2 is in rouge royal marble, with oak framework. Its length is 9 ft. 6 in., and its cost, complete with accessories, £50.

Many barbers' establishments in superior localities are much larger and of higher grade, both in the style and system of fitting-up, and also in the attendance given. Their proper equipment and up-keep require proportionately increased capital. The charges in such saloons are 3d. for shaving and 6d. for haircutting.

Several supplemental trades are often allied to the barber-shop, notably the sale of tobacco, the sale and repairing of umbrellas and walking-sticks, news agency, and toys. In the case of umbrella repairing especially a lucrative connection is often obtained, the margin of profit being good.

**Saloon Sanitation.** This question has occupied the attention of the public, of the trade, and of municipal authorities during the past two years or more. The matter will probably demand further handling, and its effect on the barber of all grades will then be important. The question of scientific sanitation of saloons was brought to a climax in London in 1903 by the production of a code of regulations and recommendations—at first by Dr. Collingridge, Medical Officer of Health to the Corporation of the City of London, and soon afterwards joined by the Incorporated Guild of Hairdressers, already referred to. What the financial bearing of this agitation may ultimately be upon the fittings and up-keep of barbers' saloons and upon the charges for service which they may find it necessary to levy cannot now be stated, seeing that for the present barbers may voluntarily register under this code, or may reject it, or adopt any portion of it as they personally desire. The City of London Guild of Hairdressers (inaugurated on March 8th, 1905) does not see its way to register under Dr. Collingridge's regulations, although it has adopted a code very similar in all essentials.

The National Federation of Hairdressers also formulated a sanitation code, which it preferred to that of the Incorporated Guild and the Corporation of the City of London. The ideas of each of these sections of the trade may be gathered from the following:

#### REGULATIONS OF THE INCORPORATED GUILD AND CORPORATION OF LONDON.

- (1) All shelves, fittings, and tables on which instruments are placed to be of glass, marble, slate, or other similar material.
- (2) Clean towels, etc., to be used for each customer, and a fresh piece of paper or clean linen to be placed on the back of chair or head-rest.
- (3) No general powder puffs to be used, and powder pulverizers or cotton wool to be substituted. No sponges to be used.
- (4) All hair-clippers, razors, scissors, combs or other tools, after use, to be placed in a disinfecting solution.
- (5) Razors to be wiped on paper.
- (6) Perfectly clean hair brushes only must be used.
- (7) Shaving brushes after use to be placed in a disinfecting solution.
- (8) Liquid or powdered soap or shaving cream only to be used.
- (9) Cut hair falling on the floor to be immediately swept up and removed, and floors to be cleansed daily.
- (10) No general alum crystals or blocks to be used as a styptic; but a liquid or powder applied on a towel or cotton wool, or by a spray.
- (11) The most scrupulous cleanliness to be observed in all that pertains to the business.

#### RECOMMENDATIONS.

- (a) Regular customers and subscribers should be strongly recommended to provide their own toilet articles, razors, brushes, etc., which would be exclusively reserved for the owner's use.
- (b) All cut hair and paper to be burned.
- (c) No customer apparently suffering from any skin or hair affection to be attended to, save at his own house or office, or in a private room.
- (d) Charges should, if necessary, be remodelled to enable hairdressers, etc., not only to comply with the letter, but the spirit of the above, without loss.
- (e) The operator to wear a clean white garment without pockets, sleeves fitting close to wrists, and to wash his hands before attending to each customer.
- (f) Metal combs to be used.
- (g) Machine or rotary brushes should be discarded.

**Code of the National Fédération of Hairdressers.** This is designed to deal with the structure of saloons as distinct from the internal conduct of the business, with which the Federation claims there is no need to interfere. The regulations are:

(1) Before any shop can carry on the business of a barber or hairdresser the place to be inspected and found to comply with the following:

(2) No room shall be deemed suitable where any household and domestic duties have to be carried on, or to be used as a sleeping apartment.

(3) All saloons to be adequately ventilated, and in satisfactory sanitary condition.

The probability is that the Guild and Federation will agree on a joint code embodying the main regulations put forward by each institution.

**American Practice.** The practice of the American barber differs widely from that of his confrère in the Old Country. In Great Britain shaving is only a diurnal or tri-weekly toilet necessary, which is reduced to a simple and quick process. In America the shave and its appurtenances are developed into an elaborate luxury, including face massage, scalp frictions, sumptuous sprays and shampoos, hot-towel packings, etc., so that a man who can afford it may spend hours in a barber's saloon, and pay a great deal for the service. The cheapest shave for a workman costs 5 cents (2½d.) in the States, and occupies about 10 minutes. In a low-price English saloon 12 shaves per hour is the rule, and not more than 10 minutes is devoted to hair-cutting. As the American barber does not sell goods he has no shop front, but his saloon is always elaborately fitted and equipped, and as to meet this competition no man attempts to begin business for himself with less capital than £100, the small establishment is far less in evidence in America than in the United Kingdom. Moreover, the more elaborate attendance in the States begets better workmen, who qualify by apprenticeship and examination. The American assistant is paid a commission after he has earned a certain amount—often 50 per cent. of his takings over his wage of 10 dollars in the lower grade shops to 15 dollars in the better-class establishment. A typical American barber's chair is illustrated in 1.

**Hairdressing.** "Hairdresser" is often in its application to different tradesmen a variable and variously construed term. There is some ground for the contention that a person who cuts and arranges a gentleman's hair has equal right to the title of hairdresser as he who

confines himself to the more artistic and intricate manipulation of a lady's tresses. And, in point of fact, the description is frequently adopted by the shopkeeper who lays no claim to any ability in the art of coiffure creation.

But hairdressing in the sense of artistic ladies' coiffures has long been a department distinct from gentlemen's work so far as the trades themselves understand the words. Of later years this differentiation has become more pronounced, and the terms "Court Hairdresser" and "Coiffeur de Dames," which are growing general, certainly carry conviction of the essential distinction.

**Hairdressing as an Art.** The arranging of the tresses of the living model, and the selection and adjustment of the postiche, or artificial hair, necessary and suitable to a particular style of head dress, represent the hairdresser in his finished state as a skilled worker. The building up of a lady's hair to conform to a

fashion, to suit certain specified millinery, or to meet a prescribed requirement, demands a good deal of expert labour. But "fashion is often the enemy of good taste," and therefore artistic ability and a creative adaptability on the part of a ladies' hairdresser stamp him as an artist as well as a skilled worker.

A hairdresser should be able, by a glance at the face and figure, and the nature and quantity of hair available, to decide the style and proportions of

the coiffure that is most suitable. Hence, the necessity for a study of physiognomical proportions. One face is severe and angular, and the hairdresser must seek to tone it down gracefully; another face is insipid, and he has to tone it up to express character.

One head is symmetry itself, and may be dressed proportionately; another has a bump here or a depression there which calls for skilful rectification. This low forehead must be made to look higher, and that lofty forehead must be softly subdued. In short, the oval contour of face and head, and the even grace of proportion which we call "beauty" constitute the model with which all coiffeurs must aim to conform.

**Other Important Departments.** Again, a ladies' hairdresser is expected—and, indeed, must know—how to cut, singe, shampoo, and dye ladies' hair. He must also be competent in the essential and lucrative section of the trade technically called *boardwork*. This covers the preparation of the tails or switches of hair, curls, fringes, and head-coverings (known as *transformations*), with which ladies often need to supplement their natural hair. A temporary trouble or illness, or other cause, may result in a lady's hair falling out; or she may naturally

1. AMERICAN BARBER'S CHAIR

possess but scanty locks; or to conform to a fashion, or prepare for a set function, she may require added curls, loops, fringe, or other artificial additions; and in some cases, either for temporary or general use, a partial or entire "transformation" may be required. These come within the designation of boardwork and postiche dressing, and the hairdresser should be able to suggest, take orders for, and prepare what is suitable and requisite. It should be understood, too, that a partial head-covering (technically known as a "scalpette"), or a complete wig, for a gentleman's use, come within the category of boardwork.

### The Acquisition of Proficiency.

In England, apprenticeship to ladies' hairdressing alone is practically unknown, although many of the best-known and most successful hairdressers, when they are quite proficient, abandon the other branches, and devote themselves wholly to fashionable hairdressing as specialists. The rudiments and groundwork, however, are gained during apprenticeship, which lasts for three to five years. If it be agreed that the apprentice shall have special attention devoted to his training and practice in ladies' hairdressing—the most difficult branch—a premium of from £10 to £20 is paid. A youth is often taken without premium into a general hairdressing establishment—i.e., a shop catering for both gentlemen's and ladies' attendance—for a term of from three to five years, and he is taught gentlemen's work, boardwork, and plain ladies' work, the latter covering the cutting, singeing, and shampooing of ladies' hair. The wage paid varies—5s., 10s., 15s., and £1 per week outdoors, irrespective of whether a premium is paid or not, and the amount of it. Where there is no premium the youth is expected to do more general work. To extend his knowledge and perfect himself as a ladies' coiffeur, he has afterwards to attend the several technical academics which exist for this special object.

The three teaching academics in London are:

La Société du Progrès de la Coiffure, 5, Lisle Street, Leicester Square, W.C. Annual subscription, 7s. 6d., with 7s. 6d. per annum extra for the "advanced class."

L'Académie Internationale de Coiffure, 6, Swallow Street, Piccadilly, W. Annual subscription, 5s., with a further 10s. 6d. per annum for the "advanced class."

International Hairdressers' Society, the Horse Shoe Hotel, Tottenham Court Road, W. Annual subscription, 7s. 6d., with 10s. 6d. per annum for the advanced class.

Apart from London there are similar hairdressing academics at Brighton, Bristol, Liverpool, Manchester, Newcastle-on-Tyne, Edinburgh, Glasgow, Aberdeen, Dublin, and Belfast. Of recent years efforts made to obtain the inclusion of hairdressing among the trades aided by educational authorities have been successful in London, Manchester, Glasgow, Dublin, Belfast, and Liverpool.

Proficiency in ladies' hairdressing is also acquired by private tuition and practice, apart from the work done in the shops. A fee of 5s.

per lesson is charged by well-known exponents. It is the exception to find a really expert ladies' hairdresser under the age of 24 years.

**Hair and Scalp Diseases.** This survey of the educational aspect would be incomplete without a reference to the treatment of complaints affecting the hair and scalp. Very many hairdressers are consulted by both their lady and gentlemen clientele as to troubles resulting in loss of hair, and the necessity for reliable study and experience in this section of the hairdresser's calling is daily becoming more pronounced. The College for Diseases of the Hair, 16, Brook Street, New Bond Street, London, W., was founded in 1902, and under the guidance of a skilled lecturer and a board of examiners constituted of members of the medical profession, its members are instructed and examined in hair and scalp complaints and their treatment. The curriculum is comprehensive, and the nature of the examination papers calls for considerable knowledge and study if the college degrees are to be obtained. Assistants joining the college have to pay 10s. 6d. per annum, and mastermen, 21s. The college has a technical library and laboratory.

### Assistants and their Remuneration.

A hairdresser's assistant, with fair, all-round ability—what is known as a "general hand"—receives a weekly wage of about 35s. One more skilful, but still not a specialist, commands about £2 a week. The "ladies' hand" pure and simple—and he has to be expert or he cannot be retained for this department of attendance alone—receives £2 2s., £2 5s., and £2 10s. per week. Commission is paid in all cases to ladies' hairdressers on their sales, and in most instances on the gross attendance takings also. It is an invariable custom to pay commission on singeing, shampooing, and dyeing. An assistant receiving 35s. in wages would expect to "make" at least 7s. 6d. per week in commission on attendance and sales. The higher-paid assistant would similarly augment his wage by an average of from 12s. to 15s., or more in some cases, per week. Ladies' hands also accept gratuities, which are expected to amount to as much as the commission. Assistants often receive the whole of the charge made to a customer who is attended to on Sunday, and half the sum if an order is taken at a shop and the attendance is given later than the recognised shop hours.

**Female Hairdressers.** Lady hairdressers are usually apprenticed for three years, and £10 is the premium when paid. The wage during apprenticeship varies. Where there is no premium, it is about 5s., 7s. 6d., and 12s. 6d. per week outdoors (tea is usually provided) for the first, second, and third year respectively. The apprentice should be taught boardwork, knotting, weaving, mounting, and, usually, counter work (shop sales). Her help in the shop and at boardwork is looked for as a set-off to the absence of any initial payment by way of premium. As an assistant, the wage of a lady hairdresser would average about 27s. per week, with commission (5s. or more) extra. The working hours of both male and female assistants

are usually from 9 a.m. until 8 p.m. There is a demand for lady hands in the boardwork department (apart from saloon attendance) as knotters, mounters, weavers, etc. Those willing to help in the shop in addition to doing boardwork easily obtain £1 per week when commencing, and more as they progress in ability and experience. A good many start in this way as lady hairdressers.

**Beginning Business.** In calculating the approximate cost of equipping an establishment, a clear distinction must be made between the shopkeeper who intends to run a "mixed" business (for both ladies and gentlemen), and he who aims at confining himself exclusively to the requirements and custom of ladies. Out of London, shops in the latter category are not often met with, but there is now a tendency both in and out of the metropolis, in certain districts, towards specialisation in this way.

The beginning of a moderately-sized business for ladies should be accomplished with an initial outlay of about £75 to £85. This estimate would apply to a business that is to be done on a floor above another establishment. It is customary in this class of concern for the beginner to start with some personal connection. The main fittings for one saloon would include a lavatory basin, with hot and cold water supply which would suffice for the requirements of two workmen for shampooing, two or three dressing tables with mirrors, two hair dryers, three curling iron fixtures, one child's haircutting chair, three easy-chairs, one lounge, three dressing chairs, two ordinary chairs, linoleum and rugs for the floor, plumbing and gasfitting, hot water arrangements, etc., with show cases, including a couple of wax figures, and stock.

**Fittings.** When a shop with a saloon at the back or upstairs is taken, and window fittings, shop cases, etc., have to be provided, the necessary capital would be at least doubled—say £150 to

£200. Amongst the leading items of expenditure would be: shop window fittings, about £20; counter, £5; shampoo basins for two chairs, including mirrors, £10; dressing table, with mirrors, £5 5s.; three ladies' hairdressing chairs, £1 10s. each; two ordinary bentwood chairs, 15s. each; settee, at £1 per foot, say, £6; one or two hair dryers, £3 10s. each; two wax figures, £6 6s. each; curling stoves, 8s. 6d. each; hot and cold water fittings, with cistern and boiler, say, £10 to £12; waste pipes and plumbers' work in fixing above, say, £3 to £5; show-cases for goods, say three at £5 each; linoleum and mats for floors, shop, saloon, and staircase, about £6. Smaller lines would be: linen (towels and gowns), hair brushes and combs, curling irons, etc., about £8. In addition, £50 or so would be necessary for the purchase of a stock of hair, perfumery, toilet articles, and the usual trade sundries.

If what is generally termed a "hairdressing business" is to be started—i.e., for ladies' hairdressing, cutting, singeing, and shampooing, with a gentleman's saloon attached—the fittings and other necessities for both rooms, with

shop front, would need a capital of, approximately, £200 to £250 for a small but decent average establishment. The additional fittings for the gentlemen's saloon would include a hairbrushing machine for two chairs, with set of brushes about £12 12s.; shampooing stands, £3 10s. each; saloon chairs, say, £4 10s.; mirrors, etc. Obviously, the beginner must exercise care in selecting, for the particular class of business he contemplates opening, a neighbourhood which embraces the right sort of clientele. It is apparent, for instance, that a business confined to ladies' attendance would be misplaced, and doomed to failure, if commenced, say, in a purely commercial district in which the lady residents are few, or not of the required social position.

# SPECIAL HOME APPOINTMENTS

Police Court. Factories and Mines. Prisons. The High Court. Museums.  
Patent and Audit Offices. Board of Education. Women Typists

By ERNEST A. CARR

THE present article is devoted to a consideration of certain special appointments in Government departments other than those already described.

**Home Office Posts.** Foremost among such offices, in respect alike of the variety and the responsibility of its work, is the department controlled by the Secretary of State for Home Affairs. The main functions of that official himself are defined as "the maintenance of the King's peace, the enforcement of rules made for the internal well-being of the community, and the exercise of the prerogative of mercy." These duties include general powers of control over all police bodies and courts of summary jurisdiction, the support of a special civil force in London—the Metropolitan Police—the State inspection of factories and mines throughout the kingdom, and the maintenance of our local and convict prisons. For their performance the Secretary of State is provided with an enormous staff—clerical, technical, and executive.

The Metropolitan Police force, although in strictness a Government body, is paid chiefly from local rates. It was, therefore, included in the municipal section of this course, and will be found fully described on page 1406. Another special branch of the Home Office—the Metropolitan Police Court Service—may be dismissed in a few words, as the Home Secretary now reserves its clerical appointments (£120 to £650 a year) for members of the Second Division who are recommended by their chiefs. Ushers and messengers in this service owe their posts to private influence brought to bear upon the Secretary of State.

**Factory Inspectors.** To protect the workers in factories and workshops from excessive hours and unhealthy conditions of labour, a small body of experts, under the Home Office, is constantly engaged in visiting these centres of industry, and in warning or prosecuting the offending firms. The staff numbers about 150 in all, including assistants and lady inspectors. Every candidate for this service must first be nominated by the Home Secretary, and is then required to pass an examination (which is most often mildly competitive) in certain specified subjects. Forms of application for nomination can be obtained from the private secretary to the Secretary of State, Home Office, S.W. It is of importance to note that applicants are selected according to their practical qualifications rather than the private influence they may be able to secure. Proofs of an intimate knowledge of factory or workshop administration, for instance, coupled with high testimonials of ability and character, are the likeliest passports to a nomination.

For male inspectors of factories, the age limits are 21 and 30, with an extension to 38 in favour of inspectors' assistants and of candidates who have had seven years' practical experience in a factory or workshop. Candidates must qualify in English composition and précis writing, and in arithmetic. They may also select any four in the following list of optional subjects, and must pass in three at least:

1. English Literature.
2. English History.
3. General Modern History.
4. French, German, or Italian.
5. Mathematics.
6. Economics and History of Modern Industry.
7. Chemistry.
8. Physics (including Mechanics).
9. Mechanism and Industrial Machinery.

The duties of a factory inspector are technical and fairly arduous, involving irregular hours, occasional night work, and a good deal of travel. They are rewarded with a salary of £200 a year, rising by £10 annually to £300, and afterwards to £400, with travelling and other allowances. There are excellent prospects of at least £500 a year, and possibilities of £700 and upwards.

Lady inspectors are admissible between the ages of 21 and 40 years. Candidates must pass an examination in English composition, arithmetic, sanitary science, and the law relating to factories and workshops. They must also satisfy the examiners in either elementary physics and mechanics, chemistry, or the history of industrial and social legislation. Successful candidates are appointed at £200 a year, with £10 increments up to £300, and a fair prospect of £100 more. Like other women civilians, they must resign their posts on marriage. The staff is a small one, and vacancies arise but seldom.

Assistants to inspectors are selected from among men with a practical knowledge of factories, and are generally required only to pass a qualifying test in simple English subjects and the elements of factory law. The limits of age are the same as for women inspectors. These appointments are of small value in themselves, carrying a salary of £100 a year, with £5 rises up to £150 only. Their chief attraction lies in the chance they offer of obtaining a nomination for the post of inspector. There are no female assistants on the staff.

**Inspectors of Mines.** For men of ability, with a sound expert knowledge of coal-mining, and not less than 23 nor more than 35 years old, the mine inspection staff of the Home Office affords a most promising career. The nomination of the Home Secretary, which is essential for this service, is reserved for candidates who, within the past five years, have spent

at least two years underground in a coal-mine. The examination scheme is simple, but includes theoretical and practical acquaintance with coal mines and mining, and a knowledge of metalliferous mines. On appointment as assistant inspector an officer receives £300 a year, rising to £400. There is a good prospect of an inspectorship at £600 to £800 a year, and a considerable proportion of posts in either grade carry extra allowances not exceeding £100.

**The Prison Service.** The control of the English local and convict prisons is vested in the Prison Commission, a special department of the Home Office. For admission to this service the Home Secretary's nomination is imperative. It is readily accorded to suitable candidates, and should be sought by means of a printed form of application to be obtained from the Prison Commissioners, Home Office, S.W.

For prison clerkships the age limits prescribed are 18 and 22, but clerk warders are eligible until 30. Vacancies are filled by competitive examinations in the ordinary English subjects, book-keeping, indexing, and digesting returns into summaries. These officers are liable to serve at any prison in England and Wales. Their pay starts at £70, and rises to £300 a year, beyond which latter sum there are scanty prospects.

**Warders and Matrons.** Candidates for subordinate positions in the English prison service are selected after passing an educational test of an elementary character. For the post of assistant warder or male nurse in a local prison, and for that of attendant in a State inebriate reformatory, the examination is in writing (including copying manuscript and spelling) and arithmetic (first four rules, money, and avoirdupois weight). The civil guard of convict prisons, and matrons and assistant matrons in all penal establishments are examined only in reading, writing and arithmetic (simple addition and subtraction). The holders of second class Army certificates are exempted from these tests. The limits of age are—for male candidates, 24 and 42; and for women, 23 and 40. Applicants of either sex must be healthy, well-developed, and active, of strictly sober and temperate habits, and of unquestionable character.

The minimum stature for the male staff is 5 ft. 7 in., except for trained nurses, who are admissible if 5 ft. 5 in. in height. Men who have served in the Army or Navy are readily accepted, provided their record is good. They must have obtained either "Exemplary" or "Very Good" characters on discharge, and it is officially stated that "one entry for drunkenness during the last six years of their service, and more than one such entry during any earlier service," disqualifies them from receiving an appointment. Those discharged as non-commissioned or petty officers are preferred for the local prisons and inebriate reformatories; and preference is often given to applicants with a good knowledge of some useful trade which they can teach if required.

Selected candidates are appointed for a year on probation, during the first four months of

which term they undergo instruction in their duties, usually at a prison where there is a training school for officers.

The numbers and rates of pay of male and female warders (or matrons) are shown in the following table. In addition to the salaries there given, these officials are entitled to free quarters—or an allowance instead—uniform, and medical attendance:

| PRISON WARDERS, ENGLAND AND WALES |       |            |         |            |  |
|-----------------------------------|-------|------------|---------|------------|--|
| GRADE.                            | MALE. |            | FEMALE. |            |  |
|                                   | No.   | Pay.       | No.     | Pay.       |  |
| <i>A. In Local Prisons:</i>       |       | £          |         | £          |  |
| Chief Warders ..                  | 55    | 93 to 150  | 3       | 100 to 120 |  |
| Principal Warders ..              | 126   | 85 .. 93   | 16      | 70 .. 80   |  |
| Warders ..                        | 590   | 70 .. 78   | 113     | 55 .. 70   |  |
| Assistant Warders ..              | 847   | 60 .. 68   | 224     | 45 .. 50   |  |
| <i>B. In Convict Prisons:</i>     |       |            |         |            |  |
| Chief Warders ..                  | 5     | 115 to 195 | 1       | 95 to 145  |  |
| Principal Warders ..              | 60    | 93 .. 105  | 4       | 70 .. 85   |  |
| Warders ..                        | 133   | 83 .. 90   | 5       | 60 .. 75   |  |
| Assistant Warders ..              | 417   | 40 .. 83   | 16      | 50 .. 65   |  |

Similar conditions of employment prevail in the prison services of Scotland and Ireland, but with differing limits of age. Detailed information concerning these can be had on application respectively to the Prisons Commission, Edinburgh, and the Prisons Board, the Castle, Dublin.

**Clerks in the High Court.** To aspirants who are debarred by their training from first-class appointments, clerkships in the Royal Courts of Justice should offer considerable attractions. The duties are light, the salaries fairly good, and the prospects excellent; while the staff is so large that from 20 to 30 vacancies arise every year. Yet, for some unexplained reason, these posts attract but little notice—probably owing to the natural but mistaken idea that some legal knowledge is requisite for an appointment. As a fact, candidates who secure a nomination for a third-class clerkship—the grade in which appointments are generally made—have only to pass a non-competitive test in copying manuscript, indexing, and digesting returns, in addition to ordinary English subjects. The right of nomination is vested in the Lord Chancellor, and to a lesser extent in the Lord Chief Justice, the Master of the Rolls, and the President of the Probate Division. Persons seeking the Lord Chancellor's nomination should apply to his private secretary at the House of Lords, stating their age (which must be between 20 and 30) and their qualifications for an appointment, and enclosing copies of testimonials. From among such applicants a selection is made when a vacancy occurs.

Third-class clerks in the High Court start at £100 a year, advancing by £10 yearly to £200. On entering the second class they receive £250, with £15 increments to £400; and salaries in the first class progress by £20 from £500 to £600. The proportion of these superior posts is high, and there are chances of still further advancement.

**Museum Appointments.** Unlike the majority of Civil Service departments, which have little save clerical work to offer, the State museums afford thoroughly congenial employment to the student of letters, art or science. This incentive, rather than the salaries paid, attracts to the British and the Victoria and Albert Museums men of an unusually high level of attainments, many of whom are real scientists or scholars.

Vacancies in this service are filled by limited competition. Candidates for assistantships in the Victoria and Albert Museum are nominated by the President of the Board of Education, whilst those seeking a post in the world-famous institution at Bloomsbury must obtain a like favour from one of its principal trustees—namely, the Lord Chancellor, the Archbishop of Canterbury, or the Speaker of the House of Commons. The age limits are, in the first case, 18 and 25; and in the other, 20 and 25.

For the British Museum, which has by far the larger staff, the examination scheme varies with the particular requirements of every section, English composition being the only "Constant." In the science departments the competition rests mainly on practical and written tests in zoology, botany, geology, or mineralogy, according to the post in view. For some branches Greek, Latin, French, and German are prescribed, in addition to a difficult antiquarian, technical, or art subject. Others exact two of the above languages supplemented by an Oriental tongue.

Candidates who pass this trying ordeal are appointed at £150 a year, rising to £500, with chances of eventually controlling a department of the British Museum at a maximum salary of £800, or of holding deputy rank at £650. Having regard to their acquirements, these figures can hardly be regarded as adequate.

The standard for entrance to the Victoria and Albert Museum is a little less severe, but includes two languages, drawing, and either an art subject or several natural sciences. These assistants are less liberally paid than their colleagues at Bloomsbury, starting with £120 and having to reach the grade of assistant-keeper before rising to £500.

**Patent Office Examiners.** The valuable post of assistant examiner in the Patent Office is readily accessible to any student between 20 and 25 years of age who possesses a thorough theoretical and practical knowledge of the physical and mechanical sciences. The work of these officers consists in examining and indexing the specifications and other documents submitted to the Patent Office by persons who are seeking patent rights. They are paid £150 a year on appointment, and receive a £15 increment yearly up to the substantial income of £450. There are also good chances of promotion to the grades of deputy-examiner and examiner, with maxima of £550 and £700 respectively.

Assistant-examiners are appointed on the results of open competitions, held at intervals of about a year, for a considerable number of vacancies—usually from 12 to twice that number. The examination fee is £5. At these contests no subjects are obligatory, but a candidate who failed to score fair marks—in each of the science papers at least—would have no chance of success. The scope of the examination is indicated by our table of marks, which relates to a competition among 109 aspirants for 20 places. It should be added that the chemistry required is chiefly inorganic, that the physics includes hydrostatics, heat, light, and sound, and that in these subjects and in electricity and magnetism there is a practical examination.

### Examiners in the Audit Office.

As was mentioned in the last section, vacancies among the examiners in the Exchequer and Audit Office are filled by means of the joint open competitions which serve also to recruit certain junior appointments in the Admiralty and the War Office. The subjects of examination and limits of age are identical for all these posts, and will be found on pages 3195-6. The same scale of salaries is also prescribed—namely, £100 a year for the probationary period of two years, and thence by £10 yearly to £200 and by £15 to £350. Although the examining staff of the Exchequer and Audit Office have some prospect of reaching £500 or more, there are relatively few superior posts. Nevertheless, appointments of this class are greatly preferable to the Second Division or Excise. They are not very keenly contested, a recent examination for six places attracting only 38 competitors.

Examiners are liable to serve at any station at home or abroad where the audit of Government accounts is carried on; and the chance of a transfer for several years to Portsmouth, Plymouth, or elsewhere, is usually welcomed as a relief from the tedium of London duty. Foreign billets offer the further attraction of special pay and allowances, and are popular with the staff.

**The Office of Woods.** The open competitions occasionally held for second class clerkships in the Office of Woods offer an assured prospect of at least £400 a year to candidates who are declared successful. Only those persons are eligible who have had three years' experience in a solicitor's office, and whose

age is between 19 and 23. The examination includes the usual English papers, Latin, and two important legal subjects—the elements of conveyancing and of the law of real property, especially that of landlord and tenant. Second class clerks start at £100 a year and rise to £275. On entering the first class they advance by £15 yearly from £300 to £400, and there are chances beyond this grade.

**The Ecclesiastical Commission.** Junior clerkships in this office are awarded on the results of competitions held at intervals of a year or more, to which all candidates between the ages of 18 and 22 are admissible. The initial and maximum salaries are the same as in the Second Division, but the increments and the prospects of promotion are somewhat better. Algebra, Latin, and a modern language are the only special features of the examination scheme.

**Board of Education Inspectors.** The man or woman who obtains an appointment as junior inspector under the Board of Education thus secures one of the best openings that the national service offers. Unlike most Government servants, these officers are not required to pass an entrance examination of any sort. Appointments are made on the nomination of the President of the Board from among candidates between 23 and 35 years of age, who are usually university graduates in honours with a good knowledge of the theory and practice of teaching. It is officially notified that in the selection of inspectors weight is given to “the possession of (a) a university degree in honours, or other like distinction; (b) a university certificate or diploma in teaching; (c) the elementary teacher’s certificate of the Board of Education; (d) qualifications in special subjects.”

Candidates seeking the President’s nomination should apply to the Secretary of the Board of Education, Whitehall, S.W., on a form provided for the purpose, and should accompany their application with not more than six testimonials, one or more of which should relate to their knowledge of teaching.

It is not surprising that the appointment of junior inspector is popular with college graduates of either sex. The salary is the same for men and women—namely, £200 a year, with £15 yearly increments to £400; but whereas this represents the maximum ordinarily attainable by women inspectors, their colleagues of the sterner sex have practically assured prospects of an inspectorship at least, the reward for which is £400 a year, rising by £20 to £800. Junior inspectors are entitled to six weeks’ annual leave, increased after ten years’ service to eight weeks. They are allowed full travelling expenses, including first class railway fare and a

personal allowance of £1 a night during absence from home, and their position is generally an assured and pleasant one.

**Women Typists.** Many Government departments now include a small permanent staff of female typists, who become entitled to the benefits of the marriage gratuity and pension schemes like other women civilians. Their pay is certainly not excessive, even in the present congested state of the feminine labour market. Starting at 18s. weekly, the typist receives 19s. in her second year, rising afterwards by 2s. yearly to 25s., and, on promotion to the grade of superintendent, to a maximum not exceeding 35s. Beyond that figure there are no possibilities of advancement.

Candidates must first be nominated by the head of the department they wish to enter, and must then pass either a competitive or a merely qualifying test in writing, spelling, copying MS., simple arithmetic, and typewriting. For the last subject a Remington machine (No. 3 or No. 5) is usually employed. Shorthand may be added if it is required by the office which the candidate has in view. From 40 to 50 vacancies occur yearly in the various offices. The examination fee is 1s.

**A Word to Students.** Our survey of the home service being now concluded, we venture to add a hint or two addressed to the young aspirant for a State career who is obliged—as so many are—to enter in a subordinate grade at the outset. For such a student the importance attaching to the first two or three years of his service is incalculably great. Unless by the slow and uncertain way of promotion, it is generally during those years that he must win a higher appointment, if at all. Inability to grasp this vital fact is mainly responsible for the failures and disappointments which are frequent in this as in every other calling. The newly-appointed civilian, confident in his abilities, suffers himself to rest on his oars a little. The months slip past unnoted, and link themselves into years—precious and irrevocable years; and when at length the effort of study is resumed, all is out of gear—the habit of strenuous work is lost, one’s knowledge is dim and blurred, and the question of age limits has become suddenly menacing. So, once more, “A lost chance flies owre sea.”

From this signal danger there is but one way of escape—the heroic commonplace of steadfast and unremitting toil from the moment the student gains his first footing in the service until he attains the goal of the higher appointment he covets. The man whose resolution is thus proof against the temptation to relaxed effort is he who ultimately “arrives.”

*National Service concluded*

# MINING MINERAL MASSES

Stoping Wide and Narrow Veins. Winding Minerals  
and Water. Mining Plans. Shafts for Coal Mining

By D. A. LOUIS

**OVERHAND** stoping is just the reverse of underhand stoping. The work is commenced like a raise, or, better still, at a winze. As soon as the excavation is of sufficient height, a timber platform supported on stulls is fixed up for the men to stand on, and for the accumulation of waste. Where the vein is narrow a good bit of waste rock is broken down in order to make the excavation large enough to work in. Fig. 66 shows work in a narrow reef with stulls (A) and planks supporting waste. B is the stope. The rock is worked away in *step* fashion—that is, a block of ore is worked out at each end of the first excavation, then another block is removed from overhead at the centre, and two more blocks are removed from the ends of the first stage, and these form the second stage, while a third stage is started at the centre, and so on. The waste is allowed to accumulate under the feet of the miners, and forms a sort of pyramidal heap; it is kept well up to the working face, and furnishes a foothold for the miners. Fig. 67 shows a group in an overhand stope on a flat vein in Cornwall. Where the vein is wide

and all mineralised, so that there is not sufficient waste, temporary platforms are erected for the miners to stand on. The valuable material is broken down at the same time as the worthless vein rock, but care is taken that they do not get mixed; in fact, the ore is sorted out and thrown into shoots, which are provided for the purpose, and which emerge at the level below. In 68 two shoots are seen with tram below, one ready for charging. They are closed with movable boards, so that the ore can be withdrawn whenever there is a waggon available, and vertical passages or openings, called *passes*, in connection with the shoots, are kept open in the waste at convenient distances apart, and securely timbered. The excavations of an overhand stope has the appearance of a very rough kind of staircase looked at from below. In overhand stoping, it will be observed that neither ore nor water has to be lifted from the workings.

**Modifications of Stoping.** Masses of ore, and also very wide veins, are worked by modifications of the stoping process—that is, the

ore is removed in a series of cuts, some provision being made for filling in the excavation as the ore is removed, unless the ground is particularly strong and can be safely left unsecured. Fig. 69 illustrates a method of working a *mass* of iron ore in Cumberland. It will be seen that it is a modified overhand stope, the deposit being worked away in horizontal slices 6 ft. high, the empty space being stowed with rubbish sent down from the surface. Some men are shown levelling this *packing*, while others are busy breaking down ore, which is sent down the pass and loaded into trucks in the level below. Both transverse and longitudinal sections are given, while the letters indicate the character of the country. Notice how the fault cuts off the limestone and iron ore and brings in the coal measure shales.

Fig. 70 sets forth the method of working a wide vein in a mine in Hungary. Here the levels A, B, 133 ft. apart vertically, are connected by winzes (g) at intervals of 72 ft. One winze is shown timbered and is kept open as a pass for the ore and a ladder-way for men; the other, which serves for ventila-

66. WORK IN NARROW REEF  
WITH STULLS

tion, is filled in, as are also the worked out areas as work progresses.

The section on AB shows that the ore is removed in a series of horizontal longitudinal cuts, the excavations being duly timbered; the various cross-sections marked 1st, 2nd, 3rd, 4th, and 5th stage respectively, show the order in which the cuts are made, owing to the dip; cuts 2 and 5 are only half the size of the others.

**Mechanical and Power Drills.** In driving levels and cross-cuts, and frequently in stoping also, hand drilling gives way to the more expeditious mechanical drill, or to power drills, to which we have already referred. Fig. 71 shows a rock drill set to work in a stope. One miner is working the drill, the other is directing a spray of water on the hole to prevent injurious dust getting into the air. The drill is being worked by compressed air, which also serves to drive the spray from the water barrel. The flexible air-pipes are shown.

The valuable mineral is hence removed from its original position in the ground by one or other

of the methods mentioned or modifications of them—that is, as far as deposits of the descriptions dealt with are concerned. And the broken ore is generally roughly sorted in the mine, and reaches a level by a pass or by windlass, as the case may be, and gets to the shaft, almost invariably, in waggons or underground tramways. At the shaft, in small mines, it is tipped into an ore bin, or *plat*, and there awaits the mine bucket, or kibble. In larger mines and in inclined shafts a skip is used, and in still larger ones a cage is frequently employed, which takes the loaded waggons themselves to the surface.

**Kibbles and Skips.** These appliances are made in a variety of forms, and of many different sizes, of which, however, an example or two only can be given here. The *kibble* shown [72] is a riveted sheet-iron or steel bucket, strengthened by bands and suspended by strong chains and special coupling links to the *capping* at the end of the winding rope, which is generally made of the very best steel wire, and which passes over the pulley in the head-gear at the top of the shaft to the winding engine. The kibble is lowered when required to a level, the ore is charged in from the hopper, and then raised to the surface. The skip [73] is a rectangular sheet iron or sheet steel box, with an inclined bottom and a hinged door for emptying it. It runs, as all skips do, in or on guides; the guides are wooden bars attached to the buntons, or dividings in the shaft. When the skip reaches the surface, the banksman,

68. ORE SHOOTS IN A LEVEL (TRANSCAAL MINE)

or lander, closes the door over the shaft, brings a tram waggon into position, lowers the skip over it, knocks up the bolt retaining the hinged door, and the contents fall out into the waggon. Sometimes, however, a self-discharging skip is used, and one form of this appliance is shown [74]. In it the bow is pivoted at the bottom of the skip—which in this case is flat—and during the upward journey the full skip keeps upright until it reaches the surface, when the front wheels, having a narrower tread than the back wheels, pass between the main guides on to the supplementary rails. The back wheels follow their course on the main guides, the bow turns on its pivots, consequently the back of the skip is raised above the front part and the contents fall out of their own accord.

**Cages.** Fig. 75 shows a form of single-decked cage. It is made of steel or iron and consists of a framework, with a floor with rails for the waggons, and a cover above to protect men when travelling in it, the sides are protected with sheet metal to the height of the loaded tub. Shoes are provided for running on the guides in the shaft, and a catch serves to prevent the waggons from slipping out. The landing dogs, cage props, or keps, are four in number, and are placed at the surface and at each level where the cage stops. As the cage passes up they are pushed aside, but fall forward again and stop the way as soon as the cage is drawn above them. The cage is then lowered by the engine man, and it rests on the keps until the

67. MINERS IN OVERHAND STOPE (KING EDWARD'S MINE) *Burrow, Cambores*

## MINING

waggons are changed; then the cage is raised clear of them, the banksman draws them out by means of the lever, and holds them back

or less inclined like the levels, vein. The

towards the spectator, as, they follow the dip of the ground that has been stoped is indicated by shading, while the unshaded part, traversed by levels and winzes, shows the ground that has been developed and blocked out ready for extraction. The occurrence of cross-courses and dykes is also indicated. Then, by having assays made of the ore from different spots in the mine, and noting the results in the right position on the plan, a valuable record of the richness of the mine is obtained and the position of the ore-shoots are usefully indicated. It will be noticed that the newer and deeper workings of this mine are planned more systematically than the older

### 69. METHOD OF WORKING A MASS OF IRON ORE IN CUMBERLAND

(From a diagram of the Institution of Mining Engineers)

A. Coal measures B. Limestone C and D. Shales E. Slate rock F. Iron ore G. Rubbish H. A fault

until the cage has passed. There are four keps to hold a cage, set in pairs, each pair being keyed to one shaft, while arms and a link connect the pairs of keps and ensure the moving backward or forward simultaneously. We have now landed our ore at the surface and must leave it there for the present. But before passing on to bed or seam mining, we may give some notion of the general character of a metal mine, and we are indebted to Mr. R. E. Commins, of Messrs. John Taylor & Son, for the mine plan and section now to be considered.

**Mine Plans and Sections.** One of the most important duties of a mine manager is to see that accurate surveys are made of the mine workings and are properly and carefully recorded, not alone in the proper books but also in plans and sections that should always be kept up to date. These should include a ground plan, a working plan, a longitudinal section and a transverse section [76]. The surface arrangement, including various buildings and old open cast workings are indicated in correct position on this section; but the underground workings are represented as if a section of the ground was cut away and a side view of the mine exposed. All the vertical shafts, the stopes, and the position of ore courses are correctly shown; but the levels, inclined shafts, and winzes are projections and have a false appearance; while cross-cuts appear merely as openings, indicated by the little black marks in the levels. The levels are shown by the horizontal lines, and their distance apart is distinctly indicated.

The other lines show the shafts and winzes. Hume's shaft and Ogle's shafts are inclined shafts. Taylor's and Tennant's shafts are vertical to the 1,450 ft. level and the 1,250 ft. level respectively; all the winzes are more

and upper workings. Fig. 78 is a transverse section at Ogle's shaft, and it shows the inclination of the shaft following the dip of the lode. The levels merely appear as openings as they are seen only on end, whilst with the shaft sunk on the lode no cross-cuts are necessary, as in the case of Ogle's shaft. But 600 ft. away at the surface in the direction of the dip Taylor's shaft is shown; this is vertical and intercepts Ogle's shaft at the 1,450 level, a vertical distance of about 1,090 ft.; and for this to reach the lode at any other point cross-cuts are required, as indicated by the dotted lines, at the 500, 800 and 1,150 levels, and the cross-cuts, like the

70. MINING A WIDE VEIN

shaft, are correctly represented on this section. Fig. 77 is a working plan and represents the appearance a mine would present looked at from above and supposing the upper ground to be transparent. It gives a correct view of the windings and character of the levels as they follow on the strike of the lode. But the inclined shafts and winzes are projections and have a false appearance, while the vertical shafts A and B appear as mere openings. If the vein were vertical the levels would be immediately under each other; but, as the vein in the present instance has a dip to the west, each level appears on the plan a little to the west of the one above it. It will be seen that with these drawings of a mine the relative and actual position

Barrow, Cambridge

71. ROCK DRILLING IN A STOPE WITH THOMAS' WATER SPRAY TO PREVENT DUST

of any part of the mine can be easily ascertained.

#### Bed or Seam Mining.

We may now pass on to the consideration of the working of bedded deposits that necessitate the employment of operations conducted underground. The chief mineral wrought in this manner is coal. As in the case of a vein, wherever it is possible, seams are worked by preference through day levels, but it does

not frequently happen that seams are so situated as to permit of this economical method of working. The writer has visited coal mines in America which enjoy this advantage, and consequently can produce coal at a very low price; but that is exceptional and shafts have, as

a rule, to be resorted to in seam mining. The sinking of a shaft for working a bedded deposit is generally a far more troublesome undertaking than for vein mining. In the latter case, the country is, in most cases, fairly strong and uniform in character, while in the case of bedded deposits, beds of very variable character and consistency have frequently to be passed through, and so, to keep back the looser strata, these shafts have to be made very strong, while to keep back water, in many cases a continuous metal lining is required. Moreover, in bed mining—coal, for instance—a large quantity of comparatively low-priced material has to be extracted to make the work remunerative, whereas in vein mining the reverse is usually the case. Again, in coal-mining a very large quantity of fresh air has to be artificially kept in circulation to provide the miners with a wholesome atmosphere and to diminish the risk of explosions. Hence it is that these shafts have to be capacious and strong, and to fulfil these requirements circular shafts are usually adopted, although rectangular, polygonal, or even elliptical shafts are sometimes favoured. The circular shaft—under the prevailing conditions—is cheaper to sink, provides plenty of room for the cages or appliances used for the extraction of mineral, and yet can also accommodate water and other pipes, and still leave plenty of free space for the circulation of air.

**The Site for a Shaft.** In selecting the site of a shaft, various points must be considered. It should be as near the centre of the area as possible, unless the occurrence of faults, or the question of dip, etc., makes this position undesirable. It should, if possible, be near railway communication, and the ground around must be suitable for laying out sidings, and also for the erection and accommodation of the various surface arrangements. The proximity of a waterway and a good supply of water should

72. KIBBLE,  
WINDING ROPE,  
AND PULLEY

73. SKIP WITH  
DISCHARGING GUN

## MINING

be considered, while sandy, swampy, mossy, and bad lands generally should be avoided as far as possible.

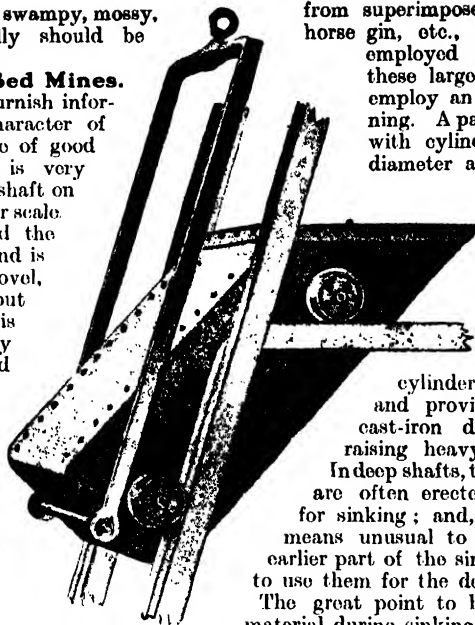

### Sinking Shaft for Bed Mines.

The preliminary borings furnish information concerning the character of the country, and if it be of good character, the operation is very similar to the sinking of a shaft on a vein mine, but on a larger scale. Head gear is erected, and the upper soil and loose ground is removed by pick and shovel, wooden framework being put in to secure the ground. This framework consists usually of curbs or rings constructed of wooden segments bolted together [A 79] and kept a proper distance apart by punch props, B, and held together by stringing deals, C, supported by baulks, D, above and packed behind with lining deals or lagging, E. When solid rock or *stonehead* is reached, the temporary wooden supports are replaced by brickwork, and carried some distance above ground, to provide accommodation for the waste. It is also necessary to see that proper foundations are available for the head-gear and engine-house, and if solid rock be not available, solid brickwork must be built round the top of the shaft, in which archways are provided for pipes, etc.

A strong frame is placed across the top of the shaft and boarded over, except an opening in the centre, over which is placed a rolling bridge arranged to run on rails, so that it can be made either to cover the shaft or to leave it open. This opening is fenced round, the sides and back being fixed, the front attached to the rolling bridge, while inclined boards, or *striking deals*, are fixed below the opening to guide the hoppit, kibble, or bucket. Sometimes hinged doors are used to cover the shaft instead of the rolling bridge.

### Raising and Lowering Material.

For raising the broken material from the sole, any one of the devices,

74. AUTOMATICALLY DISCHARGING SKIP

75. SINGLE-DECKED CAGE (Holman Bros., Camborne)

from superimposed platforms, windlass, horse gin, etc., to an engine, may be employed if expedient, but for these larger shafts it is better to employ an engine from the beginning. A pair of horizontal engines with cylinders 16 in. to 20 in. in diameter and stroke of 3 ft. will

serve the purpose. They should be steady running, easily controlled, and provided with powerful brakes; moreover, they are supplemented by a pair of steam capstan engines with 12 in.

cylinders and stroke of 2 ft., and provided with a reserve of cast-iron drums for lowering or raising heavy weights in the shaft.

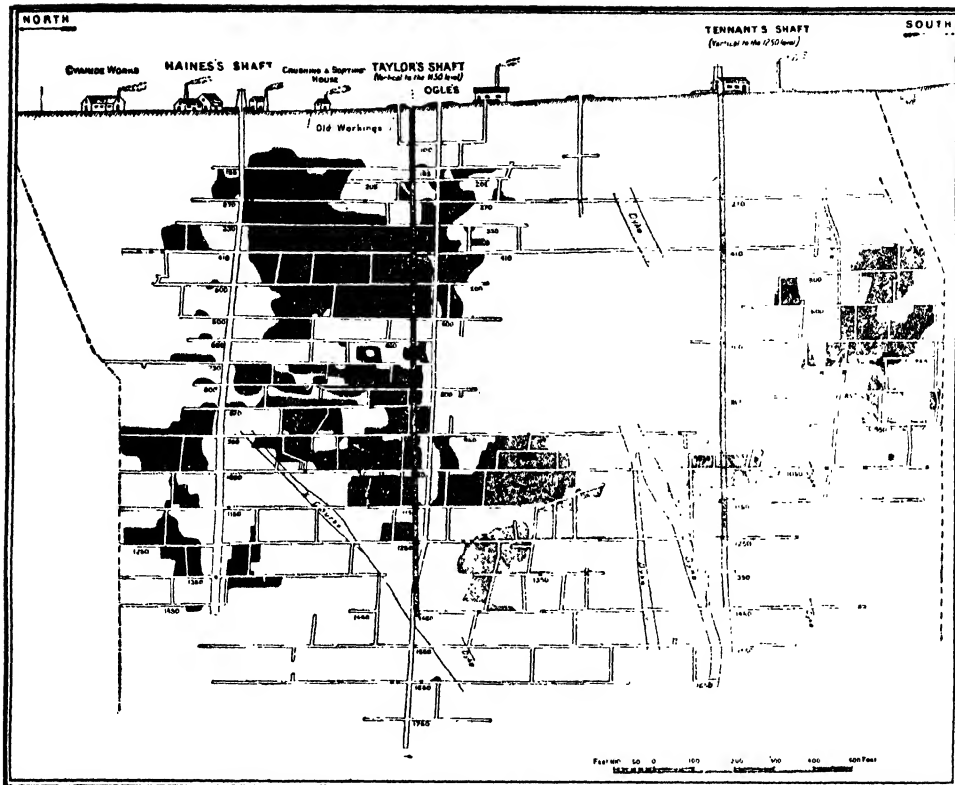

In deep shafts, the main winding engines are often erected beforehand and used for sinking; and, anyway, it is by no means unusual to erect them while the earlier part of the sinking is in progress, and to use them for the deeper sinking work.

The great point to be observed in winding material during sinking is to have it as steady as possible, so as to avoid the swinging or twisting of the hoppit or kibble and the projection of any of its contents to the bottom of the shaft. Steel wire ropes are used, lock-coil ropes being the best, as they run smoothest. Other round ropes are also used, but must not twist; flat ropes sway too much, and are more expensive. At

the end of the rope there are three or four yards of heavy chain, known as a *bull chain*, to which the hoppit is attached from a swivel spring-hook.

### Pumping Water.

Some arrangement for dealing with water, if encountered, is required, and it generally takes the form of a pumping engine at the surface, with pipes leading down and up the shaft; this is frequently supplemented as required by sinking pumps and pulsometer water lifters. But if the quantity of water be small, it may be kept down by winding in the kibble, or in a special water tank or bucket, of which there are many patterns. One shown [80] consists of an iron or steel vessel with bows above and a valve opening upwards below. This is opened by

76. LONGITUDINAL SECTION OF A WORKING METAL MINE

77. WORKING PLAN OF A MINE

78. TRANSVERSE SECTION AT OGLE'S SHAFT

knocking up the projecting spindle. This is done when the bucket is at the surface and over a waggon or channel into which the water is discharged.

**A Pneumatic Water-tank.** In other forms the valve in some cases is opened automatically. But to save the time and cost of bailing, Professor Galloway has designed a pneumatic water-tank that consists of a cylindrical barrel 4 ft. 2 in. in diameter and 8 ft. high, closed at the top, in which there is a door

bolted to the cover to give access to the interior when necessary. The bottom is 5 in. above the base of the cylinder, and has a central opening 18 in. in diameter for the valve seat. The valve consists of a block of cast iron capped with a sheet of leather, and has a circular plate of iron 16 in. in diameter bolted to it, which

79. TEMPORARY TIMBERING OF A SHAFT

falls into the central aperture, leaving the ring of leather to make contact with the seating. A spindle working in guides, to ensure vertical movement, is connected to the valve by means of a ball-and-socket joint, which enables it to accommodate itself to the seat in any position in which it may be turned. The barrel is fitted with a gauge to show the height of the water, and with a pipe reaching to within an inch of the top of the barrel inside, provided with a cap for instantaneous coupling, as supplied by the Vacuum Brake Company. The barrel is sent to the bottom, plunged into the water it is desired to remove, and by means of pipes carried down the pit and 30 ft. or so of flexible hose is connected with air-pumps at the surface. By opening a stop-cock the interior is exhausted, the valve is lifted off its seat by the pressure of the atmospheric air on the surface of the water, and the latter rushes in, and in half a minute the barrel is full. The stop-cock is turned off, the instantaneous coupling is disconnected, and the barrel full of water wound to the surface.

**Air and Light.** Provision must also be made for a good supply of air to the sinkers, and this is done by a fan, and may be either by suction or blowing, the latter by preference. The fan should be sufficiently large to cope with the occurrence of gas, and to clear away the smoke rapidly after a round of shots. The air is conveyed down the shaft in sheet-iron pipes, 18 in. to 24 in. in diameter, spiked on the side of the shaft.

Artificial light is also required, and electric glow lamps are used for the purpose, although safety lamps are sometimes called into requisition when much gas is encountered.

**Keeping the Shaft Vertical.** A very important point is keeping the shaft absolutely vertical, and to this end, plumb-lines and centring devices are in constant requisition.

The centre line is either a cord or, better, a copper wire. One end of the wire or cord is coiled on a small drum, situated near the top of the pit, whilst the other end is directed by pulleys to the exact centre of the shaft, which is usually a hole bored through a balk of timber placed across the shaft; but a better plan is to provide a hinged arm of the desired length, built firmly into the masonry. When the line has passed through the centre hole, or over the arm, a weight is attached, and is lowered into a bucket of water at the bottom, so that the line is steadied. For setting out the curbs exactly, a series of weighted cords are hung all round the circumference of the shaft, which are attached to the inside of the upper curb, but every third curb should be checked by the main centre line.

Continued from  
page 3112

Fish. Fowl and Game. Eggs. Milk. Butter. Cheese. Bread. Flour  
and Grain Foods. Condiments and Tinned Foods. Cooking. Beverages

By Dr. A. T. SCHOFIELD

**Fish.** Fish is three-quarters water and one-quarter proteid. It is most easy of digestion when fresh, and is a valuable food, as it contains a large proportion of phosphates (ingredients of brain and bone). Tough, dry, and woolly fish are indigestible. Fat fish include salmon, herring, mackerel, eels, and sprats. Fresh fish are firm, the tail does not drop, the eye is bright, the gills are red, the smell is fresh, and the scales are bright.

Shell fish are not so digestible, except oysters, whose value as food is, however, much overrated. They are only in season in those months that contain the letter "R." Fish are preserved by drying, pickling, salting, smoking; parts of rich fish, however, are often decomposed.

**Fowl and Game.** The flesh is like meat in nutrition, but drier, and there are more phosphates. Goose, duck, and teal are hard to digest; rabbits are more digestible, but less nutritious than hares.

It is well to note here that, with rare exceptions, all flesh eaten by man is that of vegetable and not animal feeders.

**Eggs.** These contain all the food needed for the construction of the body, provided the shells are eaten. The proteids are in the white and yolk. The fat appears as oil in the yolk, and the starch as saccharine matter. If an egg weighs 2 oz., 10 per cent. is shell, 60 per cent. is white, and 30 per cent. is yolk. In a solution of 2 oz. of salt to one pint of water, a good egg sinks, but a bad egg floats.

**Milk.** Milk, again, contains all the elements of food, and in their right proportions. It may be described as an emulsion of fat, with proteids, sugar, fat and salt in solution in water. Milk is nine-tenths water and one-tenth solids. A rough analysis of the one-tenth (compared with cocoa, which contains no water) is as follows:

|             | Human Milk. | Cow's Milk. | Cocoa. |
|-------------|-------------|-------------|--------|
| Proteids .. | 1 1/2       | 1 1/2       | 1 1/2  |
| Sugar ..    | 1 1/2       | 1 1/2       | 1 1/2  |
| Fats ..     | 1 1/2       | 1 1/2       | 1 1/2  |

Nine pints of milk, equal to 23 oz. of food, is a diet for a man for a day.

In order of nutrition, cow's milk comes first, then human, goat's, ass's, and mare's. Ass's milk is nearest in composition to human. The cream in milk averages 10 per cent. If the milk is skimmed, 1 per cent. of the cream is still left; if separated, it is all removed.

Milk is a fluid very readily contaminated, and one in which germs flourish; it also readily absorbs poisonous gases. Milk should either be

got from a thoroughly protected and inspected dairy, or it should be boiled. Of course, both courses are safest.

Milk is least used in certain districts in the East End of London, where as little as 2 oz. per head per week is consumed. It is most used in Scotland and Ireland, where as much as 6 1/2 pints per head per week is consumed.

Forty per cent. of cream is butter, the rest is butter milk.

**Butter.** Butter is 14 parts water, 83 parts fat, and the rest sugar. It is remarkable as being the only one of the animal foods containing no proteids or nitrogen.

It is distinguished from margarine, a compound made from various animal fats to supply a substitute at a cheap rate, in three ways:

1. The specific gravity of butter is .05° higher than that of margarine.

2. The melting point of butter is 95° F. Animal fats raise it and vegetable fats lower it.

3. Butter has 8 per cent. soluble fats, margarine has 2 per cent. Margarine is as nutritious as butter, but less easily digested, on account of the difference of the fat as regards solubility.

The water in butter should not exceed 16 per cent.; in blended butters (butter and milk) it always does so.

**Cheese.** Cheese is the richest of all animal foods. It contains one-third only as much water as meat, but nearly three times as much proteid or nitrogenous food, and, in the richer cheeses, four times as much fat. It is therefore very much more nutritious than any meat, but much less digestible. It is important to distinguish between the two qualities, for the nutrition in anything is not of much use unless the food can be digested and assimilated. Some people of weak digestions find it almost as impossible to get their nitrogen from cheese as from air, though there is plenty in both. Cheese, such as Stilton, is made from *cream*, Cheddar from *milk*, Dutch and Somerset from *skim milk*.

Cheese which is ripe or slightly decomposed, such as Gorgonzola, is easier of digestion than fresh strong cheese like double Gloucester. If cheese be toasted, it is more indigestible; if grated, less so. One pound of cheese has more nourishment than three pounds of beef.

## Vegetable Foods

**Bread.** Bread is well named the "staff of life," though by many doctors it is now called the "bane of life," and the chief source of dyspepsia. The first title is more appropriate than the others.

Wheat contains (like milk) all the food necessary for life, and the needed salts.

## HEALTH

The germ of wheat has the same analysis as the solids (one-tenth) of cow's milk—*viz.*, one-third proteid, one-third starch, and one-third fat.

The analysis of various breads and of milk is as follows :

|                           | Proteids. | Starches. | Fats. |
|---------------------------|-----------|-----------|-------|
| White Bread               | 16.0      | 81        | 2.6   |
| Whole Meal                | 16.0      | 80        | 3.0   |
| Hovis Bread               | 20.0      | 58        | 19.4  |
| Human Milk<br>(Solids) .. | 24.0      | 50        | 24.0  |

This analysis shows that Hovis bread is by far the nearest to human milk. The reason other breads are so poor in fats is that ever since the grinding of flour by steel rollers, the fatty part of the grain is taken out, so as not to clog the rollers. In Hovis bread it is restored to the flour. Of course that is why ordinary bread is seldom eaten without fat—generally butter—being added to it.

Brown bread has by no means the superiority over white that is popularly supposed. It has a larger proportion of proteids in the loaf, but a smaller portion is kept in the body, 7 per cent. of it passing undigested. It is also irritating in its action if it contains the outer husk of the wheat.

Whole meal, ground fine, makes the most nourishing bread.

**How Bread is Made.** Bread is made as follows: The flour and water make a sticky mass (*dough*) owing to the gluten—the nitrogenous part. Some yeast ferment is added to the dough, which breaks up some of the starch into alcohol and carbonic acid gas, and thus aerates the mass, forming *sponge*. This is placed in a warm place, which increases the fermenting action; the alcohol evaporates and the carbonic acid is fixed in the cells of the bread; this is then baked to stop the fermentation.

The amount of water in bread is 50 per cent.

The most nutritious bread is made from *English flour*, but it is darker in colour than that from foreign flour. Only 90 loaves are made from a sack of English wheat, but 112 from a sack of Hungarian, which is therefore much more profitable to the bakers. Various methods are used for bleaching inferior flours, so as to give bread that white colour which is so much prized, but which has nothing to do with its value, the most recent process being by means of electrified air. [See BREADMAKING, page 3281.]

**Flour and Grain Foods.** The most nourishing foods made from flour are the Italian pastes—macaroni, vermicelli, etc. Those are nearly all gluten, and are nearly as nutritious as cheese. Macaroni, therefore, with cheese is the most nutritious dish known. The proteids in barley are not gluten, hence true bread cannot be made from this grain. Rye, on the other hand, can be made into bread because it contains gluten. Oats resemble barley, and can be made only into *oat cake* or porridge. Rice is rich in starch, but poor in proteids. Maize, or Indian corn, is more indigestible than other grains,

owing to its hard husk. Arrowroot, sago, tapioca are all rich in starch, but poor in nitrogenous food.

Peas and beans, on the contrary, are a most important food, as they contain a large amount of nitrogenous or proteid food in the form of legumin, or vegetable cheese. (Pea cheese is a known product.) As they also contain starch, fat and salts, they form in a sense a complete diet, unequal, though, to bread or milk. Potatoes are mostly water and starch; steamed in their skins they are more nutritious than when peeled and boiled.

**Vegetables and Fruit.** Vegetables are like milk in consisting of nine-tenths water; their value as food is due to the potash and other salts they contain, and to an antiscorbutic principle which they share with potatoes and lemons. In the last this power is due to citric acid. One ounce of lemon juice per head per day on shipboard prevents scurvy.

Fruits are also largely antiscorbutic, and contain valuable vegetable acids; the stones are dangerous, and the skins indigestible.

**Condiments.** These are of value in causing an increased flow of digestive juices.

Condiments are used to flavour salt dishes and meat, spices to flavour sweet dishes; both in *moderation* increase their digestibility.

Condiments include mustard, horseradish, pepper, curry, capsicum, parsley, mint, thyme, sage, vinegar, pickles, sauces, salt.

Spices include ginger, cinnamon, mace, nutmeg, cloves, allspice, caraway, vanilla, etc.

**Artificial and Tinned Foods.** Artificial and tinned foods are never quite equal in digestibility or nutrition to natural foods, and many are not only dangerous, but are made of such diseased and dirty materials, highly seasoned, as to be repulsive; they are best avoided.

Humanised milk is not equal to mother's milk. Condensed milk and milk powders are not equal to fresh milk. But this is all that can be said; for many are most pure, excellent, and nutritious preparations, identical in chemical constituents with the natural article, and forming, in time of need, most excellent substitutes for it.

Babies' foods of all sorts, and adult artificial and partly-cooked foods of every variety, under special names, are mostly wholesome, highly nutritious, and easily digested, and are very valuable on certain occasions. Their number is increasing, but they are often used needlessly when fresh food can be taken. We therefore repeat once more that fresh food is best when it can be obtained.

The same remark applies to tinned goods—meat, fish, and fruit. But with regard to these, which are so highly popular, there is another point. However carefully they are canned and the air excluded, here and there ptomaine poisons are formed and bad results ensue. The best safeguard is to turn the food right out of the tin as soon as it is opened. Tinned foods are used because they are cheaper, and often more easy to obtain than the fresh article; but they are not so good or so safe, and in the face of recent revelations most people will not use them.

## COOKING

Cooking is really a sort of first aid to digestion, in spite of the common idea that raw food is more digestible than cooked. Cooked food is better to the eye and taste; it is warm, more digestible, cleaner, more varied; you get many dishes from the same material, and parasites are destroyed; but against this the meat loses 20 to 30 per cent. of its water.

There are few things of more importance for the comfort and economy of the working classes than a sound knowledge of cooking. For want of it more food is wasted than would support thousands of starving people. A palatable meal would keep many a man from the public-house, and many sickly school-boys and girls would be made strong if they were only provided with wholesome, nutritious food, which, though plain, would supply the nourishment they now lack through ignorance and bad management. Much attention is being paid to this subject in primary schools, and it is hoped that it will soon be impossible for a man to marry a wife wholly ignorant of cooking, though it will be long enough before the English workman is as fortunate as the French peasant in this respect.

**Value of Good Cooking.** It is all very well for a strong man to say he cares little what he eats. It really makes an immense difference to him whether his food is well cooked or not, while to the weaker members of his family bad cooking often means ill-health. And if good cookery can be combined with economy, as it can, how important such knowledge is to the community.

For details on this important subject we must refer to the section on HOUSEKEEPING [page 1485] and to the practical instruction given at schools, polytechnics, young women's institutes and elsewhere. All we can do here is to lay down the following broad principles that distinguish good cookery from bad.

The object of all cooking is to make food more palatable and digestible, and to give variety. To this end it must be broken up and easily disintegrated. Skilful cooking does this, while bad cooking renders it hard, and difficult of digestion. A good cook, for instance, beats and bruises a steak before cooking it.

Cooking, also, by coagulating the fibrous tissue which holds the tissues together, renders them easy of separation. Meat is generally overdone, and vegetables are underdone. It would be better the other way about, for while underdone meat is not injurious, underdone farinaceous food is so, and provides a fertile source of dyspepsia.

Gas is as good for cooking as coal, if the oven be well ventilated.

Artificially and experimentally, food is digested as well raw as cooked, but practically in the living being it is better if cooked. Cooked food is more tasty and requires less mastication. In meat the tough fibrous tissue becomes a jelly, and in farinaceous food the tough covering of the starch grains swells and bursts, making the food readily digestible.

**Methods of Cooking.** There are seven principal forms of cooking—boiling, stewing, roasting, broiling, baking, frying and steaming.

**BOILING.** In many kitchens boiling means spoiling, for quick and fierce boiling soon hardens meat. The best way is to boil at  $212^{\circ}$  for a *very short time*, and then simmer at  $180^{\circ}$  the rest.

In boiling, the flesh gets firmer, the gelatine dissolves partly into gravy, and it sets again when cold; hence, cold meat is firmer than hot.

There are two ways of boiling—either with a view to extract the juices of the meat or to retain them. To *extract* the juices, the meat is placed, whole or cut up, in cold water and heated. Above  $180^{\circ}$  it hardens. The heat at first extracts part of the nutriment, and makes broth, leaving the meat still good to eat. Carried further, it makes soup and leaves the meat worthless.

In boiled meat, even when reduced to rags, some of the proteids (the flesh) are so hard that the muscle fibre often passes through the body unchanged.

To *retain* the juices in the meat, it should be plunged in boiling water and boiled for five minutes, to coagulate the outside, and then it can slowly simmer at  $180^{\circ}$ . The great fault in boiling is retaining the heat at  $212^{\circ}$  too long, and not reducing it soon enough to  $180^{\circ}$ . Fish is made firm and loses less of its flavour by being boiled in hard water, in sea water, or in water to which salt has been added.

Boiling is more sure to destroy all germs than any other form of cooking.

Boiled bones yield gelatine for soup; potatoes boiled in their skins retain their potash, salt, and albumen; if peeled, they are best eaten in their juice, as in Irish stew.

Beef tea should never be boiled, but very slowly simmered in a closed vessel.

**STEWING.** Stewing is by far the most delicate way of rendering meat tender, juicy, and sapid. Meat that would otherwise be eaten and digested with difficulty can thus be made quite digestible. Many foods, animal and vegetable, can be combined in stewing, and things rendered tasteful that are otherwise flavourless. All the most nutritious properties of the least nutritious materials can thus be obtained. It is often the best way of using tinned preserved meats. In this form the heat is never raised above  $180^{\circ}$ , and less water is used than in boiling. The meat and broth can both always be used. It is best to employ a water bath, or a bain marie for stewing.

**BRAISING.** This is a most excellent variety of stewing. The meat is just covered with a strong liquor of vegetable and animal juices, previously prepared (often with wine) and flavoured. It is simmered in this at  $180^{\circ}$  from two to three hours in a closely covered vessel with a sunken lid, on the top of which coals are placed.

**ROASTING.** In this process one-quarter of an hour is allowed to each pound of meat. The heat, as in boiling, should be great at first to coagulate the outside and prevent the escape of

## HEALTH

the juices; it should then be reduced, while all the time the meat is well basted. Roasting can be done before an open fire with a jack, or, as is more common now, in a well ventilated oven. Meat loses 30 to 35 per cent. by roasting; it loses least—25 per cent.—by boiling.

**BROILING.** This is a very fierce form of roasting, done on a gridiron over or close before a clean fire. It takes a shorter time, and is, perhaps, the most digestible form of cooking. It is the best way of cooking steaks and chops, and is also more palatable than any other, the meat having the taste of the fire on it. Fish is also excellent done in this way, as in a broiled sole. It is much more digestible than frying.

**BAKING.** Baking is always done in an oven, which should be hottest at first and then have its temperature reduced; it must be well ventilated. The heat required varies with the food cooked. Bread, for instance, requires a different heat from pastry. Baking is not quite so digestible a form of cooking as roasting.

**FRYING.** When this is done to perfection, a deep pan is used containing oil boiling at 500° F. The meat or fish is dropped into it, and coagulates outside so instantaneously that the food is not the least greasy, the oil having no time to soak into it if the right heat is maintained. Fresh olive oil is the best to use; the next is good beef dripping, clarified; and then comes lard.

**STEAMING.** An excellent process for many vegetables, especially potatoes, steaming can be extended to meat, etc. Steamers are sold to stand on gas stoves, consisting of four or more vessels one above another, with hot water in the lower, the steam from which is made to cook the whole dinner—fish, flesh, fowl, and pudding—very well and cheaply.

English meat has a fine flavour, whereas French meat is flavourless, and has to be disguised with sauces which often render it harder to digest.

**Carving.** This is the next important matter, and may be called the second aid to digestion, after cooking. Few have any idea how important good carving is. It may, indeed, be said that food that is not carved is nearly always indigestible—as lobster, crab, and salmon eaten in flakes. The object of all carving is to open up all the fibres to the ready action of the digestive fluids. For this reason good carving is across the grain and never with it. Food that is often not cut with a knife, such as salmon, is always rendered more digestible by its being divided across the grain. If meat, etc., is at all tough, a fine cutting across the fibre will often save an attack of indigestion.

**Comparative Digestibility.** We give, in conclusion, a table of the comparative length of time taken to digest different sorts of food. It is arranged alphabetically.

This table is almost entirely based on physiological experiments conducted in Canada for many years on Alexis St. Martin. He was a Canadian trapper who was accidentally shot in the stomach when hunting deer. The wound would not close, so a sort of window was made in the abdominal wall, through which the digestion

of food could be noted. From this source was derived the most valuable information as to the effects of alcohol on the stomach. It is only, however, approximately correct.

TABLE OF DIGESTIBILITY

|                       | Hours. |                       | Hours. |
|-----------------------|--------|-----------------------|--------|
| Barley, boiled ..     | 2      | Milk, boiled ..       | 2      |
| Beans, boiled ..      | 2½     | Mutton, boiled ..     | 3      |
| Beef, roast ..        | 3      | Peas, boiled ..       | 2      |
| Bread, brown, baked   | 4      | Pheasant, roast ..    | 3      |
| Bread, white, baked   | 3      | Pork, roast ..        | 5      |
| Cabbage, boiled ..    | 2½     | Pork, salt ..         | 5      |
| Eggs, raw ..          | 2      | Potatoes, peeled, ..  |        |
| Eggs, soft ..         | 3      | boiled ..             | 3½     |
| Eggs, hard ..         | 5      | Potatoes, in skin, .. |        |
| Fish, salmon, boiled  | 1½     | roast ..              | 2½     |
| Fish, sole, boiled .. | 2      | Rice, boiled ..       | 1      |
| Fowl, boiled ..       | 3      | Sago, boiled ..       | 1½     |
| Fowl, roast ..        | 3½     | Tapioca ..            | 2      |
| Ham, boiled ..        | 3      | Turkey, roast ..      | 4      |
| Lamb, boiled ..       | 2½     | Tripe, boiled ..      | 1      |
| Macaroni, boiled ..   | 2½     | Veal, roast ..        | 4      |
| Meat, raw ..          | 2      | Venison, roast ..     | 1½     |
| Milk, raw ..          | 2½     |                       |        |

## BEVERAGES

We purpose to consider, first of all, alcohol as a beverage in its various forms and compounds. In its reference to disease it is fully treated in the section on Ill Health.

Then we shall consider tea, coffee, and cocoa, those remarkable beverages that have contributed in no small degree to our national progress. We shall next speak of mineral waters and temperance beverages, and conclude with a brief consideration of water and the means by which it is rendered fit for drink.

**Alcoholic Drinks.** **ALCOHOL.** This is a spirit distilled from sugar. One part of sugar ( $C_6H_{12}O_6$ ) is broken up by fermentation in distillation into two parts of carbonic acid gas 2 ( $CO_2$ ) and two parts of alcohol 2 ( $C_2H_5O$ ). This takes place alike in the making of bread and beer. In making bread the fermentation breaks up the starchy sugar of the "Sponge" into carbonic acid and alcohol, the latter evaporates in baking, and the former is imprisoned in the dough and makes it rise. The smell of alcohol when bread is baking is quite perceptible. On the other hand, in a beer vat, where the same fermentation goes on, the alcohol is retained in the beer, and the carbonic acid gas is given off in such quantities that the men at the vat are sometimes poisoned by the fumes. Pure alcohol is about twice as strong as spirits, four times as strong as wine, and ten times as strong as beer.

**RECTIFIED SPIRIT** is alcohol with 16 per cent. of water.

**PROOF SPIRIT** is half water and half alcohol. Spirit over proof fires gunpowder.

No spirit for sale may contain less than 25 per cent. of alcohol; gin contains 35 per cent., brandy often 50 per cent.

**BRANDY** should be distilled from wine, but very seldom is so, except in the best French brandies. It is generally artificially made from some raw spirit distilled from potatoes, corn, etc., and containing fusel oil and other inferior and deleterious products, to which are

added tartaric and acetic acids, burnt sugar, etc. for flavour and colour, tannin, and, of course, water.

**WHISKY** is supposed to be made from pure malted grain, and *should be* the finest spirit made from corn as distinct from grapes. It is, however, constantly adulterated with potato spirit with much fusel oil, and produces rapid and violent intoxication.

**RUM** is a spirit distilled from molasses and often flavoured with slices of pineapple.

The three chief sources of the best alcohol therefore are grapes, grain and sugar.

**GIN** is said to be the spirit most drunk and the most adulterated with water; it would therefore be the least injurious if the original spirit were pure. It is flavoured with oil of juniper and thus becomes a diuretic.

There are many other spirits and liqueurs distilled in various ways, and amongst them we may mention *absinthe* or spirits of wormwood, as being very potent and one of the most pernicious spirits known, a great destroyer of the nervous system.

**Consumption of Spirits.** Most spirits consumed in the United Kingdom are made here; out of 40,000,000 gallons produced in one year, 32,000,000 were made at home and 8,000,000 imported, the proportion being four to one. The amount consumed does not vary very much in the United Kingdom, averaging about one gallon per head; while in the North of France it is increasing rapidly, there being in the Department du Nord a drinking house to every 15 males! Nearer Paris there is one to every 22, which is still vastly in excess of anything known here.

**Wines.** Turning to wines, we may remark generally that they should consist of the pure fermented juice of the grape. The so-called natural wines are, perhaps, the most wholesome of all the alcoholic products, and the most suitable for general beverages. They are everywhere the staple drink in wine-producing countries. In England such wines are little used or known.

The fermentation of the grape is due to germs in the air, a very different process from that produced by the yeast in bread and beer.

**NATURAL WINES** average from 6 per cent. to 12 per cent. of alcohol, and cannot exceed 14 per cent., because at this point fermentation stops. When fortified with spirits, however, as they nearly always are for the English market, the percentage ranges from 12 per cent. to 22 per cent. of alcohol, the latter being almost as strong as weak spirits, besides containing various compound ethers. If the spirit added were always of the highest quality, less harm would be done by fortifying, but unfortunately it is not so.

In light wines of low alcoholic strength a further fermentation (acetous) changing them into vinegar is apt to set in, if the air be not excluded.

Grape juice itself contains from 10 per cent. to 30 per cent. of sugar. In very dry cham-

pagne there is none, in other wines from eight to 60 grains in the ounce. There are generally from two to six grains of tartaric acid per ounce.

The germs in the air change the sugar in the grape juice into alcohol and carbonic acid, and they feed on the albumen in the grape. If this is used up before all the sugar is changed, the wine remains sweet. If the sugar is used up before the albumen, it is *dry*. A natural sweet wine can be made dry by continuing to add albumen (such as white of egg) during fermentation, till the sugar is used up. Wine is always most largely drunk where it is produced. In the United Kingdom, Germany and the United States, the consumption of wine is insignificant. The total amount drunk in these three countries with over 150,000,000 inhabitants is insignificant and only forms one tenth part of what is drunk in France alone with only 30,000,000 inhabitants; in other words, France drinks 40 bottles of wine per head for every one drunk by England, Germany, and America. Champagne, so largely drunk at festive gatherings, still scarcely averages one seventh of a bottle (reputed quarts) per head in England, the average price of champagne being sixty shillings a dozen. Of all wines together the consumption in the United Kingdom is under two quarts per head per annum. In the United States it is under one quart, while of champagne in America one bottle does for twenty people for a year, the average price being about eight shillings.

**Beer.** Beer was formerly a beverage brewed entirely from malt and hops, but it is now legal to brew it from sugar or its equivalent, with an added bitter, which need not be hops. Malt beer is made as follows: The barley grain is soaked for 50 hours, and then spread on floors for 14 days, during which time a large part of the starch in the barley is changed into a sugar by a ferment contained in the germinating grain. The grain is then dried in a kiln. This malted grain is crushed by the brewer and put into water at a temperature of 160°, thus forming a "mash" of which the liquor is called "wort." The mixture is then boiled to stop the fermentation, and hops are added. It is then run into shallow vessels at 60°, and yeast is put in to produce the alcoholic fermentation, and in a week the malt sugar is changed into alcohol and carbonic acid gas. If all the sugar be not changed into alcohol, the beer will not keep, but changes (as in light French wines) into vinegar by acetous fermentation.

The alcohol in beer varies from 2 to 12 per cent., and the malt extract from 4 to 15 per cent. Salt is often added to induce thirst.

Light (lager) beers contain 4 to 6 per cent. alcohol, but do not keep well. Ginger beer is a fermented liquor containing still less alcohol (from 1 to 4 per cent.), being thus practically a temperance drink, and sold as such.

**CIDER** and **PERRY** are really wine made from apples and pears respectively.

*Continued*

# THE TURNERY & MACHINE SHOP

**Allowances for Tooling. Lining Out. The Work of the Machines. Alternative Methods. Methods of Fixing. Machine Capacities. Broad Rules. Exceptions**

By JOSEPH G. HORNER

WE group together the turnery and machine shop because this is more suitable to the concise method of treatment which must be adopted in this course than a separation of turning from the other machine operations would be. It also coincides with the growth of present-day machine shop ideals. At a period comparatively recent, the work of the turnery and machine shops was of a very cut-and-dried character. Certain kinds of jobs went to the same kinds of machines year after year, because such had been the custom of the place. It was a lazy, mind-deadening practice, and it still exists in too many firms to-day. In the better firms it has disappeared before broader views, better education, and stress of competition. Though these great departments in large modern works are not only distinct but are also very much subdivided, yet in the large range of operations the management must always bear in mind the fact that economy in results must be of primary consideration. No old-fashioned prejudices in favour of or against the tooling of specific jobs on certain machines must be allowed to interfere with this. Old ideas and conservative practices have been and are rapidly changing in regard to the management of the turnery and machine shop.

**Alternative Methods.** Many pieces of work may be alternatively turned or planed, turned or milled, turned or slotted, planed, shaped, slotted, or milled, or turned in a common lathe, or in a turret lathe, or in an automatic machine, or screwed in a common lathe, or in an automatic, or in a chasing lathe. Though the results would be identical in each, the cost might be halved, or doubled, or lessened, or increased in much larger ratios by the substitution of one machine for another. This is, therefore, really the only way in which the vast volume of work done in a modern machine shop can be regarded—that of economy of output. And it is the point of view which it is very difficult for the workman trained in the operation of one particular machine to take. Hence the necessity for broad-minded management in the conduct of a department which often includes some hundreds of machine tools, large and small. The design and construction of the machines themselves will be treated in a later course, so that here we simply outline the character of the work involved.

**Allowances for Tooling.** The work of these departments lies in producing true surfaces of all conceivable shapes on all kinds of castings and forgings in various metals and alloys, but chiefly in iron, the bronzes, steel, aluminium, and aluminium alloys. The quantity to be removed is previously allowed for, and

embodied in the casting or forging, and it is most essential that this should be sufficient to hold up everywhere, without being excessive in amount. Practice allows, as a very general rule, from  $\frac{1}{16}$  in. to  $\frac{1}{4}$  in. for tooling, but this is subject to many variations, not only absolutely, but relatively—absolutely, when smaller or larger amounts are necessary on a surface; relatively, when pieces of work are complicated, or subject to troublesome conditions. Thus, it is not unusual to allow  $\frac{1}{4}$  in.,  $\frac{3}{8}$  in., or  $\frac{1}{2}$  in. on some portions of large cylinder castings, where it is essential that the bore, the feet, and the valve seats shall all be tooled in very accurate relations to each other. Here the uncertainty is due to inaccuracy in fixing cores, in setting back loose drawbacks, and in unequal and retarded shrinkages in cooling. The more the number of parts in a mould are multiplied, and the larger the casting, the greater are these risks. In a forging made by hand methods, extra allowances are made also with increase in mass and in the number of complications of related parts. It is not unusual to allow from  $\frac{1}{4}$  in. to 1 in. or more in some parts of large forged cranks, crane pillars, and forked rods. Forgings stamped in dies require less allowance than those made at the anvil; castings moulded by machine less than those moulded by hand.

**Lining Out.** Many castings and forgings have to be lined out, or marked out, before they can be safely tooled. If this were not done, some portions would not hold up—that is, the allowance, while in excess in some parts, would be insufficient in others. The object in lining out a casting or forging is, first, to avoid risks of excess, or insufficiency for tooling; and, secondly, to serve as a guide to the men who have to tool it. Often, of course, the tooling goes through the hands of two or three men, as turner, planer, and drill; or a planer, milling hand, and drill, etc. In such cases the advantage of lining out is obvious, as lessening risks of mistakes.

When an intricate casting or forging is being lined off, the marking out is at first of a tentative character. Several centres, lines, and circles, may have to be marked lightly first, and the positions of some altered afterwards, before the whole of the relations can be correctly obtained, to ensure that all will hold up alike.

This work is done generally by a fitter or turner, who is relegated specially and regularly to the task. It is done on large cast iron tables, planed truly on face and edges, and, with the help of an equipment of straightedges, squares, compasses, and other mathematical instruments. The lines are always scribed or scratched with a sharp point on a whitened surface—never

#### LINING OUT AND MACHINING

242-244. Lining out engine cylinder 245 and 246. Templates for ditto 247. Operations in the ordinary horizontal lathe 248. Operations in the vertical lathe 249. Drilling 250. Boring 251. A reamer 252. Bossing 253. Arboring 254 and 255. Planing 256 and 257. Slotting

pencilled—and the course of the lines is further indicated by *centre pops* stamped with a centre punch. The object ensured by *popping* is a permanent record in case the scribed lines should become partly obliterated during the rough handling of the work in the shop.

**The Necessity for Lining Out.** The reason for this may be easily understood. If a portion of the work were tooled without any reference to other sections, then some of these would probably fail to hold up to their dimensions. Or it would sometimes happen that too much material would have to be removed from one locality, leaving the metal too thin, or scant, in a plated or webbed portion; and the more intricate an object, the greater is the risk of this. But if a casting or a forging be marked off before any cutting is attempted, then inequalities can be averaged, by a process of give and take. The necessity for this is found in the fact that neither castings nor forgings when hand made can be relied on as of sufficient approximation to accuracy to permit this lining out to be dispensed with. And, apart from this, there is the fact that it is more convenient and economical of time to mark out all the dimensions, and the relationships of faces, bores, and bosses, etc., square, parallel, and so on, once for all, than to be working in a tentative and piecemeal fashion.

**An Example.** To illustrate this work in its elements, we take, say, a plain common cylinder for a small engine, and go through the work of lining it out.

When such a cylinder comes from the foundry it is rough, lumpy, and larger by certain predetermined allowances than the casting when finished and ready to be fitted. The principal parts to be finished are the bore and the faces of the various flanges, to be followed by the ports and stud holes.

Looking at the casting [242–244], we see that the *bore*, or hole, has to be parallel with three faces—that of the foot, A; steam chest flange, B; and exhaust branch, C; and that the flanges DD for the covers have to be at right angles with the bore. And these faces and the bore have all to be to definite dimensions, in relation to each other, as given on the shop working drawing, by which the liner-off has to work. It is necessary to set the cylinder up firmly on the marking-off table, thereby causing the flanges to stand horizontally and vertically, respectively, so that the surface gauge and square can be requisitioned by which to scribe the lines in question. In the illustration [242] the cylinder is packed on wood blocking. An alternative is to use small iron wedges to pack up with, for it must be remembered that the face of the foot is only rough-cast, and therefore uneven. Some averaging has to be done. The back of each flange has to be checked, and brought parallel and square respectively, for if the flange faces were marked, ignoring the backs, there would be a difference in thickness on opposite edges when the faces were tooled. But as there is no true face as yet to commence from, the casting is packed up on the blocking as shown, and adjusted thereon, until not only the bore

centres measure the same height from the table at each end, but the backs of the flanges measure parallel and square respectively. The scribing block tests the first, or the rule in some cases, and the common square the second. The packing may consist of wedges, or thick blocks, or vee-blocks, the latter to receive the circular flanges.

**Marking Centres and Centre Lines.** It is usual to commence with the bore, bridging each end with a strip of wood or metal, *a*, driven in tightly [see also 244, which shows the exhaust bridged similarly], and marking a centre thereon with compass, or compass calliper, from the edge of the roughly cored hole, *b*. Then measurements are taken from these centres at each end of the cylinders, with the rule first, to the various flange faces. Now if, as often happens, some of these faces A, B, or C lie too close in, or stand too far out, the bore centres are shifted over to allow of all the flanges holding up. And it will thus often happen that shifting the centres will reduce the allowance for boring very fine on one side and increase it by perhaps double as much on the side opposite.

The bore of the finished hole may next be struck round, line *c*, with compasses at each end, from the working centres. Another line, *d*, is now struck concentrically, from  $\frac{1}{16}$  in. to  $\frac{1}{8}$  in. away from the bore line, as a *witness* to remain after the boring is done, testifying to the fact that the circle struck has been worked by. In the absence of the witness it would not be possible to prove or disprove this fact.

The next thing is to get two lines across the end flanges at right angles with each other, and both passing through the centres of the bore. These are seen marked on one end in 242, and from them the faces of the flanges A, B, C are measured and marked. The horizontal lines are drawn with the surface gauge E, the points of which are adjustable for height, the vertical ones with a common try square, or set square.

When the flanges B and C are set, then the dimension lines for the faces can be marked as shown, with scribing block and square. Witness lines are sometimes struck within these, sometimes not.

**Flanges and Ports.** The faces of the circular cover flanges, DD, are marked with a scriber with the cylinder set on end, the scriber being able to operate then from the face of the table. It is packed up on blocks or wedges, or both, being adjusted by the centre lines of the bore, carried round the edges of the flanges for that purpose. If there be slight inaccuracy here it will not matter, because the flanges are faced at the time of boring, and therefore must be at right angles with the bore. The lines simply give the length over all, the lathe or boring machine taking charge of the truth of the flange faces. After the valve face, *f*, and the face, *e*, for the steam chest have been planed, the ports are marked out. Their edges have to be filed, or milled, for a sharp cut-off of steam. They are marked by the centre lines on

that face. But a templet [245] is generally used for marking them all three at once. A templet [246] is also often used for marking out or drilling the stud holes directly through. These various holes are shown on the flange faces, all centre popped. The centre popping is necessary if the holes have to be drilled by the circles, but not when they are drilled directly through a templet.

**Setting and Tooling.** By the lines and pops thus marked, the machinists and turners have to tool the castings and forgings. As these are in a rough condition, offering as yet no true plane faces, or cylindrical surfaces, external or internal (bores) by which to set and fasten the work, the marked out lines alone must afford at first the means of setting by. This setting is a very important part of the duties of the turner and machinist. It may be stated at once that mere rule measurement is of little service, except for approximate preliminary adjustments. The pointed instruments used in lining out are also employed to check the lines by when setting in the machines—they are chiefly the scriber and compasses. Measurement is taken from a true face on lathe or machine to the lines scribed on the work. After one face has been tooled that is generally, if practicable, utilised as a means of resetting, when more than one setting is necessary. In some cases a rough cut is taken on a surface before commencing the lining out, or the tooling proper, simply to provide a basis for operations. This might be done on the foot A, in 242. In any case, the selection of the portion to be first tooled is not made at random, but with due consideration for the convenience or accuracy of subsequent operations.

**Checking Dimensions.** During the progress of the work in lathe or machine the scribed lines alone do not afford a sufficiently accurate guide for final finishing cuts. An actual line, unlike the mathematical line, has a very sensible thickness, and working to one margin or the other of it might easily make two or three thousandths of an inch difference, and one-thousandth is too coarse a limit for much machined work. Here, then, the calipers and gauges come in, where the sense of contact is much more exact and fine than that of the appreciation of a line. Generally in tooling, the lines are supposed to be just obliterated, and only the margins of centre pops are left. If a man cuts too deeply, and then smudges the surface over, or bores a hole eccentrically, it is impossible to charge him certainly with error, and blame may be thrown on the liner-out. Hence the reason why, in some cases, another line is struck outside the actual one, which becomes a witness line, remaining after the tooling has been done, as in 242, d.

There is a practice to be noted later which is always growing, to the displacement of the necessity for marking out. It is that of *templeting* and *jig making*. There is also the practice of the automatic machines, to which we return in the next article.

**Lathe Work.** If we now look about the shop in order to see how best to tool a

given piece of work we find that machines may be very roughly classified according to their methods of operation. Lathes, for instance, are designed for producing circular forms by the rotation of the work against the rigid cutting tool [247]. And they are equally adapted for producing external surfaces—*turning*, as at A, or internal—*boring* as at B. But if the tool, instead of being operated in the longitudinal axis of the lathe, be worked perpendicularly thereto, as at C, against a rotating piece, a plane surface will be produced, *facing*. So here is a machine tool that will produce in a perfectly legitimate manner plane and circular forms.

The general idea of a lathe is one the axis of which is horizontal. But there is a group that has grown rapidly of late years, the *vertical* lathe, in which the axis of revolution is vertical. The advantages of its use are very great in heavy work, and in light work, for operating on detached segmental pieces as well as on large cylindrical ones. An important function of these machines has given an alternative name to them, *boring mills*, or the *boring and turning mills*. So that here [248], as in the common horizontal lathes, we have the functions of boring (A) and turning (B) combined, in which also facing (C) is included.

**Work of the Drilling Machines.** It is not a far cry from the vertical boring mills to the vertical drilling and boring machines. And as we have horizontal and vertical lathes, so we have also horizontal and vertical drilling and boring machines. This is one illustration among others of the overlapping of machine tool types. Drilling and boring differ mainly in dimensions. A small hole is *drilled*, or any hole is initiated by drilling [249]. A hole of fair dimensions is *bored*, or is enlarged by boring [250], or by reamering [251]. Both have the rotary motion in common with the lathe, but in the drills and boring machines the tool rotates and the work is stationary. Yet the results achieved are identical. And the boring machines can be used for turning shallow bosses, *bossing* [252], and for facing, *ar boring* [253], by which their utilities are extended. It is clear, therefore, that since identical functions can be performed in either group of machines, the question of sending work to one or the other is not one of necessity, but of convenience; such as the dimensions of a piece, the relations of the different surfaces, or the question of one or more settings, etc.

**Reciprocating Machines.** In this great group of machines, of which the planers, shapers, slotters, and keyway cutters are the leading representatives, we have an immense variety in design and dimensions. The feature common to all is the linear, and to-and-fro movements of either the work or the tool. Often it is one, often it is the other, that is reciprocated. The results produced are plane surfaces in horizontal, vertical, or angular planes. But in the shapers and slotters there are other provisions by means of which the work is rotated in relation to the linearly-moving tool, so producing circles and circular arcs. So that here also some of the

work of the lathe may be appropriated, just as the lathe, when used in producing plane surfaces in facing operations, takes some of the work of the reciprocating tools.

All the machine tools in the groups already mentioned have one feature in common, the employment of cutting tools having narrow cutting edges. The obvious result is that a movement of *traverse* at right angles to the length of cut must be imparted either to the tool or to the work; it does not matter which, as far as results are concerned.

#### Milling and Grinding Machines.

But there are now two other large groups of machine tools, of very great and growing importance, which have little in common with the others that employ narrow, single-cutting edges—so far as design and method of operation are concerned; yet they produce similar results. These are the *milling* and *grinding* machines.

being cut with single-edged tools, cranked, as in 255. In the planer, the table carrying the work moves, as in 255; in the shaper the tool moves, and the work is stationary. Figs. 256 and 257 show the same piece of work laid on the table of a slotting machine, in which the tool A has a reciprocating movement in the vertical direction. Another tool with square edges would be inserted for cutting the inside shoulders that form the seating for the cap. Figs. 258 and 259 show how precisely the same results are obtained by the use of rotating milling cutters. The top faces are done equally well with an end mill like A, or an edge mill like B. The end mill is the more suitable for cutting down the shoulders, though the edge mill can be used if provided with teeth at the ends.

**Bossing.** Fig. 260 shows a bossed end rigged up on the cone mandrel of a shaping

MACHINING OPERATIONS

258 and 259. Milling 260. Shaping 261 and 262. Slotting 263. Milling

There is scarcely any operation done in lathe, drill, boring machine, planer, shaper, or slotter that is not also done legitimately on miller and grinder. Many of these machines are modelled so closely on the lines of the tools previously mentioned that they might well be mistaken for such at a casual glance. There are horizontal and vertical grinders, much like horizontal lathes, and vertical boring mills. Reciprocating grinders are built similarly to planing machines and shapers. Each is regularly doing similar work. Cylinder borers, as well as external cylinders, are milled, or ground; plane surfaces are also milled, and ground, besides other operations which we have yet to consider.

**Alternatives.** Figs. 254 to 263 illustrate a few alternatives; 254 and 255 show a plummer block on the table of a planer or shaper, and

machine, a rotary feed being imparted to the arbor—made conically to centre the work by its bore—as indicated by the dotted outline. After each cut, a portion of a turn is given. The tool reciprocates simply, but the result is a circular boss produced as truly as though done in the lathe, but with the advantage that the movement can be arrested at the precise location where the round boss merges into the straight bar. But, of course, a complete circular boss may be produced in the shaping machine if such were necessary. Figs. 261 and 262 illustrate the same work mounted on a slotting machine. But in this case a rotary movement is imparted to the machine table, the centre of which coincides with the axis of the boss being toolled. Both in shaper and slotter the straight portion of the bar may be toolled at the same setting by throwing

out the circular feed and substituting the longitudinal. In this respect the shapers and slotters have a wider utility than the planing machine, in which no provision exists for combinations of straight with circular tooling.

Still taking the same example, the circular-ended lever [263] shows how the same results are obtained with a milling cutter operated in a vertical spindle machine. The same circular and lineal movements are imparted to the work through the medium of the table slides, and an edge mill—like B in 259, but with its axis set vertically—indicated in 263 in various positions, produces the required outline. It is possible also to obtain similar results by grinding wheels; but this, and the further consideration of milling operations, will be found in the next article. In the meantime, there are other matters suggested or illustrated by these drawings to which reference must be made here.

**Horizontal and Vertical Arrangements.** The difference between the horizontal arrangement in 247 and the vertical in 248 to 253 should be noted. Fig. 247 is the lathe design, and, but for the fact that lathes are used as much or more for turning long pieces supported between centres as for short pieces, there is little doubt that most *face work*, as that in 247 is termed, would be relegated to the vertical machine [248]. The full advantages of the latter are not apparent in the example shown; yet it is clear that the horizontal table F affords better facilities for setting and centring work upon than does the vertical face plate, or chuck, E, in 247. In this the piece has to be held or slung while setting; in 248 it is simply laid on the plate. And if, instead of a single piece, a number of segmental objects had to be arranged requiring arcs of a circle to be turned on each, then the awkwardness of setting them in 247 is obvious. More than this, the borings fall away at once downwards in 248 through the hole in the table, while in 247 they lie in the bottom of the bore, and have to be cleared out from time to time. Very often work is bored only in 248, and subsequently rechucked in 247 for turning; this is frequently done with pulleys and other large objects.

In the drilling machines the vertical spindle arrangement predominates vastly over the horizontal. The latter are practically confined to special machines for pipes and similar work, where the length is too great to be handled conveniently in a vertical position.

**Horizontal and Vertical Cutting.** In the reciprocating group of tools the horizontal traverse of the cut is mostly adopted [255 and 260]. There are several reasons for this, but the principal one is that it would be practically impossible to tool vertical faces of considerable length unless the entire tool carriage were travelled bodily on a continuous guide—unlike the shaper and slotter rams, which overhang. This is done in the vertical planers, but they are built for special rather than general utilities. Hence the use of the slotting tool [257 and 262] is generally restricted, like that of the shaper, to maximum strokes

of from 16 to 24 in., while the planer tools [255], being fixed and supported in a rigid tool-box, with constant overhang, operate over lengths of 30 or 40 ft., or more in special cases.

**Movement of Tool or Work.** Another point which invites attention is the alternative of moving the tool, or the work. It seems unmechanical to travel a massive machine table, often weighing some tons, with its work, under a tool [255] which, with its carriage and cross-rail, may weigh less than a ton. Experiments have proved that by far the largest amount of power taken by planing machines is absorbed by the movements of the table, and scarcely anything in the actual cutting. Yet the convenience and stability of the arrangement ensure its retention. For some exceptionally massive work, machines are built in which the tool with its cross-slide and housings travel over a stationary bed. The side planers, in which the tool is traversed over fixed work, are largely employed, but they have limitations in respect of overhang of the tool-arm, as in shapers, but in a less pronounced degree. Small portable planers fill a useful place; but, with these exceptions, the moving work and the fixed tool is the rule in by far the largest number of planing machines in use.

The distinctive characteristics of the tools shown here and in subsequent articles will be treated in the course on Tools, but their rigidity, and the differences in the forms of their cutting edges, may be noted here.

**Choice of Machines.** The question now naturally arises: why substitute the work of one group of machines for that of another, if the results are alike? The work of a milling cutter or a grinding wheel, for example, for that of a single-edged tool? These questions will be answered at length in Tools and Machine Tools. It is sufficient here to point out that the advantages in some cases are unquestionable and great, in others the balance is nearly even; and that these questions can be considered and answered fully only in relation to the special and individual piece of work in hand, the particular machines available in a shop for doing it, and, as important as either, the system of manufacture carried on in a given shop, whether the *fittings* or *assembling*, the *general* or the *interchangeable*, of which more later. In speaking of a type of machine, it must always be remembered that the type generally includes some scores of sub-types and sizes. The lathe does, the planer does, so do the milling machine and the grinding machine. And although we have not yet mentioned them, so do the *gear cutters*, which are divisible into groups, using either reciprocating or rotary cutters. So that to call a machine a lathe, a planer, a grinder, a gear cutter, would convey but the baldest ideas, and would be of no real use to the operative in the shops, without naming the class and capacity of the machine in question.

**Multiplication of Tools.** Nor have we said anything yet of another very potent element in economical production—that of utilising several tools in one machine. The

single-tool machine is just a step in advance of the single tool once held in the hand of the craftsman, and then put into a machine and backed up by the power of an engine. Whitworth made a daring innovation when he substituted two tools for one in the lathe. Now many lathes have four, some six, a few as many as eight, cutting simultaneously. But the lathe does not lend itself so readily to simultaneous cutting as do some other machines. Drilling machines will make from half a dozen to forty holes or more simultaneously, so will some punching machines. Many planing and slotting machines take two cuts or more at once, and many planers cut on both strokes. But the principle of multiple tools is seen in its highest development in the turret lathes and automatic screw machines, where, though two tools sometimes operate simultaneously, the principal feature is the *successive* operation of several tools on a single piece of work. The turret lathe owes its value to the fact that all the tools required for a cycle of operation on one piece, or often on two or more pieces, are fixed, and set once for all in the turret, and cross slide. When once set they will operate on hundreds of similar pieces without stopping for check or measurement, and until the tools require to be reground or sharpened. The correct dimensions of the work are embodied in the tools, and in their fixing up in the turret, and cross slide; and stops take charge of the termination of each single operation in the cycle, and at the right instant. In the most highly developed turret lathes—the *automatics*—no attendance is necessary beyond that of supplying the machines with stock.

Enough has been said to show that the work of the machine shops and turnery, in which the parts of mechanisms are cut and ground to precise shapes and dimensions, is a subject which may well exercise the highest talents of the skilled mechanic in charge. While there are some kinds of work which may be done in several different ways, in others the conditions are such that no doubt exists as to the best machine on which to do them.

**Fixing Work.** We now go a stage further, and find that the actual work of cutting is not the only thing which has to be considered in the shops. Everything, whether casting or forging, heavy or light, has to be fixed firmly in some way, in order to enable it to endure the stress of cutting without becoming shifted from its place. This question alone in some cases determines upon what machine a given piece of work shall be put, and that again must depend frequently, not on what is the best machine for the purpose, but the best which happens to be available. Out of this arises the problem of *makeshifts*, common enough to all shops hampered with badly-selected machines—*makeshifts* which often exercise the ingenuity of the men in charge much more than the regular fixings do.

The work of fixing is facilitated by the plain slots, or the grooves of tee section, which are formed in all the ordinary tables of machine

tools, and the face plates of lathes. The slots, or grooves of tee section, receive bolts having heads of corresponding shape, by which the work is secured. The bolts may be tightened on the faces of the work or on broad washer plates placed on the work, or in some form or other of special clamping plates, which are very varied, to suit different jobs. Very often a piece of work is of a shape that will not permit it to be bolted directly to a face plate or to a machine table. It is then generally held by an *angle plate*. This is an intermediate fixture having two faces at right angles, against one of which the piece of work is bolted, and the other face is bolted to the plate or table.

Again, there are many jobs which cannot be clamped directly in opposition either to table or angle plate, but which have to be held by lateral pressure, or clamping screws, or dogs, leaving faces absolutely clear of clamping arrangements. Outside of these, again, is a large volume of work for which special fixtures, more or less elaborate, are designed for holding a certain kind of work only.

In holding work, though security is absolutely necessary, there is an evil to be guarded against which is very common—that of exercising too great pressure without affording adequate opposing support. All metal is sensibly elastic, and if fastened down in too rigid a manner it will become bent, and, springing back when released, the surface tooled will not then be true.

**Packings.** It is, therefore, always essential when clamping down is being done to be sure that the work is supported in opposition to the clamping bolts. This is the reason why packings are inserted where the work does not touch the table, and why bolts are inserted close to packings, or to metal in contact with the table. Through neglect of these precautions castings have been broken, and castings and forgings bent and spoiled.

**Examples of Fixings.** The turner is well provided with means for holding work in the various chucks which are fitted to the mandrel nose, and which will be illustrated in the description of the Lathe. In 247 the piece of work is being held in the common jaws, D, of the four-jaw chuck, which may be independent, or self-centring. Similar chucks are used on vertical lathes, but 248 shows clamping plates D, which are pulled down tightly by bolts, both on the flange of the piece of work and on the packings, E, which are either of metal, as shown, or of timber. The object of packing up is to support the clamping plates level with the top of the face being held down. The bolts, which secure the clamps usually have square or tee-shaped heads to fit in tee grooves on the machine tables, because ordinary bolts cannot usually be pushed up through the tables. Two such bolts are shown in 249 in their grooves; and others occur in 254, 258, and 262; the method of clamping is similar to that in 248. But it will be noted that the packing pieces in 249 are very deep, owing to the necessity of packing up the piece of work on a ring, A, to

264. TURNERY (Messrs. Willans & Robinson, Ltd., Rugby)

permit the drill to pass through without fouling the table. The same device occurs in 250, but here the clamping pieces are cranked; this method is often adopted to keep the nuts low down when they might be in the way of tools, as in 252. In 258 and 259 the clamping plates are bent in order to avoid the necessity of using packings at all, but these have to be stocked in various depths to accommodate differing thicknesses of work. In 256 and 257 U-clamps are employed, made by bending a piece of flat bar. The advantage is that they can be slid along, instead of being confined to one position by the drilling of a bolt hole. In 257 and 262 the work is packed up to permit the slotting tool to go past it, completing the cut, just as packings were inserted under 249 and 250 to permit the drill and boring tool respectively to clear through. The clamp in 261 and 262 (A) is a plain plate, with bolts passing down each side of the work, packings being therefore unnecessary. Packing is only used if the plate be very thin. The plate at B in the same figure is in the form of a disc, through which a single bolt passes.

**The Question of Refixing.** Closely related to the methods of fastening work is that of tooling the different parts of a single piece without refixing, or with the minimum of refixing. Related to this again is the question of performing all operations on one machine, or of dividing them between machines of different

kinds. These problems, which present many alternatives, loom large in any shop system where due regard is had to economies. We have seen that similar results can be obtained on different kinds of machines, and of this fact full advantage is taken in modern works by changing work as little as possible from one machine to another; which changing is, of course, expensive, because it occupies time, and often the use of lifting and conveying tackle. This is especially so in massive work; hence the tendency has long been to design machines to carry through several operations on heavy pieces without refixing them. Thus, for example, this provision is combined in a single machine for drilling, boring, and screwing; or for planing, milling, and drilling.

In a much larger number of cases the provision made is for the simultaneous operation of several cutting tools operating on different portions of a piece of work, by which the necessity for refixing it is avoided, as in the turret lathe just instanced. Thus, a planing or a milling machine will often be cutting on three faces at once—the top and two sides. In a few cases ends, as well as sides, can be planed without shifting the work. Drilling machines are made capable of drilling many holes simultaneously, and sometimes in different planes—as vertical and horizontal. Boring machines are made for boring two cylinders combined in one casting

at once; gear-cutting machines for cutting more than one tooth at once. In each case the object attained is twofold—to avoid or lessen the number of resettings, and to increase the number of tools cutting at one time.

**Accuracy of Related Parts.** A closer approach to accurate results is generally obtainable when work is not refixed than when its position is changed on the same or on different machines. To take a familiar example: An engine cylinder [242] is bored, and its flanges, DD, faced at the same fixing. This ensures the faced ends standing at exact right angles with the axis and bore of the cylinder, because the revolution of the boring bar around its axis is made the means both for boring and facing. Often also the outer edges of the flanges are turned by the same agent, and at the same setting, so ensuring their concentricity with the bore. The feet, A, and valve port faces, B, and exhaust flange, C, have to be done on a separate machine—the planer, or milling machine. In these cases, though there is the lining out to work by, the casting is always set and checked on the machine table by the portion already tooled—namely, by the bore, and ends of the flanges. And whenever a piece of work has to be removed from one machine to another, precautions of this kind are taken. Thus, many wheels are bored on one machine and turned on another. Then, the boring being done first, the wheel is chucked by that on a mandrel, and the bore being run truly, the turning is bound to be concentric with it.

**Machine Capacities.** A matter of which constant note has to be taken is that of the capacities of machines. Generally, a piece of work is put on a machine of dimensions most suitable to receive it. Thus, long pieces with plane faces go on the planer, or plano-milling machine, short ones on the shaper, or on the slotter. The reason is that the first-named are long-stroke machines, but the latter are always short; and it does not pay to do short pieces on machines made for long strokes, because their proper capacity is not then utilised. But if a sufficient number of similar short pieces have to be tooled, then it is often cheaper to put them on a long-stroke machine, arranged in series, and to tool the lot. Thus, several cylinders [242] or plummer blocks [254, 255, 258, and 259] might be so treated. Further, the choice of a machine is often controlled by the shape as well as the dimensions of the work. Thus, a machine vice is frequently essential, in others an angle plate is preferable to the fastening down with clamping bolts. Lathe work is taken to the lathe, the swing of which approaches most nearly to the diameter of the work, or the length of which is suitable between centres. Big pieces go on big machines, and small articles on small machines. This is a matter for economy as well

as of convenience, because the capital cost of large machines and the charges for their use are high, and it would not do to saddle small work with those charges.

**Exceptions to Broad Rules.** But the machine shop manager must not be bound too tightly by these general rules. For the volume of work of a given kind fluctuates in all shops at certain times, so that it is not always possible for him to do just what he would like. Big machines standing idle for seasons cause serious loss of income. In such cases, then, it is better to occupy them with some kind of work, even though that which is not, on the whole, the best suited to their capacity, than to lose money. But it is generally possible by the exercise of some foresight to take a middle course. A planing machine, or a plano-miller of large capacity, though properly adaptable to long pieces of work, can be employed as economically on a number of small pieces arranged in series, provided there be a sufficient number of pieces all alike. This is often done as alternative to putting the pieces singly on the short-stroke shaper, or slotter, and tooling each piece separately in these machines. Much work can alternatively be put on vertical lathes, preferably to horizontal. Division of work between two machines may be practised simply to lighten the tasks of some of those which are glutted with work. The point is, that if the best possible economics are not always obtainable, the best under the circumstances are made.

**Work of Unusual Shapes.** Often the very awkward character of a piece of work settles the type of machine on which it is to be put. Thus, some castings and forgings lie beyond the capacity of an ordinary planing machine, being too wide to go between the housings, or too high to go under the cross rail. Then it is usual to rig up a makeshift supplementary tool-post to plane the vertical faces in front of the housings. Supposing no other machines are available in the shop, this is the only device suitable. But a better method is to use either the wall planer or the side planer for such work, because neither of these have any obstructions to the dimensions of the work that can be placed in front of them. There are a good many jobs of this kind, especially in marine engine works—pieces so massive that they occupy so large an area that no machine would enclose them. The open-side machines are designed for such articles. But there is a growing rivalry to these in the small portable machines which are taken to, and set down upon, or next the work, and driven through an electric cable. It is obvious, therefore, that the makeshift methods inevitable in some machine shops are not necessary in those which are fully equipped with all kinds of modern tools, and that no proper critical comparison could be made between the methods of the two.

The Value of Metal Work in Vehicles. Various Types of Axles and their Details. Tools. Vehicle Fittings

VEHICLE CONSTRUCTION  
continued from  
page 3129

By H. J. BUTLER

**A**LTHOUGH we have seen that the vehicle is essentially a wooden structure, yet there is much metal work—notably iron and steel—in the completed body and under-carriage. In axles and their attachment to the body we see how necessary it is that this branch of the work should be properly carried out, for the failure of these parts has often been the result of serious loss of life.

In broughams and landaus is to be found a vital piece of metal work—the edgeplate. The body in itself, cut nearly in two at the doorway, requires to be specially strengthened by a piece of ironwork, which is fixed edgewise inside along the main framing of the body. If one glances at a square landau body and imagines the doors taken away—for, being hinged, they are not an integral part of the body structure—a cranked-shaped body is seen with a seat on each side helping to enlarge the opening independent of the strains of the driving boot and fore-carriage, and the weight of an open folding head.

Motor-cars and railway rolling stock do not require this edgeplate, as they are already supported on a properly strengthened frame, be it pressed steel or wood flitched with iron plates.

**Importance of Metal in Vehicles.** In under-carriages both for road and rail there are many instances where the proper disposal of iron or steel is of paramount importance.

The king bolt, centre pin, or perch bolt, the plates of the bolster, transom, and axle-beds, the springs, whatever their type and fastenings, the metal perch of a perch carriage, are instances where we expect to see the design and workmanship carried out with safety as a first consideration. Apart from this, there is the brake-work, which in all vehicles is essentially an apparatus of metal.

Then metal-working finds an outlet in the many interior and exterior fittings that make a convenient and useful conveyance. Such things are step treads and their fixings, handles, locks, and hinges, heating, lighting, and ventilating apparatus, sanitary fittings, and many other miscellaneous items, such as hat-pegs and racks, and attachments for the convenience of smokers.

**The Motor Body Metal Shop.** The coachbuilder of to-day has a metal-work shop besides the smith's shop. The motor branch of the trade is too young for anyone to have been apprenticed to it, the workmen being drawn from the metal-working trades that already exist. In this shop the panels of tonneaus and phaetons are shaped by rolling and hand hammering, and such panels of a curved character in limousines and other bodies that do not lend themselves to be constructed

of mahogany. The brass edging and guards of the long side steps, the metal wings, sprocket covers, and number-plates are the particular items that are entrusted to this part of the motor body builder's shop. Aluminium channel is sometimes used for the framework of a body in place of English ash, often the only wood-work being the framed seat boards. Necessarily we must insert wooden trimming rails for the proper fastening of the squabbing.

**Metal Mouldings.** Not only are the panels of aluminium, but the moulding, generally half round in section, is of the same material. Small bolts and screws are the medium for fixing these mouldings, and unless a panel can be finished off with a moulding into which screw and bolt heads can be countersunk, it is wiser to resort to wood. A wooden panel can be pinned on; but not so a metal one, which must be screwed, otherwise we should have the screw heads showing after the job is painted.

**Sprocket Covers.** The chain-driven car requires, in the side entry type, a suitable protection over the greasy sprocket wheel. A well-made cover is designed to harmonise with the body outline and provided with an inspection door with a proper handle working with a spring, and the whole is securely fastened to the hind wing and long side step.

**Metal Wings.** Mudguards of rolled steel with moulded edges are very much used on motor-cars, and are better than bent wood, as they do not split, and, when properly stove-enamelled, as they should be (not coach-painted), they look almost as well, and have none of the disadvantages of a patent leather wing stitched to a wrought-iron frame.

**Lamp Repairs.** The metal-plate worker is generally quite capable of repairing any of the numerous types of motor dash and head lamps, and his usefulness can be extended to the repairing of leaky petrol tanks, altering engine bonnets and the construction of neat number-plates, lengthening trumpets for speaking tubes, and many other little jobs beyond the province of the coachsmith.

**Axles.** In most animal-drawn road vehicles the axle is stationary [50-54], but in railway work we find the axle or journal box fixed through the medium of the springs and other immediate fittings to the body, the axle arm and bed revolving.

In carriages and vans we find the springs connecting the body and axles direct, while the axle-box revolves with the wheel round the arm. The revolving railway axle is sometimes utilised to generate electricity for the lighting of the superimposed body.

**Axle Types and Materials.** Axles may be of wrought iron or steel, solid or hollow, and are of different patterns, such as straight, cranked, swept, and of varying sections, round and square being the most common.

We find railway car and tram wheels forced on by hydraulic power, while in road vehicles we find a retaining pin, nut, or series of nuts preventing the wheel from leaving the arm. Wrought-iron railway axles, according to the Master Car Builders' Association of America, must be of double-worked, fagoted scrap, 16 per cent. of new bar iron worked into the centre being allowed if desired. These axles must also be well hammered and free from open seams, holes, pieces shelled out, or similar flaws. Under the same code, steel axles have their composition defined, carbon being set down at 0.4 per cent. Both varieties are subjected to a physical test as to their strength in proportion to size, while steel axles are also subject to chemical analysis.

An axle made from a bloom consists in binding together by wires selected scrap (old bolts being well suited), bringing it to a welding heat, and then shaping it under a steam hammer.

50. SECTION OF A STOCK AND AXLE-BOX, REVEALING THE ARM OF A MAIL AXLE

After hammering, the mass is drawn out into a band, reheated, and forged into shape with swells that may be worked up into the collar and flap. A fagoted axle consists of a number of small bars, welded together longitudinally.

**Sizes of Axles.** An axle journal supporting a 50-ton freight car—an American ton is equal to 20 cwt. of 100 lb. each—is 5½ in. in diameter by 10 in. long, but it must not be forgotten that the weight, being mounted on trucks, is distributed over four axles. An English 22-ft. cattle waggon with drover's compartment would have in most instances a journal 4 in. by 10 in.

Taking the fixed axle, pony vehicles are mounted on an axle of 1 in. diameter, the axles of broughams and landaus average 1½ in. and 1¾ in., while a drag needs a 2-in. axle to support its heavier load. Vans are fitted with drabble arms according to the weight carried. A ton requires a 1½-in. drabble, while 5 tons finds the diameter increased to 2½ in.

The tram and railway axle is distinctive, owing to its plainness. After leaving the wheel bearing,

these axles are tapered down towards the centre. A 5-in. journal will have a 6¼-in. wheel bearing with 6½-in. collar and a taper to 4½ in. at the centre of the bed of the axle.

In stationary types there are the Collinge, mail, and common axle; drabble arms come under the last heading.

**The Collinge Axle.** The Collinge axle [51-53], which predominates in private carriages and light four-wheeled vans carrying from 10 to 15 cwt., was invented in 1787, and is still the best carriage axle. Its special features are the presence of the left and right-handed nuts and collet found on the extremity of the arm, and the head of the box which fits into the collar. The arm is always cylindrical and not conical, and has an oil groove running along the length of the arm from the collet for about three-quarters of its length. This groove is for the purpose of retaining a quantity of oil at the top of the arm while the wheel is revolving. The last inch or so of the arm, as it approaches the collar, is swelled out somewhat larger, and is known as the *cone*. Around this is another oil groove, which lubricates the arm at the collar, and is

kept supplied from the reservoir in the head of the box. The nuts and collet are usually of gunmetal. After removing the brass axle-cap, which is an ornament, lubricator, and dust excluder combined, we find a split pin, which is a safeguard, and not a means of retaining the wheel under normal circumstances. Then we find the left-handed nut locked to the right-handed nut, which in its turn bears against the collet. The gunmetal collet bears upon the flange of the iron axle-box, and, as they are dissimilar metals, friction is to some extent reduced. The collet is prevented from turning

by having its centre cut out flat on one side, the arm being similarly finished to receive it. The axle-collars and the flaps for attaching the springs are of superior strength when forged in the solid with the rest of the axle.

**Parts of Collinge Axle.** The parts of the Collinge axle as illustrated [51-53] are as follow:

51. COLLINGE PATENT AXLE, WITH SECTION THROUGH STOCK AND AXLE-BOX

DETAILS OF COLLINGE AXLE  
(For details see text)

**The Mail Axle.** The mail axle [50] is the type used in sporting and heavy carriages, and also in fire-engines, carts, and light vans. In the event of the arm breaking in front of the collar, the wheel is retained by the three or four long bolts which pass from behind the collar to the front of the stock, and form the most striking feature of this class of axle. The head of the axle-box fits over the collar and not into, as in the case of the Collinge; also the end of the arm is quite plain, as the duty of the nuts in the Collinge is here relegated to the long bolts. The same cone and oil grooves may be noted, and the arm is also cylindrical.

The details of the axle shown in 50 are as follow:

- |                       |  |
|-----------------------|--|
| A. Axle-arm           | E. Oil groove in collar                    |
| B. Cone               | F. Leather washer plate (split to slip on) |
| C. Oil groove in cone |  |
| D. Collar             |  |

- |  |                              |
|--|------------------------------|
| G. Leather washer                          | M. Front stock hoop          |
| H. Axle-box                                | N. Hind stock hoop           |
| J. Cap                                     | O-P. Centre line of axle-bed |
| K. Long bolt (1 of 3) retaining wheel      | Q-R. Centre line of axle-arm |
| K1-K2. Centre line of other two long bolts | S. Leather washer            |
| L. Stock                                   | T. Leather washer            |

**The Common Axle.** The common axle of the wheelwright has no particular feature, as it follows both the Collinge and mail patterns. It always has a nut and pin, and is never secured by long bolts. The box fits both over and into the collar, according to the variety. The arm is generally conical. The axle-cap may screw into or over the end of the box. Sometimes a single nut provided with a flange, which adds to it the functions of a collet, is used. The *drabble* is used as an arm or as a complete axle. The

two arms, and sometimes the arms and their bed, are fixed to a wooden bed. The common axle has a conical arm, and the outer-pin is often placed through the nut. It finds favour in all classes of vans.

**Ackermann Axles.** The Ackermann axle is a form of axle in which the carriage is turned by means of a pivot behind the collars on the front axle, giving the advantages of a low hanging body easy to enter. It also provides a means of steering a motor-car in which the engine occupies a very accessible position, which otherwise would be taken up by a wheel-house or arch. Discarded by the coachbuilder, the motor engineer saw in it a most useful component part of his under-carriage. A live axle in an automobile is one connected to the motive power at one end and the driving road wheels at the other. It generally rotates in an outer

casing to which the springs, and consequently the motor body, are fixed. Ball bearings are used in carriage axles, but especially in motor-car work and in cycles. Leather washers of best washer butts only are used to prevent vibration and escape of oil, and to minimise the wear at the bearings.

**Manufacture of Axles.** The manufacture of a Collinge axle will indicate the processes adopted in other types.

Carriage axles are made in halves and afterwards welded or shut up to the required length. After being formed either from the bloom or fagoted, the arms are pitched to correspond approximately with the dish of the wheel. The arm is turned in the lathe, a process which necessitates turning up the end of the bed to counteract the pitch of the arm [54]. The ends are then screwed for the left and right handed nuts and the bearing formed for the collet. The case-hardening is then proceeded with, and, when finished, the case-hardened surface should suffer no impression from a new file. After being subjected to a heat for five or six hours, the iron box used in the furnace is removed and the arm plunged into clean cold salt water, then taken out and allowed to cool thoroughly. The arm is again put into the lathe and polished with oil and emery. The interior surface of the axle-box, having been case-hardened, has to be ground on, the arm being damped with oil and emery for that purpose.

54. AXLE BENT FOR TURNING IN LATHE

The grinding is gradual in the direction of the length of the arm, and the operation is effected from the collet bearing towards the collar. The screwed ends are "let down"—i.e., softened by heating,—and the holes are drilled for the split pin, and for the clips in the flaps. The whole is fitted up and lubricated, and the box revolved round the arm at a higher rate of speed than it would attain in actual practice, and after a severe test it is taken apart and examined to see if any undue friction has been set up in any part.

The manufacture of an axle-box is very similar, especially in the finishing processes. The cast-iron variety is made by pouring hematite into sand moulds with cores of dried loam.

A good axle lubricant must endure friction without change of form, and should not possess any acid reaction. It must not thicken and, if a grease, must liquefy easily.

**Journal Boxes.** The journal or axle-box is made of cast iron, although cast steel is being introduced with some success. Wrought iron in this capacity has been found too expensive.

This box encloses the arm or journal of the axle, and, what is very important, contains the lubricating medium. Grease has been largely used in railway work, but in the new types and in passenger carriages both on road and rail oil lubrication is widely adopted, and is found more efficient.

**Springs.** We have noticed the varieties of springs under the heading of Under-carriages. Some types of Army vehicles have no springs, owing to field conditions of active service, while others have springs only under the driving-seat. This latter form of suspension is seen in cycles also. Pneumatic tyres greatly aid in destroying vibration, while in some forms of trucks, as, for instance, wheelbarrows and sack trucks, the size and nature of the conveyance makes the provision of a shock-absorbing medium unnecessary.

All types of springs may be said to have evolved from the elbow spring, although some may regard this as too broad a statement.

**Elbow Springs.** Certainly the elbow spring was the first type used in carriages. It is a laminated spring, the shape of half an archer's bow laid horizontally. It has the load at one end and the support at the other. It is now seldom used alone in carriages. The front attachment of the body to the shafts in a Tilbury gig is, however, an example. Milk perambulators are often hung on two elbow springs.

In combination, it is a part of the hind suspension of the Tilbury and of a mail phaeton, where it connects the body with a hind cross spring, and in other four-wheeled carriages it is attached to the pump-handles at one end and at the other to the end of a side spring, which is shackled to a cross spring. The combination of an elbow and side spring is called a three-quarter elliptic—a type favoured in some of the 1906 motor chassis.

**Side Springs.** In the shape of the entire archer's bow, we have the side spring, which generally has the weight at each end and the support on the axle flap in the centre. A side spring as it plays under the load increases the distance between the spring eyes measured in a straight line. Therefore, we must not fix both ends rigidly. For this reason a shackle is fitted which allows of the necessary working, and it should be attached so that, when the vehicle is weighted with its maximum load, the straight line drawn through the shackle centres shall not be beyond the vertical. The side spring is largely used in the front and hind suspension of automobiles, medium and heavy vans, two-wheeled carriages, and in the hind suspension of some four-wheeled carriages, such as waggonettes, brakes, and omnibuses, where there is a comparatively heavy direct load above the hind axle.

It is a type at present predominating in British railway rolling stock, and is seen under many kinds of barrows and trucks, such as delivery carts, ice-cream and bakers' barrows, and tricycle carriers.

**Elliptic Springs.** The invention of the elliptic spring by Elliott, in 1805, provided an easy and cheap mode of hanging the body, although it cannot be considered an improvement on the C spring. Its commercial success was, however, at once assured by the saving of weight and cost. It is to be found both in English and foreign railway bogie trucks, in the front suspension of light vans, less seldom in the hind suspension, and in most four-wheeled

carriages, especially in the fore-carriage. The gears of the light American carriages are made up with this shape of spring, and are placed either parallel or transversely to the length of the body.

Being more costly than the side spring, it does not find so much favour in trucks and hand-carts, although corn chandlers' barrows and invalid chairs are instances where it is often fitted. The elliptic spring is sometimes used in two-wheeled carts, and it is the type adopted under the driving-seat of Army waggons. In all the cases enumerated, it will be seen that the load is directly over the support.

**C Springs.** The C spring already noted in under-carriages has the same distribution of weight and support as the elbow spring, but differs in shape. The weight of the body on the braces tends to pull them inwards, and it is on the presence of these leather straps that the greater part of the case depends.

**Spring Manufacture.** Springs are made from a specially manufactured steel. Many are made by hand, but the use of machinery is on the increase. Spring steel must be strong, tenacious, and elastic. It must be ductile, so that the ends of the plates may be drawn out. We cannot put on the spring heads if the metal is not weldable, and the ability to be hardened and tempered is essential if a spring is to do its work properly. When broken, it should present an even texture, and must stand hammering without splitting.

The dimensions of the spring being given—its length, the compass or distance out of the straight line, and the load it will have to bear—the smith, in cutting off his plates, has to allow in the back plate for upsetting or thickening the ends, in order that the heads may be put on. In the bottom back plate, which comes next, he rolls the eyes and fits them into the heads. The remaining plates, down to the short plates, are all cut off in decreasing lengths. The plate is cut shorter than its finished length because we have to allow for lengthening or drawing out under the hammer. This is the opposite process to upsetting. The short plate must not be made too stiff, so an extra  $\frac{1}{4}$  in. on each side is cut off before the drawing out. The drawing out adds about  $3\frac{1}{2}$  in. to the overall length of a plate. Drawing out is effected in most coachbuilders' shops in a hollow fire, and the necessary exertion required by the smith and his mate is considerable in drawing, say, a set of four elliptic springs with 36 plates having 72 points. This laborious procedure has been supplanted to a degree by eccentric rolls, worked by machinery, but many affirm that the hand-made spring is the better. Likewise, the spring heads may be manufactured with stamps and dies, and then welded on, which will be successful if both head and plate are of the same welding heat.

The plates having been slotted in the same heat as the drawing, care being taken not to flaw the steel, the middle holes are punched and

the edges of the plates rounded. The slot is cleaned out with a slot file, and into every slot the stud of an adjacent plate fits, the slot allowing of motion between the plates as the spring gives up or down; and in this manner, together with the centre rivet or bolt, the whole is kept together, and the various parts work parallel.

**Tempering and Fitting.** The plates are first hardened by plunging them when hot into a butt containing about 60 gallons of water, which should not be quite cold, and the tank should be large enough to take a whole plate comfortably. Such a process makes the steel extremely hard, and if left in this condition it would be far too brittle. So it is "let down" again by reheating to a certain lower temperature until it ignites a piece of ash stick. This is the tempering, the plate being allowed to cool gradually. In bending the plates to the required arc, we give the upper one a curve a little sharper than the one beneath it, and care must be taken to get the long plate right, otherwise our error will be magnified before we arrive at the short plate. The viceman is called upon to see that the edges of the plates are all flush, and he finishes off heads and eyes, fitting them carefully, having greased between the plates before finally putting all together. He should exercise his discretion in the amount of lubricant he places on the plates for the dual service of preventing rust and friction, for when bolted or riveted up a thin edge of grease is liable to work out on the freshly painted spring when mounted and working under the body.

**Tools.** Swages or top and bottom tools, punches and chisels, are among the tools which are often made by the smith himself. They should be steel-faced. The bottom tool is capable of fitting to the anvil, while the top tool is held by the smith in a handle generally made of a twisted hazel rod.

**Fitting.** The coachsmith has many different plates and pieces of ironwork to fit in a vehicle body, the most important being the edgeplates. Care must be taken not to fit too hot, or the framework will be charred and the joints opened. Although usually made of iron, edgeplates, when of mild steel, can be made of smaller dimensions, as the material is more rigid. A smith will sometimes argue against the use of steel, chiefly because of the extra skill and labour required in welding up the different sections. The fixing of the plate may be with bolts or screws, according as the framework allows, but we must see that the bolt-holes are tightly filled, and when the boot side, rocker, or other parts of the timbers traversed are of hard wood, there will be no necessity for jaggings, as is sometimes done.

The smith is one of the most skilful artisans in the shop, and his rate of pay at least equals that of the bodymaker, although it does not exceed that of the motor body metal plate worker.

## THE DOUBLE-ACCOUNT SYSTEM

Debentures. Terms of Issue and Redemption. Parliamentary Companies.  
Income Tax Assessment. Exemption, Abatement, and Repayment

By J. F. G. PRICE

WHEN a dividend is declared by a company a dividend account is opened and credited by the amount to be paid, the profit and loss appropriation account being debited. As the dividend is paid the dividend account is debited and cash credited. The dividend is always calculated upon the amount *paid up* on the shares, and the forfeited shares do not participate.

The appropriation of profit account, given below, and the liabilities side of the balance sheet, shown on the following page, are suitable for the company whose opening capital entries have been already given and explained. There is one item in these liabilities which requires some explanation.

**Loans on Debentures.** Limited companies frequently avail themselves of the facilities afforded by debentures to borrow money for the purpose of acquiring or carrying on their undertakings. Debentures are of two kinds: (a) those which are a mere acknowledgment of money lent; (b) those acknowledging a loan and giving a charge or mortgage upon the company's property as security for the repayment of the sum advanced. Both kinds are given under the seal of the company, and carry interest at a fixed rate during the time the loan is outstanding. The latter class are by far the more numerous, and, by reason of the security which they give, are a favourite form of investment with the capitalist who is content with a smaller return for his money than he might look for from shares. They are known as mortgage debentures, and are the kind here dealt with. Debentures may be either redeemable at a fixed date or they may be irredeemable.

The difference between a debenture and a share is of the utmost importance. The holder of the former is a creditor of the company for the amount of his loan, and is not merely an ordinary creditor, but one holding security for payment of his debt. If the company fails to pay interest on the due date, or if it defaults in repayment of the

principal at the stipulated time, or is wound up, the debenture-holders usually have a right to take possession of the property and realise it for the purpose of satisfying their claims. After they have been paid, any surplus would belong to the ordinary creditors of the company, and the shareholders would be entitled to anything there might be left only after these claims have been discharged. The debenture-holders, therefore, come first, as secured creditors, the shareholders last, as proprietors of the concern.

**Issue at Premium or Discount.** Invitations are often given to the public to subscribe for debentures in the same way as for shares—viz., by means of a prospectus. The procedure as to application and allotment is practically the same as in the case of shares, and the entries in the company's books are very similar. The broad result is the debiting of cash with the amount received, and crediting a "Debenture Account," instead of a share capital account. A register of debentures is kept, which is ruled in very much the same way as a register of members and share ledger, the headings being altered to correspond with the different circumstances. Debentures may be issued either at par, at a premium, or at a discount, and may be redeemable either at par or at a premium. If they are issued at a premium, the extra amount received will be debited to cash and credited to a "Premium on Debentures Account." The amount of the premium will represent a gain to the company, for there will be no liability to the debenture-holders in respect of the sum paid in excess of the nominal amount of the debentures. The premium is the bonus the applicant is willing to pay in order to become a holder of the debentures. It cannot be distributed by the company by way of dividend, but is either treated as a reserve fund or used in reduction of any preliminary expenses the company has paid in establishing the business.

| Dr.              |   | PROFIT AND LOSS APPROPRIATION ACCOUNT |         | Cr.   |            |
|------------------|---|---------------------------------------|---------|---|------------|
| 1908.<br>Dec. 31 | To Interim Dividend paid on Ordinary Shares for half year @ 8 % per annum .. ..                     | 190 0 0                               | June 30 | By net Profit from Profit and Loss account.. .. | 1,456 9 8  |
| 1907.<br>June 30 | „ Reserve Fund. ..  | 500 0 0                               |         |   |            |
|                  | „ proposed dividend on ordinary shares for half year @ 12% per annum, making 10% for the year .. .. | 295 0 0                               |         |   |            |
|                  | „ balance forward ..  | 481 9 8                               |         |   |            |
|                  |   | £1,456 9 8                            |         |   | £1,456 9 8 |
|                  |   |                                       | July 1  | By balance c/f .. ..                            | £481 9 8   |

If, on the other hand, the debentures are issued at a discount, the company will, of course, receive something less than the full amount for which it will be liable to the debenture-holders, and the amount it loses on the transaction is debited to a "Discount on Debentures Account." The full entries are: (1) A debit to cash of the amount actually received; (2) a debit to discount on debentures account of the difference between the amount received and the full amount of the debentures; and (3) a credit to the debenture account of the nominal amount of the debentures. The debenture account will always have the latter amount to its credit, whatever the terms upon which the debentures have been issued, and this will be the amount of the liability upon the head of debentures in the company's balance-sheet. The debit on the discount account must be written off to profit and loss account by the time the debentures become redeemable.

**Redemption of Debentures.** When debentures are redeemable at a fixed date it is necessary for the company to make provision for paying them off when the time arrives—unless it is in a position to re-borrow the money on favourable terms. One method of doing this is for a sinking fund to be created in the manner previously described in connection with a wasting asset, so that the company's resources shall be equal to the demand when the time arrives for payment. If the debentures are repayable at a premium, care must be taken that the instalments set aside and invested periodically are sufficient to accumulate enough to pay both principal and premium. Other methods of providing for the payment of redeemable debentures are: (1) The purchase of debentures on the market if the price is favourable; or (2) the taking out of a policy of insurance for an amount sufficient to repay the debentures at the due date. Under the latter method the amount of the premium would represent the sinking fund instalment; there would be no risk of loss from the depreciation of the sinking fund investments, and the company would be saved the trouble of periodically investing the instalments and the accruing interest.

**Annual Summary of Capital.** Every limited company having its capital divided into shares is required to furnish each year a summary of its capital and return of its members in a form prescribed by the Board of Trade. The particulars comprise the nominal capital and how it is divided, the number of shares taken up—distinguishing between those issued credited as fully paid, and those to be paid in cash—the amount per share called up, and the total sum

|                                      |               |        |    | £13,248 8 7 |

received, the total amount credited as paid on the shares not issued for cash, the amount of unpaid calls, and the amount received on forfeited shares. The summary must give the amount of debt due by the company in respect of debentures and floating charges on its property. The name, address, description, and share holding of each member must be given in detail, as well as a list of the directors.

Besides companies limited by shares, there is a class of company in which the members do not contribute the capital during the company's existence. This kind of company is useful in concerns of a non-trading character, such as professional societies and chambers of commerce, where incorporation is desirable but no working capital is required. These companies are said to be limited by guarantee, because the members guarantee to subscribe a certain limited amount for the purpose of paying the debts if the company be wound-up. There is no peculiarity in the accounts of these companies calling for notice here.

**Double-account System.** In addition to companies incorporated under the general Companies' Acts many companies are brought into existence by special Act of Parliament. These companies are, as a rule, formed for the purpose of carrying out works of a public nature such as railways, gas and water works, canals, electric light and power undertakings, etc. For such companies a special system of accounts has been laid down, which is known as the double-account system. It must not be supposed by the reader that this is another name for the double-entry system. All our accounts so far have been upon double-entry principles, and the double-account system is merely an adaptation of those principles for the purpose of showing

## CLERKSHIP

clearly a certain set of facts. It has been sufficient hitherto to state the whole position of a firm or company in a single statement called a balance-sheet, which includes the whole of the assets and liabilities of the concern of whatever sort or kind. Accounts kept on those lines are said to be kept on the single-account system, since one account shows the whole position, but this must not be confused with the so-called "system" of single entry.

From the nature of the companies named above it will be seen that their objects are the construction or acquisition of particular works which, when acquired or constructed, will be used for the purpose of earning revenue for the proprietors. They trade in a sense, but not by buying a commodity at one price and selling at another.

**Capital Account.** The particular object of the double-account system is to show clearly the amount of capital that has been raised for

coals, coke, tar, and other products, debts due from persons to whom gas, coke, etc., have been supplied, and any other assets, other than the fixed assets, which the company may possess.

**Revenue Account.** A detailed revenue account is prepared showing on the one side the income arising from (1) sales of gas; (2) sales of residual products, such as coke, tar and breeze; (3) rents; (4) other items, such as fittings, discounts, etc. On the debit side appear the various expenses under the heads of (1) manufacture of gas, including materials, wages, repairs, etc.; (2) distribution of gas, including salaries, repairs of mains, pipes, and meters; (3) rent, rates and taxes; (4) management expenses and, lastly, miscellaneous items.

The effect of this arrangement of the capital account and the general balance-sheet is that it is necessary to examine both those statements in order to obtain full information as to the assets and liabilities of the concern. Another

the purpose of the undertaking and how that amount has been expended upon purchasing or constructing the fixed assets—i.e., the property which will, subject to wear and tear and depreciation, always exist for the purpose of earning revenue. With this object a statement is prepared in tabular form showing the character of the capital raised and the manner in which it has been applied. The above is a specimen of such a statement in the case of a gas company, and will enable the reader to see how the object of the system is attained.

Only the balance of this account is carried into the company's general balance-sheet, which also shows, on the liabilities side, the amount to the credit of the profit and loss account, the reserve fund, the depreciation fund (which will be explained later), and the general floating liabilities of the company. On the assets side appear the floating assets of the concern, such as cash in hand and at the bank, the stocks of

result of preparing accounts on this system is that the fixed capital assets are shown at cost in the published statements instead of at their actual values. Any repairs and renewals are made out of current revenue and not out of capital moneys, while any extensions and additions are properly provided out of money raised for the purpose and charged as capital outlay in the capital account, as shown above.

**Depreciation Fund.** Although the fixed assets are set out in the capital account at cost, proper provision is made for wear and tear and depreciation by an amount being charged annually in the profit and loss account in this respect. The amount is not written off the book value of the assets but is carried to the credit of a special account entitled "Depreciation Fund Account," or some other equally distinguishing title, and included in the general balance-sheet under that head. The effect is that, taking the capital account and the general

balance-sheet as a whole, the position of the company is accurately stated; as, although the assets are shown at more than their actual value, this is rectified by the inclusion on the liabilities side of the amount of the depreciation which has taken place and which would, in accounts kept on ordinary single-account (not single entry) lines, be deducted from the assets on the other side of the balance-sheet.

**Fixed and Floating Liabilities.** Attention has already been directed to the fact that the assets may be divided into two classes—viz., fixed and floating assets. The separation of the capital account from the general balance-sheet, which takes place under the double-account system, emphasises the fact and further makes it clear that a similar division may be made in the case of the liabilities, those of a fixed nature being the share capital of the concern and loans on debentures or mortgages, while the floating liabilities are those to creditors supplying stores, materials, etc., or for unpaid dividends or interest, the indebtedness to whom is discharged practically immediately.

It may be stated that the broad principle of the double-account system is the division of the assets and liabilities into two classes—fixed and floating—the former being included in the capital account, the latter in the general balance-sheet.

**Capital and Revenue.** A further point to which attention is drawn by the double-account system is one not specifically dealt with hitherto; that is, the distinction between capital and revenue items. The receipts of a business are generally of such a nature that their classification is an easy matter, and the distinction is quite apparent; but in the event of there being a doubt as to the nature of a particular item, it must be carefully examined, and credit must not be taken for it as income unless it is clear that it can fairly be regarded as revenue of the concern. The question whether an amount should be treated as revenue or capital usually arises in connection with expenditure. The principles upon which a decision should be come to are quite clear, but their application is sometimes a matter of some doubt. The broad rule is that expenditure on the acquisition or construction of property which is to be used to earn revenue, or expenditure which adds to the value of property already acquired is capital expenditure, and may be debited to an asset account, while outlay, such as repairs and renewals, which merely maintains property at its book value cannot be so treated, but must be regarded as an expense of carrying on the business. The question frequently arises in connection with the purchase of new plant or machinery which may be either wholly or in part in replacement of old assets of the same nature. So far as the new plant, etc., is in replacement of something already standing in the books as an asset, the cost must be treated as a revenue charge and debited to the profit and loss account; but if any part of the expenditure is upon additional plant which will increase the actual value beyond the amount appearing in the books,

the proper course is to debit such increase to the asset account, and not allow the charge to fall against revenue.

With regard to amounts received, any doubts concerning their nature will probably arise in connection with the sale of part of an asset. For instance, a patent may be standing in the books of a concern at its cost of £500. A half share is sold for £1,000. There are at least three ways of dealing with this transaction. One is to write off the whole cost of the patent and treat only £500 of the sale price as profit. The second is to retain the remaining half at its present value of £250, and treat £750 of the price as profit. The third method would be to treat the second half as worth as much as the first had sold for, and increase its value in the books accordingly. The result under this method is that credit is taken for the whole £1,000 received for the half-share, and for a further £500 in respect of the increased value of the remaining half. This is not desirable, and the fairest basis is the second method.

**Income Tax.** A matter that is a cause of some worry and annoyance to a trader or to the secretary of a trading company is the annual return to be made for income tax purposes. Income tax is a charge levied annually upon net profits derived from sources in the United Kingdom or paid to residents therein. It is intended to be charged on income from all sources, and the various kinds of income are classified under schedules distinguished by letters of the alphabet. Thus, Schedule A relates to income derived from the ownership of land and buildings, and is borne by the owner although paid in the first instance by the occupier. It is known as the property or landlord's tax, and when collected by the authorities from a tenant may be deducted by him from his next payment of rent. Schedule B is borne by the occupier and relates to the income from farms, etc. Schedule C has reference to income from public funds, and is generally deducted before the income is paid to the recipient. Schedule E relates to salaries and emoluments paid to persons in the employ of the State, public bodies, companies, etc. Schedule D is the important schedule from the point of view of accounts, since it relates to the profits arising from the carrying on of trade, manufacture, and business generally. The rate of the tax for each schedule is so much in the pound, and is fixed annually by the Finance Act. The amount of tax payable depends upon the amount which has been fixed by the surveyor of taxes as the income of the trader for a particular year. The amount of income is fixed, or, as it is termed, assessed, upon the basis of a return which has to be made each year in or about the month of June. The tax is payable annually on January 1st and is in respect of the year ending on April 5th following.

**Assessment under Schedule D.** In the spring of each year a form is sent by the local assessor to persons and firms in his district requiring them to make a return of their income for purposes of assessment. When

## CLERKSHIP

returning the form the trader has to make a declaration that the amount stated as liable to tax is correct. The penalty for making a false return is £20 and treble the duty chargeable. The amount returned is based upon the average of the three complete years preceding the year of assessment. Thus, in making a return for the year 1906-7—i.e., ending on April 5th, 1907, a trader whose books are balanced on June 30th in each year would base his return upon his profits for the years ending June 30th, 1903, 1904, and 1905 respectively. Where a business has not been carried on for as long as three years, the return will be based upon the period during which the business has been established.

Towards the end of the year the surveyor issues the notices of assessment. They are sent to all affected persons in his district whether they have made returns or not. If the amount at which the trader is assessed agrees with the amount he returned, he need take no steps, but will wait until he receives a demand for payment, about December, and then pay the tax. If, however, the assessment exceeds the amount on which he considers he should be called upon

to pay, he must take steps to appeal to the income tax commissioners. To do this with any hope of success he must be prepared with accounts substantiating his contention as to the proper amount of his income, and he should also be ready to produce his books if required; for, although their production cannot be enforced by the commissioners, a refusal will probably result in the surveyor's assessment being upheld. The return originally sent in should, of course, have been made from accounts prepared for the purpose, and if that was the method adopted those accounts should be forwarded to the surveyor. It may be that he will be satisfied with the production of the accounts. If he is, no further attendance will be necessary, for he will arrange with the commissioners for a reduction of the assessment.

**Accounts for Surveyor.** It is obvious that a trader will be well repaid for the careful preparation of his accounts for income tax returns at the outset. In order that the accounts shall be prepared upon a proper basis it is necessary that he should know which items in the nature of expenses will be allowed to be

The profits of John Smith, an ironmonger, as shown in his books were, for the year 1903, £863; 1904, £210; 1905, £587.

£1,261 + £606 + £977 = £2,844. Average liable to tax £948.

deducted from his trading profits and which will not, for some of the charges properly made by a trader when preparing his profit and loss account and arriving at his net profit are not allowed to be charged for income tax purposes. On the other hand, there are a few items of profit or income which a trader need not bring in to his account for those purposes. Speaking generally, all charges and expenses necessarily incurred in earning the income of a concern are allowed, but nothing else.

The following are some of the principal items not allowed to be deducted from gross profits in arriving at the taxable income: 1. Losses not arising from trading. 2. Interest on capital. 3. Partners' salaries. 4. Interest on loans. 5. Ground rent. 6. Depreciation of land, buildings, leases, patents. 7. Income tax. 8. Reserve and sinking funds. Tax should be deducted from items of the nature of 4 and 5 when paying the amounts, the effect thus being that the tax is actually borne by the recipient of the payment.

The following items, *in addition to the usual trade charges*, are allowed: 1. If the premises are the freehold of the trader and, therefore, no rent is paid, he is, nevertheless, allowed to debit the amount of the assessment, the reason being that he has already been charged tax under that head on Schedule A. 2. Repairs as distinct from additions. 3. Estimated doubtful debts. 4. Life insurance premiums up to one-sixth of income. 5. Loss of stock by fire, after taking into account compensation received from an insurance company. 6. Bank interest and charges, because the banker pays the tax. With regard to rent of the trade premises, when they are not his own, he is allowed to charge the amount of the net assessment under Schedule A whether it is in excess of the rent actually paid or not.

Wear and tear of plant and machinery is also allowed, and the rate of allowance is in the discretion of the surveyor. It has already been pointed out that "depreciation" and "wear and tear" are not synonymous terms, and this must be remembered for income tax purposes, as only the latter is allowed. It must be borne in mind that the items enumerated are not the only charges that are allowed. They have been specially mentioned because of their slightly exceptional character, but all losses and expenses necessarily incurred in carrying on the business may, in ordinary circumstances, be charged.

**Exemption and Abatement.** Two further points should be mentioned before proceeding to give an illustration of the making of a return in a concrete case, (a) the tax is a personal one, and (b) it is levied as far as possible at the source of the income. Point (a) is of im-

portance in the case of a partnership, for certain exemptions and abatements are allowed in respect of incomes under £700 per annum. No tax is payable on incomes below £160. An abatement of £160 is allowed on incomes between £160 and £400—i.e., a person with an income of £350 would only be required to pay tax on £190. An abatement of £150 is allowed between £400 and £500; an abatement of £120 is allowed between £500 and £600; an abatement of £70 is allowed between £600 and £700. Persons with incomes over £700 per annum pay tax on the full amount. As the tax is personal, partners in a firm have the right to be separately assessed. Therefore, in the case of a partnership where the net profits are £1,200 per annum, and there are three partners sharing equally, they will be entitled to be assessed on an income of £400 each, and so entitled to an abatement of £160 each.

**Repayment.** With regard to the second point, as the tax is levied at the source of the income, limited companies earning profits are charged upon the full amount thereof, no abatement being allowed to them. It frequently happens, therefore, that a person who receives his income from investments in stocks and shares, and whose total income is such as to entitle him to exemption or abatement, is in the position of having had tax deducted before his income reached him. In such a case, and, in fact, in any instance where tax has been wrongly paid or deducted, a claim for repayment must be made to the surveyor.

A trader is also entitled to claim repayment if, after having paid tax, it is found that the assessment on which it is paid exceeds both his actual profits for the last complete year of trading—which was not complete when making his return—and also his average for three years, including the last completed year. The amount he is entitled to recover is the difference between the tax paid and the tax on the larger of these two amounts.

An illustration is given on the last page of the manner in which an account is prepared either for return for assessment or for appeal on assessment.

If the account is prepared for the purpose of appeal against an assessment, inquiry should be made of the surveyor as to the method in which he prefers the same to be made up. Some surveyors like to have the profit and loss accounts for the three years as prepared for the business and three additional statements, adding to the net profits such items as have been charged in the accounts which are not allowed for income tax purposes. Others prefer to have a statement prepared for income tax only showing income on one side and all proper deductions on the other. The former method is the one more generally in use.

*Continued*

## PLAIN &amp; FANCY STITCHES

Various Stitches Used in Making Underclothing: Hemstitching, Herring-boning, Feather-stitching, Tucking, etc. Some General Hints

By AZELINE LEWIS

THE stitches most in use in making underwear have now to be dealt with.

TACKING and BASTING have been explained and illustrated in DRESSMAKING [150], and should be done with fine cotton.

HEMMING is one of the most indispensable stitches in plain needlework, as no garment is complete without a hem. It has been illustrated and explained in DRESSMAKING, and for underwear requires to be very neatly done, either by hand or machine. It may be from one-eighth of an inch, such as is used for the edge of a frill, to the one and two inch wide hem at the bottom of a nightdress. The latter width is usual in a fine material to weight it somewhat, but a hem should never be less than one inch wide for a chemise or nightdress, that is, if the former is not adorned with a frill as in the best underwear.

To keep the hem even, the best plan is to have a card nicked [17] to the right width and measure from this from time to time. Remember not to have a knot when starting a fresh thread of cotton. Cut the previous thread within half an inch or so from the end, insert the point of needle just below edge of fold in a slanting position to the right, bring it out over the previous stitch, leaving an end of thread; then tuck both ends neatly under the hem to the left and continue hemming as before, when the joining of cotton should not be visible. Finish off firmly, and slip the needle under the hem before cutting off the cotton.

RUNNING has also been described in DRESSMAKING, and is required chiefly to join a seam together before felling. It must be very neatly and evenly done.

SEAMING, or SEWING. This is a sort of fine overcasting stitch used to join two selvages together. The two edges to be joined should be placed evenly together, edge to edge, and pinned or tacked at short distances to keep them from getting puckered, which is very likely to happen if this is not done, unless the worker be very expert.

Hold the work upright in the left hand between the thumb and forefinger, and round the tip of the latter, and work from right to left. The stitches should only be deep enough to just hold the selvages together, and should lie in a slightly slanting direction, and be not more than three threads from each other. No knots are allowed in seaming. Place the needle with the fresh thread (having cut the former as directed for hemming) a little to the right, bring out over last stitch and sew over the threads with the next few stitches, cutting off any ends that project. When the seam is

finished, place the finger under the seam and flatten it down with the thumb-nail, or it may be placed, if preferred, on the table and flattened with a short bone paper-knife or tooth-brush handle [2].

For a *seamed* fell turn in the raw edge of one portion  $\frac{1}{4}$  in., then turn in the other double this width, because the one half is turned back for the fell. Place the fold of the turn-down to the second fold of the other edge and seam together; then flatten and fold back the turned-down edge and either seam or fell this down, thus making a nice neat seam [7].

OLD GERMAN SEAM. This is much the same stitch as fine drawing, so much used by tailors, and was largely used in old linen work. The seam sketched is very useful for joining two selvages together, if the material be somewhat thick, as some makes of linen [9]. The stitches are taken first on one side and then on the other within the selvedge, and only two threads apart, with the needle towards the worker. The cotton must be drawn till the edges meet closely but do not overlap, when a perfectly flat seam without any ridge will be produced. The edges must be marked at regular distances and the marks kept level to prevent the seam becoming puckered.

FELLING, or a RUN-AND-FELL SEAM. This kind of seam is usual for joining the various portions together. Fold down one edge  $\frac{1}{4}$  in. (or a little more or less according to the material and garment), place the corresponding edge of the garment to the turned-down edge, a shade below the fold, then tack and run, or machine together; remove the tacking and fell down neatly, being careful to keep the under edge quite flat and level with the running, and not letting this turn into a fold. These seams should correspond or pair with each other—that is, if the first one be begun at the top of the garment, the other should be started at the bottom; this will make all the difference between a well-arranged and a faulty garment [8].

STITCHING. See DRESSMAKING and TAILORING.

HEMSTITCHING. Though hemstitching is usually employed for handkerchiefs, the stitch is a useful one, and of late has been called into play in tucking, which, instead of being merely run, may be open-worked at the upper edge, and thus made much more ornamental. For a hem, begin by drawing out two threads of the material,  $\frac{1}{4}$  in. from the margin and 2 in. or 4 in. at the distance from the margin the hem is required to be. Fold over the turn-down of the hem even with the drawn-out threads,

1-16. PLAIN AND FANCY STITCHES

## DRESS

then fold up the hem to the second row of drawn-out threads, letting the edge lie perfectly level with the lower edge of the threads. Tack along, then thread the needle, insert it in the fold, as in the diagram, bring it out three threads above the fold of the hem, insert the needle between the open threads immediately under the place where the cotton is emerging, and, passing it to the left, take up three open threads on the needle and draw the cotton through. Insert the needle again in the same place, and now, turning it in a slightly upward direction through the hem, bring it out above the place where the cotton now appears—that is, three threads above the fold of the hem and three threads to the left of the previous stitch; draw cotton through and proceed in the same way to the end of the drawn threads [6].

17

For a tuck, the threads are drawn and the inner fold of the tuck placed to the first of the drawn threads, when the stitches will be done in exactly the same way as for the hem. In these tucks, however, it is usual to work the other edge of the drawn threads in the same way as the hem, which makes a very pretty finish and is much used in underwear, baby frocks, cambric blouses, etc.

**WHIPPING.** This stitch is indispensable for fine underwear, and is used for uniting lace or insertion to the edges, gathering for openwork insertion, and a variety of purposes. A whipped hem is formed in this way. Take the edge of the garment, cut it perfectly level, just moisten the left finger and thumb and roll the edge downwards until it forms a tight and very narrow rolled hem. This requires some little practice to get even and not stretch the edge. When a sufficient edge has been rolled—and it must be worked till it is quite narrow—place the edge of lace to this underneath, and secure to the edge by a fine overcasting stitch, taking it under the whipped edge, so that this is enclosed and no raw edges are visible [14]. If properly done it should form only the very narrowest sort of corded edge, and in very fine work be scarcely seen. When sewing on gathers of fine material to a transparent insertion, the edge should be whipped and then gathered by the overcasting stitch mentioned [1]. If the material be somewhat thicker, the edge should be turned in about  $\frac{1}{4}$  in. and then gathered, as this will be less clumsy than whipping it first.

In veining the seams of under-bodices, for instance, the edges of the material and beading are both whipped very finely and oversewn with the finest of cotton.

**HERRING-BONING.** The method of working this stitch has already been explained, and illustrated in DRESSMAKING. It is required in flannel work for seams—and sometimes for hems—to obviate the hard ridge which would be caused by turning in the edge again as in the usual method. Very fine cotton or silk should be employed, and the stitches worked very evenly and closely together, just far

enough from the raw edges to keep this neat, but not large enough to be unsightly. For a flannel seam, cut the edges perfectly even, place one edge nearly  $\frac{1}{4}$  in. below the other, and run the two edges neatly together about the same distance below the inner edge; but these distances must depend very much on the garment and the material and the judgment of the worker. When run together, turn the upper edge down over the lower and herring-bone along, being careful to keep the seam even. If this is done there should be no ridge, as would be the case if the two edges were put quite evenly together [16].

If the flannel be rather thick the hem may be herring-boned down raw-edged instead of being turned in. This is an important point to be remembered in flannel work.

**OVERCASTING.** [See DRESSMAKING.] Use fine cotton, and remember not to pull the thread tightly.

**GATHERING.** [See DRESSMAKING.] For underwear, the addition of "stroking the gathers" is needed to flatten them and make them more easy of manipulation. To do this, when the gathers are finished draw them up closely, leaving a little space to work them forward, and secure them round a pin [11]. Keep the right side of the work towards you, take a strong needle, and, holding the work between the forefinger and thumb of the left hand, the latter being pressed below the gathering thread, begin stroking on the left-hand side, working from the top and raising each gather gently with the point of the needle, and work into a little ruck or fold, pressing down under the left thumb till all the gathers lie perfectly flat and smooth in a row. Stroke down each gather level, as far as possible, with the thread of the material.

18

There is, however, another way of obtaining the same result. For this, take a long, strong needle for gathering—that is, a coarser one than you would ordinarily use.

Gather the needle till quite full, keeping the thimble-finger at the eye of the needle, so that no stitches escape on to the thread. When no more material can be forced on, still holding the thimble in place, with the thumb and first finger hold the gathers securely to the needle at the point end. With the left thumb and first and second fingers pull the gathers two or three at a time straight down from the needle with a swinging motion, sliding the fingers under the material and pulling down with the thumb, beginning at the left and working towards the right. When the work is slipped on to the thread it will be found as flat as if each gather had been stroked in place, and thus the two processes of gathering and stroking are practically accomplished at once.

**SEWING IN GATHERS.** When the material is gathered and stroked, loosen the threads and open the gathers, then mark the half and quarters of the band and portions to be gathered, pin and sew in place, distributing the gathers evenly,

and take up one gather with each thread [8]. In elaborate underwear gathered edges are much prettier set in with a beading.

**BUTTONHOLES.** The working of buttonholes has been fully explained in **DRESSMAKING** and **TAILORING**, but 15 shows the usual method of working these in cotton and similar goods, the thread being passed round to the left of the point. It is best for thin materials to overcast the hole somewhat loosely rather than as advised for tailoring.

For underwear the buttonholes may be worked as in *a*, or with one end barred, as at *b*, whilst bars at each end, as in *c*, are only required in perpendicular buttonholes as in fronts of chemises, nightdresses, blouses, etc.

of different widths, in groups, etc., this depending much on the material, garment, and good taste of the worker. When the arrangement has been decided, make a diagram as in 18, so that all may be even. It is well to remember that a tuck always occupies three times its width—*viz.*, the upper and under surfaces of tuck and the width of material it lies upon, and a little clear space has always to be allowed between each tuck. For wide tucks the space may be estimated as half the width of the tuck. Very narrow ones require a greater proportion, at least the width of the tuck, as otherwise they appear overweighted.

**SINGLE FEATHER-STITCH.** This is so useful a stitch that it may be considered indispensable

19-23. PLAIN AND FANCY STITCHES

**SEWING ON BUTTONS.** As explained in **TAILORING**, all buttons should be sewn on with a shank. To obtain this a coarse needle or bodkin should be placed through the first stitch taken when sewing on the button and the remaining ones worked over this. When finished, remove the bodkin or needle, pull up the button shank and twist the cotton round the shank thus formed several times before fastening off [10].

**BLIND LOOPS.** These loops are required for fastening when buttonholes are not advisable or possible, as at the ends of lace insertion, etc. To work, make a loop of several threads of cotton large enough to take the button easily, but not too loosely, then buttonhole round the threads, pushing each stitch close to the other [12].

**TUCKING.** The method of working tucks has been explained in **DRESSMAKING**, but as this is such an important part of the ornamentation of underwear, a few further hints are desirable. Tucks may be arranged in a variety of ways,

in this sort of work. It is done lengthways, with the needle towards the worker. Place the needle alternately right and left when making a stitch in the material, sloping it slightly towards the centre, and making each one slightly lower than the other. Keep the thread to right and left of the needle when working according to the stitch. It must be kept perfectly even and regular, and may be worked with cotton or silk of varying degrees of fineness according to the material [4a]. For the double variety take two stitches to right and left instead of one, as shown in 4b. This must be very evenly worked, and of the same width all the way along. Chain stitch is illustrated in 4c.

**CORAL-STITCH.** This is merely a variation of the above, the only difference being that the stitches are made quite diagonally at right and left, and the needle is always brought out in the centre exactly underneath the previous stitch, thus making a straight line down the middle [5].

**WHEATEAR-STITCH.** This forms a pretty variation of the coral-stitch, and can be either single or double. It is worked with a preliminary chain-stitch, with a diagonal one to right and left from the centre chain [13 and 19].

**SATIN-STITCH.** Now that embroidery plays a large part in the ornamentation of the finer kinds of underwear, being worked on the garment itself, we have included this among stitches necessary for underwear. For this purpose it is not always padded as in embroidery, as this would make uncomfortable ridges and lumps. For monograms, etc., however, the raised portion will require a little padding, as in festooning [21]. It is best to work the stitches in a slanting direction as in the diagram, as they lie better so. Work from you with the thread underneath, and keep each stitch even and close to the previous one [20].

**CROSS-STITCH AND MARKING.** Cross-stitch is not so much used as formerly for marking embroidery, the woven letters and marking ink having taken its place.

Very effective designs for large articles can be worked in chain-stitch, or combined with satin-stitch, these being very easily and quickly done. Elaborate monograms and designs in satin-stitch require a frame for their working.

**FESTOONING.** This is chiefly used to finish off the edge of flannel garments, but with embroidered chemises and camisoles a festooned edge is a necessity, and the accompanying diagrams show the method of working. First mark the scolops, then outline them with fine cotton to keep the two edges together, if a hem, and also to give a little firmness to it.

Diagram 21 shows the scolops padded with chain-stitch in soft cotton and then finished in buttonhole-stitch. For the scolops, transfer papers can be purchased at any fancy-work repository, which only need ironing off; but for the round ones a halfpenny, penny, or any other round object will do to draw the semicircles with.

Diagram 22 illustrates a simpler method of finishing off a scalloped edge for flannel underwear, which is very quickly worked, and quite effective for inexpensive materials. This should be outlined with a rather coarser cotton than for the other way, or can be worked over a thread, and the stitch, it will be seen, is the single wheat-

ear shown in 18. Diagram 23 shows a simple and pretty stitch for the ornamentation of flannel underwear.

**FAGGOT-STITCHING.** For this see DRESS-MAKING

**SEWING IN GUSSETS.** There are two kinds of gussets—square and triangular. The former

are usually employed for the lower parts of chemises and nightdress sleeves, to give a little additional spring. [For the method of cutting see CHEMISE.] The triangular kind is employed to strengthen an opening like those at the lower side of a man's shirt. Diagram 24 shows at *a* the first stage of the gusset, this being cut through the square as in the other shape, and the apex sewn to the point of the opening; *b* shows the second stage, and *c* the gusset inserted and finished on the wrong side.

### Some General

**Hints.** Linen and calico are better washed, stretched, and pressed before being cut out, as this will remove whatever dressing there may be in the fabric, and make it much easier to work. It is also best to purchase longcloth or linen of a close, even make—that is, with the threads of the same thickness in both warp and woof, and also with straight, firm selvages.

Flannel, calico, and muslin may be torn, if required straight, but the process is apt to pull it somewhat. Linen and lawn should be cut by a thread.

Under-garments are cut lengthways of the

material—that is, with selvages going from head to foot, as in chemises and nightdresses.

Collars, wrist, and waistbands, yokes, and shoulder-straps should, therefore, always be cut selvageways, as these are not required to stretch or give, there being more strain on those portions.

Cotton should always be used the way it unwinds from the reel, as the friction of the eye of the needle *against* the fibre or twist of the cotton will sometimes cause it to fray or break.

All underwear is made by means of the foregoing seams, stitches, etc., the number and kind depending on the garment, a run-and-fell seam and hemming being required in all cases. The side seams of nightdresses and chemises, also the leg seams of drawers, are always united by a run-and-fell seam, and a hem must finish off the lower edge of chemise and nightdress.

# THE HARP

Putting on the Strings. The Octaves. Tuning. Correct Attitude of Player. Finger Preparation. Right and Left Hand Practice

Group 22  
MUSIC

23

Continued from  
page 2170

By ALGERNON ROSE

**W**HEN the beauty of outline and charm of tone of the harp are considered, it may seem strange that this instrument is nowadays seldom heard in the home; but let the student who has bought a harp attempt to master it without the assistance of a tutor and he will speedily discover why it was superseded by the pianoforte. A child can go to a keyboard and elicit sounds which are in accord with each other; but with the harp, the player has to tune, and continually to keep in tune, upwards of forty strings. On the first occasion he will probably have to replace several which are broken. It is therefore necessary that the student should appreciate the difficulties which lie in wait for him, and endeavour to overcome them by carefully following the instructions given.

**Stringing the Harp.** It is false economy to get cheap harp strings; only those of the best manufacture should be used. Their tone is of better quality, and, being more evenly graded in size, they last longer. The thickest and longest strings are those nearest the pillar, giving the deepest tone; then they diminish in length and thickness till the high treble notes are reached. Use a gauge to ensure that each size is correct. This can be obtained wherever the strings are purchased.

The first thing to note is that all the C strings are red in colour. All the F's throughout the scale are of dark blue. The other strings are white. This enables the correct notes to be identified rapidly in playing. Beginning at the pillar we have the bass octave, which consists of wire-covered strings. These of good quality cost about 2s. each. In a full-sized Gothic concert harp the strings nearest the pillar are C (red) and D. The old-fashioned single-action harp has a shorter compass of six octaves, from E to E. In that case the longest string would be E, and the next one to it F (blue).

**How to Put On a String.** After unrolling a wire string, see that it is overspun equally. Pass one end of it through the eye-hole in the first "wrest-pin" of the neck of the instrument, and tie a knot securely at that end. Take out the corresponding wooden peg in the sound-board, and pass this end of the string through the aperture. Replace the peg so as to hold it tight, and bring the upper part of the string between the studs of the levers. Adjust the tuning hammer, or harp key, on to the wrest-pin. Wind the latter round to the right till the string becomes taut. If restringing throughout, do not draw up any one string to its proper pitch until the others have been put on and made fairly tight. When the instrument is up to pitch, the tension on the entire frame is very great.

It is not advisable, therefore, to impose a sudden strain on any one part of the neck. The stress should be increased gradually and equally.

**The Fifth Octave.** Having strung the bottom C (red), D, E, F (blue), G, A, B, C (red), D and E, and left them slack, the fifth octave receives attention. The material here is of gut. Later, when ordering strings the student will be able to indicate the exact gauge best suited to his hand. If the string is insufficiently stout, it will jar unpleasantly when played. It must not be too thick or the touch will be difficult. Ladies, as a rule, prefer thinner strings than men, who are able to get a richer tone from a material furnishing more resistance. After unrolling a gut string, hold it to the light, and see that the texture is clear and that it is not lumpy. If flecked or perished, it is useless to put it on. In this octave the lowest string is F (blue). Then come three white strings (G, A, and B), C (red), D, and E. For the fifth octave the best quality of string costs 1s. each.

In the fourth octave there are seven gut strings of smaller gauge than in the preceding set. Of best quality, they cost 10d. each. As before, the lowest string is blue; this is followed by three white, one red, and two white. For the third octave another set of seven, still smaller in gauge, must be adjusted. If superfine, these cost 8d. each.

Continuing higher up on a full-sized harp, there are two more sets to adjust—those of the second and first octave, the latter being the shortest and of the smallest gauge. The respective cost of these is 6d. and 4d. each. Thus, a complete set of five octaves of gut strings, if bought separately, comes to 23s. If purchased together, they may be had for £1. According to the size of the harp, a complete set of wire bass strings costs either 16s. or £1.

**Measurement of Octaves.** In a musical sense octaves are reckoned not from the blue, but from the red strings—from C to B inclusive—although the gauges are calculated from F upwards to E inclusive. If, instead of strings we had pipes—as in the church organ—to obtain the sound of the bottom C in the double-action harp 16 ft. of tubing would be necessary. As the harp is not 16 ft. high, what the string lacks in length is made up in weight. That is the object of having the core of gut overspun with wire. In the same way the C above the lowest B should be 8 ft. in length, or half the length of its octave below. But still there is no room in the harp for this, so the C, D, and E continue to be overspun. The blue F string of very stout gut is the thickest without

metal covering. Above, the next red string represents the 4-ft. pipe in an organ. This 4-ft. octave is also called the *little octave*, because in print the notes are designated by letters of small type, whereas to represent the *great octave* below they are typed in capitals. The octave C above the "little" represents the 2-ft. pipe in an organ. It is also known as the "one stroke" octave, because this section of the compass is represented by a single stroke, or accent, after each letter. Proceeding to the three red strings above, we have respectively the 1-ft., 6-in., and 3-in. pipes of an organ, these being denoted in print by two, three, or four strokes after the letters. Therefore, the vibrating lengths of the top strings of the harp are very short. If it were not for the sympathetic vibrations given out by the longest strings below, these high strings would be scarcely audible. Through the sounding-board, however, their tone is amplified by their longer neighbours, and if the treble strings are good, they have a beautiful silvery effect.

**Tuning.** Before the beginner succeeds in tuning the harp with facility it will take considerable practice. His best plan at first is to have recourse to the keyboard of a piano or harmonium. It may be somewhat bewildering to the eye to find that there are seven flats in the signature of the natural key of the double-action harp, because it is tuned in C $\flat$ . Test the piano by a tuning fork. If it is fairly up to pitch, tune the red string in the centre of the harp representing the 1-ft. octave, or the note C (third space, treble clef) to the B $\sharp$  on the piano, for B $\sharp$  is synonymous with C $\flat$ . But the scale of C $\flat$  has seven flats, whereas the scale of B has only five sharps, so it is easier for the beginner to think of the latter rather than the former. Therefore, for the moment, forget all about the C $\flat$ , and tune the third red string below to the octave B or the note under the first ledger line. Then get a fifth above the bottom note, F $\sharp$ , on the first white string over the blue. Try these three notes together—B, F $\sharp$ , and B on the piano.

Sound the first red string again, and tune the blue string a fifth below it to the E (first line, treble clef) on the piano. Prove together the three notes—two red and one blue—represented on the piano by B, E, and B. Next take the two white strings above the blue and the red. Tune them respectively in fifths to F $\sharp$  and C $\sharp$  on the piano, although on the harp these are really G and D strings. Having done this, tune the octave below the D to C $\sharp$  on the piano. Prove the three white strings, D, G, D, by the C $\sharp$ , F $\sharp$ , and C $\sharp$  on the keyboard. Taking the lowest string, get the A above it (second white this side of the blue), and tune it to G $\sharp$  on the piano. Prove the three, D, A, D, by the C $\sharp$ , G $\sharp$ , and C $\sharp$  on the piano. Taking the middle string of these, tune the E string a fifth above it to the D $\sharp$  (with the G $\sharp$ ) on the piano. From this last E string tune the octave E string below, to the D $\flat$  on the piano. Prove this with the middle A string, or G $\sharp$  on the keyboard. From the lowest of these three strings tune the white

D string—next below the pitch C (first line, treble clef)—together to the notes D $\sharp$  and A $\sharp$  on the piano, proving with the octave string above. By this means the scale between the 2-ft. and 1-ft. C's on the harp has been laid, and all the strings, from the red C up to the second E above, have been drawn up to their proper pitch. Thus, the first greatest strain has been placed on the centre of the neck of the instrument, which, like the keystone of an arch, is that part best able to bear it.

**Octaves.** Having laid the scale, tune the strings above and below in ascending and descending octaves. Begin with the middle blue string (F on the harp). Tune the corresponding blue string above it to agree with the note E (first line, treble clef, and E on fourth space above) on the piano. Tune the three white strings next above respectively to the F $\sharp$ , G $\sharp$ , and A $\sharp$  on the piano. The red strings (C's on the harp) will then be reached. Tune these to the octave B's on the piano. Continue the operation, checking each string by the piano notes until all the top strings have been tuned. Then take the lower notes. Begin with the first white string below the red. Tune this to A $\sharp$  on the piano, with its octave below. Follow on with the next white string, tuning it to G $\sharp$ . The bass clef on the harp usually begins with the first blue string below pitch C. Tune this blue string (F on the harp) to the E on the piano (second ledger-line above the staff) and the E below (third space, bass clef). Follow with the two white strings (tuned to D $\sharp$  and C $\flat$ ), the two red strings (tuned to B on the piano), and so on down the scale.

As soon as the beginner gets accustomed to, and remembers, the various sounds required, he will be able to dispense with the aid of the keyboard. Great harp-players have their different methods of tuning. The late Mr. Oberthür was of opinion that "to tune well and correctly cannot be learnt by rules, as this depends principally upon a correct and musical ear." Yet that master taught many pupils how to tune their instruments by showing them rather than telling them the way. When dealing with so subtle and elusive a force as musical sound, it is easier to convince by demonstration than to explain by word alone. Briefly, however, it may be said that, when desirous of making a brilliant effect, some harpists have a knack of tuning the strings as they ascend a shade sharp; and, in order to get greater depth and fullness of tone towards the bass, the long strings are intentionally left a trifle flat in the extreme octave. This, the purist may argue, is not correct tuning. Nevertheless, it is more than justified when it improves an otherwise dull instrument.

**Position of the Player.** Adjust the music-stool in height so as to bring the chin of the performer level with the neck of the harp when the instrument is drawn back, and turn out the feet to give them easy access to any of the pedals. Draw the harp towards the right shoulder, and let it rest against the right knee.

Generally speaking, those notes written in the treble clef are played by the right hand, and

those in the bass clef by the left hand. The little finger is not used in harp playing. Place the thumb, first, second, and third fingers of the right hand respectively on the F (blue string, first space), E (first line), D, and C (red). Keep the thumb erect, and bend the other fingers gracefully towards the palm of the hand. The knuckles must be kept up. Curve the joints, and avoid bringing the palm towards the player; it is the back of the hand, rather, which should face him. Do not rest the wrist on the soundboard, but when playing in the middle octave keep it elevated. In ascending to the shorter strings, however, this wrist support is allowable. Freedom of finger action must be aimed at, and the carriage of the hand should be light in quickly ascending arpeggios or scales. Too much attention cannot be paid to getting the correct position of the hand. This is not easy at first, owing to the way in which, except in the bass, the fingers must be compressed. The idea is not to pick at the strings with the nails, but to strike with the fleshy tips.

**Right Hand Exercise.** With the third finger of the right hand strike the middle C (fourth red string from the player's body). Bend the finger elastically. Do not move the wrist or arm, the motion should only affect the finger-joint. In the same manner strike the D (above the red C) with the second finger, the E with the first finger. Then proceed to the blue string F. To sound this with the thumb in an upright position, bend the digit slightly at the thumb-joint. Avoid motion of the wrist or arm. Remember, whenever a string has been struck, that the thumb must return at once to its perpendicular attitude. Repeat this exercise (with the third, second, first finger and thumb) slowly. Try to get the sounds equal in clearness, softly at first. When the hand gets accustomed to the strings, use more and more force, and increase the speed.

Adjusting the fingers in advance is an important matter in harp playing; it prevents unnecessary motions of the hand. The student must cultivate the habit of placing the fingers, before they are needed, softly on the string or strings about to be struck. Therefore, before sounding the blue string with the thumb, prepare the third finger on C, the red string below, so that the exercise may continue equally. In like manner, before the C is struck, get the second finger into position for sounding D.

Although the notation on paper in an ascending scale goes from left to right, and has to be played on the harp from right to left, towards the player, the beginner will soon accustom himself to correct transposition of the necessary movements.

**Left Hand Exercise.** The harp player has several advantages over the pianist. If the hands are spread out before one, it will be observed that the right thumb points to the left and the left thumb to the right. This means that, in a parallel passage on the keyboard for both

hands, while one hand begins with the thumb, the other begins with the little finger, and so on, numerically reversing the order of each digit. Now, place the palms of the hand together towards each other, as in the attitude of prayer, instead of placing them away from each other. The left hand is thus the exact counterpart of the right.

**Fingering.** On the harp, therefore, the fingering of the two hands in parallel passages, ascending or descending, is uniform, instead of being dissimilar, as on the piano. Repeat, therefore, with identical manipulation, but an octave lower, the exercise for the right hand just given. Place the third, second, and first fingers and thumb of the left hand respectively on the red string below that struck by the third finger of the right hand, and the B, E, and F above. Be careful to place the fingers in the middle of the length of the strings. Keep the thumb up. As before, the motions should be from the fingers. Avoid moving the wrist or arm. This will be more difficult to do at first with the left hand. Absence of support from the body of the instrument, which the right arm has, makes the task seem almost impossible at first, but steady determination to do the right thing will presently cause the hand to obey the wishes of the mind. At first, softly and slowly, strike the four notes in succession from the C to the F, increasing the speed and strength gradually. Do not continue the exercise when fatigued; rest for a while, and begin again later. When this study can be played clearly by each hand separately, try it with both together. Considering that the fingers of the hand each possess a different strength, the tendency is for their movements to lack steadiness. This uncertainty the beginner must strive to overcome. In the absence of a master, the best way to do this is to practise with a metronome, and make each sound with absolute regularity, increasing the speed of the exercise gradually.

**Inverting the Order.** Now reverse the progression of the notes. After ascending from C to F as before, descend to the C. Be careful to anticipate each sound by placing the finger needed for the next string upon the latter before its time comes to strike. Do not be in a hurry; speed will come later. Try the same exercise with the left hand, keeping the elbow well up. Bad habits, which are easily contracted, usually arise from over enthusiasm when beginning to learn, and continuing practice when tired. The result is rigidity instead of elasticity of movement. The one thing in harp playing which the student must resolve to avoid is stiffness as opposed to gracefulness.

This is a difficult fault to remedy, so let the student, in following the beaten track alone, beware of the ruts; and, however easy progress may seem, avoid practising for too long a time at first.

# THE "WAVERLEY" NOVELS

A Short Study of Sir Walter Scott and his Works, being  
the Third Part of our Course in English Prose Fiction

By J. A. HAMMERTON

THERE is a tendency among some latter-day critics to belittle the great figures of our literary history. It is a simple way of attracting attention to oneself: to quibble about Shakespeare, to grow querulous with Scott, to sneer at Dickens. To write of our literary heroes with anything of the old enthusiasm, to avow oneself their thrall, is regarded, in certain quarters, as evidence of a commonplace mind. Well, these little pettifogging critics have their day and cease to be, and their scribblings vanish as utterly as the grass that withereth. The heroes remain; nay, they grow greater, for their roots are deep struck into the fruitful soil of their country's life. Let us be nowise afraid of displaying too much enthusiasm in their praise, though we may be denied the gift of eloquence. If we are told that nobody reads Scott nowadays, he's out of date, let us forthwith see that we re-read him. Happier still will be our condition if we have any or all of his novels with which to make first acquaintance. One of the noblest heritages of the Britisher is that glorious library of romance, the "Waverley Novels." And soon or late most of us awaken to this knowledge; he who fails to apply it remains a poor man in midst of plenty. As Hazlitt said so happily, Scott's works, "taken together are almost like a new edition of human nature." Lord Rosebery considers that more people read Henty than Scott. This would be deplorable if true, but it is deplorable that so excellent a bookman as Lord Rosebery should entertain the thought. When Scott has so fallen into neglect that any common novel spinner is more widely read than he, we may well despair of public taste. But we are enthusiastic enough to believe that Scott is as much read to-day as ever; that he will be read as long as Edinburgh rock stands in the midst of an English-speaking town, even though the romantic castle around whose grey old walls he played in boyish games may have crumbled into dust. Scott is as firmly rooted in our national life as Edinburgh rock in Scotland's soil.

**The Waverley Novels.** Age cannot wither nor custom stale the infinite charm of SIR WALTER SCOTT (b. 1771; d. 1832). There are some writers who appeal to the instincts of men and women only at particular periods of their lives. The Wizard of the North claims the love and homage if not of the seven ages, of five of them at the least. He is easily first of the great writers of English fiction. He is the father of the historical romance. If from the wide range of English literature two champions only had to be selected as representative, the selection would surely fall on William Shakespeare and Walter Scott. From every point of view we

could spare these least of all of our great imaginative writers. If the student, the greater part of whose time is devoted to other than literary studies, should ask us to name the minimum of books essential to culture in its highest sense, we should say without hesitation: Read and re-read and make companions of the Bible, the works of Shakespeare, and the works of Scott.

But we take it that the majority of the readers of this section of the SELF-EDUCATOR are students first of English literature, its byways as well as its highways, and that therefore they seek guidance to more than the best books themselves; that, in fact, as we have before suggested, they look for the man behind the book. In the case of Scott they have a noble quest. "This was a man!" And we must be brought face to face with him before we can fully appreciate the splendid work that is but part of him. Therefore, we would have the young student spend his days and nights for a while with Lockhart's "Life"—the second best biography in our language—and the equally moving pages of the now famous "Journal." Such time would be well and profitably spent. If this advice be taken as counsel of perfection, well, there is an admirable monograph by Mr. Andrew Lang, in the "Literary Lives" series. This brief biography, or rather appreciation, breathes that spirit of critical hero-worship which none but the best of men can inspire. Moreover, with the pen of the gifted writer, displayed to its fullest advantage, Mr. Lang brings before us the man of whom he writes—a man whose life was a greater romance than, perhaps, any that has been written out of the fulness of his own or any other man's imagination.

**Scott's Aims as a Novelist.** The career of Sir Walter Scott illustrates, as Professor Raleigh points out, the renewal and decision of the old battle between verse and prose for the prerogative possession of romantic themes. Scott "took the bread out of the mouths of the novelists" by his metrical romances, "The Lay of the Last Minstrel" (1805), "Marmion" (1808), "The Lady of the Lake" (1810); then, turning to prose, he proved that the historical and romantic interests need not be imperilled by the admixture of qualities that are known only to prose. "In his works the novel proper and the romance, which had long been coquetting with each other, were at last wedded." Scott's genius was stirred by several causes—among them being the French Revolution, the Napoleonic wars, Percy's "Reliques of Ancient English Poetry," the songs of Burns, the ballads of Bürger, and the early poems of Goethe. Nor must the example of Fielding be discounted.

But the Irish novels of Maria Edgeworth first inspired in him the thought which found such eloquent expression in that vast treasure-house of literature which we know as the "Waverley" novels. We commend to the student as steps preliminary to the reading of these novels (1) a consultation of the "General Preface," written by Scott in 1829, which will be found in the first volume of all good editions; and (2) the "Epistle" introductory to "The Fortunes of Nigel," written in 1822. Readers of the "Life" will appreciate the spur of necessity that drove Scott, who was never a laggard, to become a toiler by night and by day, in sickness and in health; no man of honour, genius, or spirit such as his was, ever made the love of gain less the purpose of his labours. He explains, in the "Epistle" to which we refer, that he was quite aware of the aims of Fielding, Smollett, Le Sage and others, as writers of novels, but he goes on to remark that it was enough for him could he "write with sense and spirit a few scenes, unlaboured and loosely put together, but which had sufficient interest in them to amuse in one corner the pain of body; in another to relieve anxiety of mind; in a third place to un wrinkle a brow bent with the furrows of daily toil; in another to fill the place of bad thoughts, or to suggest better; in yet another to induce the idler to study the history of his country; in all, save where the perusal interrupted the discharge of serious duties, to furnish harmless amusement."

**History in Scott's Novels.** Others before Scott, as both Professor Masson and Mr. Lang remind us, had attempted the historical novel, "but wholly without his knowledge of history and of the actual way of living and thinking in various periods of the past." He it was who "first made the dry bones of history live." The casual reader needs to be reminded of the stores of varied and accurate learning which were garnered in Scott's capacious mind. This man was a student from his youth upwards. It is important also to secure at the outset of our study of his historical works a knowledge of his methods of dealing with history. Scott's plan was never to make a famous character of history the central personage of his tale. He never coped with the records of actual events. But he achieved effects denied to some of the most painstaking and letter-faithful among historians proper.

In all that Scott wrote, we breathe the free air of the mountain heights. He has made

goodness interesting without beauty, without overmastering tragedy, without wallowing naked in the pathetic, without passion.

**Scott's Manliness.** His chivalry is a reproach to all who seek to achieve fame by meaner methods. "Scott and Homer had a sense of reverence of human things: they did not lack the imagination necessary for the portrayal of the evil and terrible, but they did not seek success in that popular region. Scott was no prude, but he held the young in reverence, knowing that among them he must have many readers." The "Waverley" novels "are not the work of any Peeping Tom who studies woman in her dressing-room, and tries to spy or smell out the secrets of the eternally feminine." For the reader with any true feeling there can be few moments in modern literature more memorable than that in which Diana Vernon (in "Rob Roy"), stooping down from her Highland

pony, bids her lover farewell for ever. Yet Carlyle, all of whose references to Scott are not ungenerous, has placed on record the remark that Scott "fashions his characters from the skin inwards, never getting near the heart of them." Never was word more lightly spoken by man of intellectual weight. "Never," asks Mr. Lang, "never near the broken, stoical heart of Saunders Mucklebackit (in 'The Antiquary'); of the fallen Bradwardine (in 'Waverley'), happy in unsullied honour; never near the heart of the maddened Peter Peebles (in 'Redgauntlet'); never near the flawless Christian heart of Bessy Maclure (in 'Old Mortality'); or the heart of dauntless remorse of Nanty Ewart (in 'Redgauntlet'); or the heart

of sacrificed love in Diana Vernon (Scott's early love); or the stout heart of Dalgetty (in the 'Legend of Montrose'), in the dungeon of Inveraray; or the secret soul of Mary Stuart (in 'The Abbot'), revealed when she is reminded of Sebastian's bridal masque, and the deed of Kirk o' Field?"

**Scott's Leading Characters.** "The glory of Scott's work," says Mr. Lang, "is, of course, not merely his wealth of incident, and his natural gift of story telling, but his crowd of characters, from his princes, such as James VI., an immortal picture, Louis XI., Elizabeth, Mary, Charles II., in flight or in such prosperity as he loved, to his Highland chiefs, his ploughmen, his lairds, Bucklaw, and old Redgauntlet the persecutor; his copper captains in Alsatia, his bailies, his Covenanting preachers, his Claverhouse, his serving men, his Andrew Fairservice,

## LITERATURE

his yeomen, his Dandie Dinmont, with the Dinmont family and terriers, his wild women—Meg Merrilies and Madge Wildfire"—Norna might be included; "his smugglers, his lawyers, from Pleydell to the elder Fairford, and even his bores, who, like Miss Austen's bores, are certainly too much with us—who can number the throng of such characters, all living and delightful? The novels are *réçus*: the author has, in imagination, lived closely and long with his people, whether of his own day or of the past, before he laid brush to canvas to execute their portraits. It is in this capacity, as the creator of a vast throng of living people of every grade, and every variety of nature, humour, and temperament, that Scott, among British writers, is least remote from Shakespeare."

**How to Read Scott's Novels.** When the student, either from Lockhart's pages or those of Mr. Lang, has made himself conversant with the story of Scott's life, he will find in the novels much of the inner history of that life reflected. Having ourselves in our earlier years read the "Waverley" novels in the order (or want of order) suggested by the fancy of their titles, we later turned to Lockhart, and then took up the novels in the order in which they were published. The result was a revelation; and we seriously commend the course indicated to every literary aspirant as well as to the general reader. The "Waverley" novels make excellent reading for the family circle; we mean for that reading aloud, with discussion afterwards, which is an aid not only to the better understanding of the author, but to many other things that are equally desirable. Such a method of reading will bring out into strong relief the wholesome philosophy of the author. Scott's novels, it must be remembered, do not depend for their popularity finally upon their plots. Taking time to arrange a story was a sore point with Scott. "I have," he has told us, "repeatedly laid down my future work to scale, divided it into volumes and chapters, and endeavoured to construct a story which I meant should evolve itself gradually and strikingly, maintain suspense and stimulate curiosity, and which, finally, should terminate in a striking catastrophe. But I think there is a demon who seats himself on the feather of my pen when I begin to write, and leads it astray from the purpose. Characters expand under my hand; incidents are multiplied; the story lingers while the materials increase; my regular mansion turns out a Gothic anomaly, and the work is closed long before I have attained the point I proposed." Scott himself is his own keenest critic. He tells us further: "When I light on such a character as Bailie Jarvie, or Dalgetty, my imagination brightens and my conception becomes clearer at every step which I take in his company, although it leads me many a weary mile away from the regular road, and forces me to leap hedge and ditch to get back into the route again."

**Scott's Literary Style.** It has to be remembered, also, that much which was new when Scott wrote, has now become hackneyed,

and as we do not base our claim for Scott on the excellence of his plots, so we do not fall back upon his style, of which the best that can be said is that it is a free and easy medium wherewith he brings more valuable things than style alone before us. R. L. Stevenson, who loved Scott and understood him as well as any critic that ever wrote of him, said many severe things about his literary style, and nowhere more aptly than in "A Gossip on Romance," which is printed in "Memoirs and Portraits," and should be read by the student. Scott was to Stevenson, as to every reasonable student of him, so gigantic that he could be made the subject of the severest criticism in details without in the least seeming to detract from the mighty mass of his merits.

**Chronology of the "Waverley" Novels.** By taking up the novels in the order in which they were published rather than as fancy or other reasons may dictate, the student will be able to discern the workings of the author's mind when dealing successively with special phases of character and particular situations in human life. As to the introductions and notes, these are not essential to the story in hand, and may be reserved for consideration till each story has been read. With the remark that the authorship of the "Waverley" novels was for long a secret, in which rich and poor, from the throne downwards, interested themselves, it may be useful if we give a list of these works, with the dates of their publication, and an indication of the period with which they deal.

| Year of Publication. | Title.                                | Period. |
|----------------------|---------------------------------------|---------|
| 1814                 | "Waverley; or 'Tis Sixty Years Since" | 1745    |
| 1815                 | "Guy Mannering"                       | 1760    |
| 1816                 | "The Antiquary"                       | 1798    |
| 1816                 | "Old Mortality"                       | 1679    |
| 1816                 | "The Black Dwarf" *                   | 1708    |
| 1817                 | "Rob Roy"                             | 1715    |
| 1818                 | "The Heart of Midlothian"             | 1736    |
| 1819                 | "A Legend of Montrose"                | 1644    |
| 1819                 | "The Bride of Lammermoor"             | 1700    |
| 1819                 | "Ivanhoe"                             | 1194    |
| 1820                 | "The Monastery"                       | 1559    |
| 1820                 | "The Abbot"                           | 1570    |
| 1821                 | "Kenilworth"                          | 1575    |
| 1821                 | "The Pirate"                          | 1700    |
| 1822                 | "The Fortunes of Nigel"               | 1620    |
| 1823                 | "Quentin Durward"                     | 1470    |
| 1823                 | "Feveril of the Peak"                 | 1660    |
| 1823                 | "St. Ronan's Well"                    | 1804    |
| 1824                 | "Redgauntlet"                         | 1770    |
| 1825                 | "The Betrothed"                       | 1187    |
| 1825                 | "The Talisman"                        | 1193    |
| 1826                 | "Woodstock"                           | 1651    |
| 1827                 | "The Surgeon's Daughter"              | 1765    |
| 1827                 | "The Two Drovers" †                   | 1765    |
| 1827                 | "The Highland Widow" †                | 1755    |
| 1828                 | "My Aunt Margaret's Mirror" †         | 1700    |
| 1828                 | "The Tapestry Chamber" †              | 1780    |
| 1828                 | "The Laird's Jock" †                  | 1600    |
| 1828                 | "The Fair Maid of Perth"              | 1402    |
| 1829                 | "Anne of Geierstein"                  | 1474    |
| 1827                 | "Tales of a Grandfather"              | 1707    |
| 1830                 | "Count Robert of Paris" *             | 1788    |
| 1831                 | "Castle Dangerous"                    | 1090    |
| 1831                 | "Tales of My Landlord."               | 1307    |

† "Chronicles of the Canongate."

**The Origin of "Waverley."** A glance at the foregoing list will serve to show that with few exceptions Scott, with all his love of the Gothic, preferred to deal in his novels with periods not far remote from his own time; but he did for Scottish romance what Cervantes did for Spanish chivalry. Fourteen years before the appearance of "Waverley" Scott attempted the vein associated with the romantic tales of Mrs. Radcliffe and Horace Walpole. The first seven chapters of "Waverley" were written in 1805, and then, on the advice of a friend, put away, forgotten, and only recalled by the success of Miss Edgeworth and the task of completing "Queenhoo Hall," an unfinished romance by James Strutt. The lost MS. was discovered when Scott was in quest of fishing tackle, and the story was finished in four weeks. These facts are of particular interest as showing that Scott did not take to the writing of prose fiction because Byron had beaten him in poetry. Thenceforward, for sixteen years, says Professor Herford, in his "Age of Wordsworth," "the wonderful series of the 'Scotch novels,' as they were called, issued from the Ballantynes' press without a pause; and for the last ten, at least, their appearance was watched for as eagerly in Paris and Weimar as in London. The poems had thrown the British world into a passing excitement; the novels enlarged the intellectual horizon of all Europe, created in half-a-dozen nations the novel of national life, and opened a new epoch in the study of history." Two facts stand out clearly on a careful review of these novels: one is that the characters are types, the second is the wonderful fidelity of the descriptions of natural scenery. If the novels be classified it will be found that two-thirds of them are historical; and it is worth noting, as examples of the way in which Scott's pen "ran away with him," how "The Heart of Midlothian" grew into one of the most humanly interesting of his books from what at first was a desire to write a novel around the Porteous Riots, and how, in "A Legend of Montrose," history is again secondary to the creation of the immortal Dugald Dalgetty.

**Scott as a National Asset.** All literature is a national asset—the theme is one which the young student would find wonderfully suggestive for inquiry—and it is difficult to exaggerate what the British people in general, and the Scots in particular, owe to the author of the "Waverley" novels.

"Scott," as Professor Masson has said, "is greatest in his Scotticism. It is as a painter of Scottish life, an interpreter of Scottish beliefs and Scottish feelings, a narrator of Scottish history, that he attains to the height of his genius. He has Scotticised European literature. He has interested the world in the little land. It had been heard of before; it had given the world some reason to be interested in it before;

with, at no time, more than a million and a half souls in it, it had spoken and acted with some emphasis in relation to the bigger nations around it. But, since Scott, the Thistle, till then a roadside weed, has had a great promotion in universal botany, and blooms less prickly than of yore, but the identical Thistle still, in all the gardens of the world. All round the globe the little land is famous; tourists flock to it to admire its scenery, while they shoot its game; and afar off, when the kilted regiments do British work, and the pibroch shrills them to the work they do, ask whence they come, the answer is 'From the land of Scott.'"

The late James McNeil Whistler was asked, "What is the Future of English art?" and is said to have answered, "Phil May." It would be no extravagance if one were asked "What is English romance?" to answer "Walter Scott." Yes; and French romance also, for his influence in France was profound; but for Scott there might have been no Dumas. He is ours to read with delight, to learn from, to love, to use as the golden key admitting to one of the fairest kingdoms of earth, if indeed it be not the veritable fairy land—the Kingdom of Romance.

**Bibliographical Note.** There are so many good and cheap editions of the "Waverley" novels that it is almost invidious to recommend one more than another. The "Centenary" edition, published by Messrs. A. and C. Black, is one of the best. Messrs. Macmillan publish a delightful illustrated pocket edition in 25 volumes, on India paper, edited, with Introductory Essays and Notes, by Mr. Andrew Lang; 2s. net per volume. Another India paper pocket edition, also in 25 vols., at 2s. net per volume, is issued by Messrs. Nelson. Messrs. Dent publish an edition—the "Temple" edition—edited by Mr. Clement K. Shorter, in 48 vols. at 1s. 6d. net per vol. Mr. Andrew Lang's "Sir Walter Scott" (Hodder and Stoughton, 3s. 6d.) gives much that is vital in small compass. Mr. Le Grys Norgate's "Sir Walter Scott" (Methuen, 7s. 6d.) is a painstaking piece of work though lacking fire. Mr. R. H. Hutton's "Scott," in the "English Men of Letters" Series (Macmillan, 1s. 6d), and the "Life" by Prof. Saintsbury should not be overlooked. The best edition of Lockhart's "Life" is the second in 10 vols. (1838, Black, 30s.); Messrs. Black add the work to their "Centenary" issue in 2 vols. and publish an abridged edition at 6s. Messrs. Hutchinson also publish an abridged edition at 1s. The "Journal" was published in one and two-volume form in 1890 (Edinburgh, David Douglas). Nassau W. Senior, in his "Essays on Fiction" (Longmans), deals at some length with Scott as a writer of historical romance, and in Sir Richard Jebb's "Introduction to Homer" (Maclehose) there is a striking parallel between Homer and Scott.

### AUXILIARY VERBS

There are three auxiliary verbs in Spanish, viz., *haber*, to have ; *ser* and *estar*, two forms of the verb to be.

Pronouns are rarely expressed with the verb, unless similarity of termination in the first and third persons makes it necessary to avoid ambiguity.

#### Conjugation of *Haber*, To have

|                        |                          |
|------------------------|--------------------------|
|                        | GERUND, OR               |
| INFINITIVE             | PRESENT PARTICIPLE       |
| <i>haber</i> , to have | <i>habiendo</i> , having |

|                     |
|---------------------|
| PAST PARTICIPLE     |
| <i>habido</i> , had |

#### INDICATIVE MOOD

##### Present

*he*, I have  
*has*, thou hast  
*ha*, he has  
*hemos*, we have  
*habeis*, you have  
*han*, they have

##### Past Definite

*hube*, I had  
*hubiste*, thou hadst  
*hubo*, he had  
*hubimos*, we had  
*hubisteis*, you had  
*hubieron*, they had

##### Imperfect

*había*, I had  
*habías*, thou hadst  
*había*, he had  
*habíamos*, we had  
*habíais*, you had  
*habían*, they had

##### Future

*habré*, I shall have  
*habrás*, thou wilt have  
*habrá*, he will have  
*habremos*, we shall have  
*habréis*, you will have  
*habrán*, they will have

#### CONDITIONAL MOOD

*habría*, I should have  
*habrías*, thou wouldst have  
*habría*, he would have  
*habríamos*, we should have  
*habríais*, you would have  
*habrían*, they would have

#### SUBJUNCTIVE MOOD

##### Present

*haya*, I may have  
*hayas*, thou mayst have  
*haya*, he may have  
*hayámos*, we may have  
*hayais*, you may have  
*hayán*, they may have

##### Imperfect

*hubiera* or *hubiese*, I might have  
*hubieras* or *hubieses*, thou mightst have  
*hubiera* or *hubiese*, he might have  
*hubiéramos* or *hubiésemos*, we might have  
*hubierais* or *hubiéseis*, you might have  
*hubieran* or *hubiesen*, they might have

##### Future

*hubiere*, when I shall have  
*hubieres*, when thou wilt have  
*hubiere*, when he will have  
*hubiéremos*, when we shall have  
*hubiéreis*, when you will have  
*hubieren*, when they will have

1. To have, as an independent verb signifying to possess, is expressed by *tener*, to have, hold, or possess. Example: *Tengo un caballo*, I have a horse.

2. *Haber* is also an impersonal verb forming its own compound tenses by the addition of the past participle *habido*. The present of the indicative is *hay*, there is, there are. Examples: *Hay pan*, There is bread ; *Hubiese habido guerra*, There might have been war.

3. The simple tenses of the verb *haber* with the preposition *de* and the infinitive of another verb signify must, have to, etc. Examples: *Todos los hombres han de morir*, All men must die ; *Hemos de salir hoy*, We have to go out to-day.

4. *Tener* is also used as an auxiliary in this manner, with the addition of *que* before the infinitive instead of *de*. Examples: *Tengo que salir*, I have to go out ; *Tienen que trabajar*, They have to work.

### Ser and Estar

The use of *ser* and *estar*, the two forms of the verb to be, must be carefully distinguished :

1. *Ser* is used to express an inherent and permanent quality. Example: *Soy un Inglés*, I am an Englishman.

2. *Estar* expresses a passing condition. Example: *Estoy cansada*, I am tired.

3. *Ser* is always used with the past participle of a verb, to form the passive voice.

4. *Estar* is used with the present participle to express the progressive form of an active verb. Example: *Ser amado*, to be loved ; *Estar durmiendo*, to be sleeping.

#### Conjugation of *Estar*, To be

|                      |                        |
|----------------------|------------------------|
| INFINITIVE           | GERUND                 |
| <i>estar</i> , to be | <i>estando</i> , being |

#### PAST PARTICIPLE

*estado*, been

#### INDICATIVE MOOD

##### Present

*estoy*, I am  
*estás*, thou art  
*está*, he is  
*estamos*, we are  
*estáis*, you are  
*están*, they are

##### Past Definite

*estuve*, I was  
*estuviste*, thou wast  
*estuvo*, he was  
*estuvimos*, we were  
*estuvisteis*, you were  
*estuvieron*, they were

##### Imperfect

*estaba*, I was  
*estabas*, thou wast  
*estaba*, he was  
*estábamos*, we were  
*estábais*, you were  
*estaban*, they were

##### Future

*estaré*, I shall be  
*estarás*, thou wilt be  
*estará*, he will be  
*estaremos*, we shall be  
*estaréis*, you will be  
*estarán*, they will be

CONDITIONAL MOOD

*estaría*, I should be  
*estarias*, thou wouldst be  
*estaría*, he would be  
*estaríamos*, we should be  
*estaríais*, you would be  
*estarian*, they would be

IMPERATIVE MOOD

*esté*, be (thou) *estemos*, let us be  
*esté*, let him be *estad*, be (you)

SUBJUNCTIVE MOOD

*Present.*

*esté*, I may be  
*estés*, thou mayest be  
*esté*, he may be  
*estemos*, we may be  
*estéis*, you may be  
*estén*, they may be

*Imperfect*

*estuviera* or *estuviese*, I might be  
*estuvieras* or *estuvieses*, thou mightst be  
*estuviera* or *estuviese*, he might be  
*estuviéramos* or *estuviésemos*, we might be  
*estuviérais* or *estuviéreis*, you might be  
*estuvieran* or *estuviesen*, they might be

*Future*

*estuviere*, when I shall be  
*estuvieres*, when thou wilt be  
*estuviere*, when he will be  
*estuviéremos*, when we shall be  
*estuviéreis*, when you will be  
*estuvieren*, when they will be

The compound tenses of *estar* are formed with the verb *haber* and the past participle *estado*: *haber estado*, to have been; *he estado*, I have been, etc.

Vocabulary

Ambition  
 To be ambitious  
 To have had ambition

 . . . . .

5. Había salido con mi perro, estando el colegial en casa. 6. Habré de tener un caballo, habreis de comprar una mula. 7. Hemos de heredar mucho dinero. 8. Hemos muerto al ladrón.

# PROSE EXTRACT VIII.

From "An Essay on Shakespearo," by Juan Valera.

Few authors have taken more from others than Shakespearo. Everything which he thought beautiful, sublime, amusing, agreeable, or witty, he took without scruple where he found it. A wise man has said that in literature robbery is not only excusable, but even glorious when it is followed by murder. Shakespearo was well aware of this, and he has not failed to murder all those he robbed, for not one of them would be remembered if he had not robbed them. They are all dead—but Shakespearo lives, and the characters which those authors created or evoked to a vague and shadowy life in a dim uncertain twilight have been brought by Shakespearo into the radiant noonday light of immortal glory, and to a life firmer, clearer, and more real than that of all the heroes of history.

The worth of Shakespearo must have been great to have accomplished this, but his good fortune has been greater still. Who doubts, however, that fortune is the most potent element of worth?

Faust, Marguerite, and Mephistopheles, Werther and Charlotte in German, and Don Quixote, Sancho, Dulcinea, and Don Juan Tenorio, the Spanish are the only characters in European literature so well known that their fame and shining

Pocos autores han tomado más de los otros que Shakespearo. Todo lo que le parecía bello sublime, divertido, agradable, gracioso, lo tomaba sin escrúpulo donde lo hallaba. Ha dicho un discreto, que en la literatura, no solo se disculpa sino que se glorifica el robo cuando le sigue el asesinato. Shakespearo sabía esta máxima, y no dejó de asasinar á cuantos robó, de los autores robados nadie se acordaría si no hubieran sido robados. Todos murieron—mas Shakespearo vive, y los personajes que aquellos autores crearon ó evocaron á una vida vaga y como de sombra, y á una luz indecisa crepuscular é incierta, han sido traídos por Shakespearo á la radiante y meridiana luz de la gloria inmortal y á una vida más firme, más clara, más real que la de todos los héroes de la historia.

Grande ha sido el valor de Shakespearo para conseguir esto: pero ha sido mayor su fortuna. ¿Quién duda sin embargo, de que la fortuna es el más poderoso elemento del valor?

Fausto, Margarita, y Mefistófele, y Werther y Carlota, en la literatura alemana, y solo D. Quijote, Sancho, Dulcinea, y D. Juan Tenorio, en la española, son las personas que por la notoriedad la fama, y el fulgor glorioso se pueden com-

glory can be compared to the characters of Shakespearo.

But is this due to the fact that there is no character but Don Juan, in the dramas of Lope, Tirso, Calderon, Moreto, Alarcon, and Rojas, or in the whole of our great Spanish dramatic literature, as full of the breath of life and predestination to immortality as the Shakespearoan heroes? It is true that in all our great dramatic literature there are no other characters that live like these. Does the fault lie with our poets or with fortune?

Shakespearo wrote for a nation beginning to be great, about to extend its empire, improve its individual and racial civilisation, and diffuse and make it felt throughout all the regions of the earth. Writing for the people, he was inspired by, and full of, the thoughts and feelings of the people, and his mind and works are big with the future; they contain the germ of the spirit of England to-day.

Our dramatists also wrote for the people, and were full of the feelings of the people—but of a people on the point of death, a people whose individual racial civilisation was about to disappear, and in whom the spirit of those days was not to be the spirit of to-day. Thus it is that their heroes speak a language which even Spaniards hardly understand, and express feelings and ideas which Spaniards no longer share. How, then, can strangers understand them when Spaniards understand them no more?

pararse á los personajes de Shakespearo en las literaturas europeas.

¿Pero depende esto de que en los dramas de Lope, Tirso, Calderon, Moreto, Alarcon y Rojas de que en todo nuestro gran teatro español no haya más personajes que D. Juan con tanto aliento de vida, con tanto predestinación para la inmortalidad, como los héroes Shakespearianos? La verdad es que no hay en nuestro gran teatro español otros personajes que vivan como aquellos. ¿Fué mengua de nuestros poetas ó, de la fortuna?

Shakespearo escribió para un pueblo que empezaba á ser grande, que iba á extender su imperio, á mejorar su civilización castiza y propia á difundirla y á hacerla valer por todas las regiones del mundo. Como escribió para el pueblo, escribió inspirado y lleno de los pensamientos y sentimientos del pueblo, y su mente y sus obras están henchidas de lo porvenir; contienen en germen todo el espíritu de Inglaterra en el día.

Nuestros dramáticos escribieron también para el pueblo y llenos de los sentimientos del pueblo—pero de un pueblo que moría, de un pueblo cuya civilización castiza y propia iba á desaparecer, y cuyo espíritu de entonces no había de ser el espíritu de ahora. De aquí es que aquellos héroes hablen una lengua que apenas entienden ya los españoles, y expresen sentimientos é ideas de que los españoles mismos ya no participan. ¿Cómo, pues han de entenderlos los extranjeros, cuando los españoles no los entienden ya?

Juan Valera (1830-1905), one of the most distinguished men of letters of this century. He was a poet, critic, novelist, and diplomatist, and the author of "Pepita Jimenez," probably the best known of modern Spanish novels. The essay from which our extract is taken was written as a preface to a translation of Shakespeare's works by D. Jaime Clark.

Juan Valera (1830-1905), uno de los hombres mas distinguidos de este siglo. Fué poeta, crítico, novelista, diplomático, y autor de "Pepita Jimenez," probablemente la novela mejor conocida de las novelas modernas españolas. El ensayo del cual hemos tomado nuestro extracto fué escrito como prefacio de una traducción de las obras de Shakespeare por D. Jaime Clark.

# KEY TO EXERCISE IX. (1).

1. Esa mujer vino cual un ángel de Dios.
2. ¿Quién cantó? Nadie cantó.
3. Alguien vino esta mañana.
4. Alguno me ha dicho.
5. Algo se ha de decir.
6. Nada me dijo.
7. Ninguno conoce el criminal.

          *domandino*,      they ask

Perfect

|  |  |
|--|--|
| (che) abbia domandato, (that) I have asked |  |
| „ abbia domandato, „ thou have asked       |  |
| „ abbia domandato, „ he have asked         |  |
| „ abbiamo domandato, „ we have asked       |  |
| „ abbiate domandato, „ you have asked      |  |
| „ abbiano domandato, „ they have asked     |  |

Imperfect

|  |  |
|--|--|
| (che, se) domandassi, (that, if) I asked |  |
| „ domandassi, „ thou asked               |  |
| „ domandasse, „ he asked                 |  |
| „ domandassimo, „ we asked               |  |
| „ domandaste, „ you asked                |  |
| „ domandassero, „ they asked             |  |

Pluperfect

|  |  |
|--|--|
| (che, se) avessi domandato, (that, if) I had asked |  |
| avessi domandato, thou had asked                   |  |
| avesse domandato, he had asked                     |  |
| avessimo domandato, we had asked                   |  |
| aveste domandato, you had asked                    |  |
| avessero domandato, they had asked                 |  |

CONDITIONAL MOOD

Present

|                                |
|--------------------------------|
| domanderei, I should ask       |
| domanderesti, thou wouldst ask |
| domanderebbe, he would ask     |
| domanderemmo, we should ask    |
| domandereste, you would ask    |
| domanderebbero, they would ask |

Perfect

|  |
|--|
| avrei domandato, I should have asked       |
| avresti domandato, thou wouldst have asked |
| avrebbe domandato, he would have asked     |
| avremmo domandato, we should have asked    |
| avreste domandato, you would have asked    |
| avrebbero domandato, they would have asked |

INFINITIVE MOOD

|   |
|---|
| Present : domandare, to ask             |
| Perfect : aver domandato, to have asked |

Gerund

|  |
|--|
| Present : domandando, asking             |
| Perfect : avendo domandato, having asked |

Participle

|  |
|--|
| Present : domandante, -i, asking       |
| Perfect : domandato, -a, -i, -e, asked |

EXERCISE XIX.

|                                       |
|---------------------------------------|
| amare (ahmähreh), to love             |
| insegnare (eensehnee-ähreh), to teach |
| imparare (eempahrahreh), to learn     |
| lavare (lah-vähreh), to wash          |
| cantare (cahn-tähreh), to sing        |
| perdonare (pehr-donähreh), to forgive |
| bruciare (broo-chee-ähreh), to burn   |
| lavorare (lahvorähreh), to work       |
| pensare (pehn-sähreh), to think       |
| studiare (stodee-ähreh), to study     |
| tagliare (tah-lee-ähreh), to cut      |
| ballare (bahllähreh), to dance        |
| contare (contähreh), to count         |
| accettare (ahcheh-ttähreh), to accept |
| mentire (mahncähreh), to fail         |
| sperare (spehrähreh), to hope         |
| cambiare (cahmbee-ähreh), to change   |
| mangiare (mahndgee-ähreh), to eat     |
| fumare (foomähreh), to smoke          |
| ingannare (eengahnähreh), to deceive  |

They spoke. Did they speak? Dost thou love? Did you learn? I did not wash. We shall pay. Let us forget. Do you sing? Do not ask. If you bought. If we bought. They would forgive. To burn. Assured. When I entered. He entered. If I entered. Working. Having copied. We shall have paid. We shall begin. We thought. They learned. If I had studied. I think they have accepted. Let us pray. We should advise. We would have refused. I will not fail. Have they not sent? I thought they had sent.

Remarks on the First Conjugation.

1. Verbs ending in *-care, -gare, -scare* preserve the guttural sound throughout the conjugation; therefore an *h* must be added to *c, g, sc* before the terminations beginning with *i* or *e*. [See Observations on the Plural of Nouns, page 2485.] Examples: *Cercare*, to look for, *cerciamo*, we look for, *cerceremo*, we shall look for; *pregare*, to pray, *pregiamo*, we pray, *pregnerò*, I shall pray; *pescare*, to fish, *pesciamo*, we fish, *pesceremo*, we shall fish.

2. Verbs ending in *-ciare, -giare, -sciare* preserve the palatal sound throughout the conjugation, therefore an *i* must be added to *c, g, sc* before the terminations not beginning with *i* or *e*. Examples: *cominciare*, to begin; *cominciano*, they begin; *cominciò*, he began; but *cominceremo*, we shall begin, *cominciamo*, we begin (and not *cominc-i-eremo, cominc-i-iamo*); *mangiare*, to eat; *mangiamo*, they eat; *mangiamo*, we ate; but *mangeremo*, we shall eat; *mangiamo*, we eat (and not *mang-i-eremo, mang-i-iamo*); *lasciare*, to let; *lasciano*, they let; *lasciò*, he let; but *lascieremo*, we shall let; *lasciamo*, we let (and not *lasc-i-eremo, lasc-i-iamo*).

3. Verbs ending in *-chiare* and *-gliare* drop the *i* before terminations beginning with an *i*. Example: *pigliare*, to take; *pigliamo*, we take; (not *pigli-iamo*); *apparecchiare*, to prepare; *apparechiamo*, we prepare (not *apparechi-iamo*).

4. Verbs ending in *-iare* (with the *i* accented in some of the forms of the conjugation) retain the *i* before the terminations *-i, -ino*. Example: *obliare*, to forget; *oblii*, thou forgettest; *obliino*, that they may forget; but *obliamo*, we forget (and not *obli-iamo*); *inviare*, to send; *invii*, thou sendest; *inviiino*, that they may send; but *inviamo*, we send (not *inv-i-iamo*).

NOTE. In the forms *obliamo, inviamo, etc.*, the *i* must be pronounced very distinctly: *oblèe-ähmo, eenvee-ähmo*.

EXERCISE XX.

|  |
|--|
| viaggiare (veeahdgee-ähreh), to travel   |
| confidare (confeedähreh), to entrust     |
| provare (provähreh), to try              |
| aspettare (ahspehttäähreh), to wait      |
| passaggiare (pahssehdg-eeähreh), to walk |
| guastare (guhstähreh), to spoil          |
| mostrare (mosträhreh), to show           |
| nevicare (nehveeähreh), to snow          |
| ritornare (reetornähreh), to return      |
| ascoltare (ahscollähreh), to listen      |
| sgridare (sgreedähreh), to scold         |
| suonare (soo-onähreh), to ring, to play  |

*indovinare* (eendovee-nàhreh), to guess  
*bisbigliare* (bees-bee-lee-àhreh), to whisper  
*incontrare* (een-contràhreh), to meet  
*toccare* (toccàh-reh), to touch  
*è necessario* (eh nehchessàh-reo), it is necessary  
*credo* (crèhdo), I think, I believe  
*avvenire* (ahvveh-neè-reh), future  
*consiglio* (conseeè-leeo), advise  
*sano e salvo* (sàhno eh sàhloo), safely.

1. Noi studiamo l'Italiano. 2. Quest'anno abbiamo viaggiato tutto l'inverno e viaggeremo ancora questo autunno. 3. È necessario che voi pensiate al vostro avvenire. 4. Se avessimo ascoltato i vostri consigli avremmo ancora tutto il nostro danaro. 5. Io mangiai molto poco.

ma voi non mangiaste addirittura niente. 6. Incontreremo i nostri amici a Parigi, e ritorneremo insieme a Londra. 7. Speriamo che tutti arrivino sani e salvi. 8. Sbagliando s'impara (one learns). 9. Se avessimo lavorato di più avremmo già completato il nostro lavoro; ora chi sa (who knows) se l'avremo completato quando il padrone lo (it) domanderà. 10. Arrivate in tempo l'altra sera? 11. Credo che presto nevicherà. 12. Guardate, ma non toccate. 13. Non dimentichiamo di aiutare i poverelli. 14. Io avevo già copiato la lettera quando egli entrò. 15. Portate questa lettera al suo indirizzo, per piacere. 16. Quando essi arrivarono trovarono la porta chiusa.

### VERBS

#### Conditional Mood

1. The CONDITIONAL expresses state or action as depending on some condition, and is connected with an "if" clause in past time:

*Les soldats feraient bien leur devoir s'ils étaient bien commandés*, The soldiers would do their duty properly if they were properly commanded.

2. It is also used as a future in past time:

*Il m'a dit hier qu'il viendrait aujourd'hui*, He told me yesterday that he would come to-day.

3. The conditional must never be used after *si*, if: I would write to you if I should have need of you, *Je vous écrirais si j'avais besoin de vous*.

4. In English the past is frequently used instead of the conditional after "when," "as soon as," etc.; in French the conditional must always be used:

I told him I should speak to you about it as soon as I saw you, *Je lui ai dit que je vous en parlerais dès que je vous verrais*.

5. The pluperfect subjunctive is used as a second form of the conditional; and when that is the case it may be preceded by *si*, if:

*Il n'eût pas publié son ouvrage, s'il n'eût pas cru qu'il pût être utile*, He would not have published his work, if he had not believed that it might be useful.

In this sentence the first pluperfect subjunctive may be replaced by the past conditional; but the second, being preceded by *si*, can be replaced only by the indicative:

*Il n'aurait pas publié son ouvrage, s'il n'avait pas cru qu'il pût être utile*.

6. If "would" and "should" are "notional verbs" in English, the conditional does not suffice to express them. An independent verb, usually *devoir*, must then be used:

If you have not yet done it, you should do it without further delay, *Si vous ne l'avez pas encore fait, vous devriez le faire sans plus tarder*.

#### Subjunctive Mood

1. The SUBJUNCTIVE is used in subordinate sentences, as its name implies. It usually follows main clauses expressive of a wish, desire or command, prohibition, pleasure, regret

By Louis A. Barbé, B.A.

or necessity, or containing a negative or an interrogative verb:

*Je souhaite que vous réussissiez*, I wish you may succeed;

*Je désire qu'il vienne*, I desire him to come;

*J'ordonne que vous lui obéissiez*, I order you to obey him;

*Nous sommes ravis que vous ayez réussi*, We are delighted that you have succeeded;

*Je ne savais pas que vous fussiez amis*, I did not know you were friends;

*Croyez-vous qu'il vienne?* Do you think he will come?

2. The SUBJUNCTIVE is also required after certain conjunctions, such as, *afin que*, in order that; *quoique*, although; *de crainte que*, for fear lest; *pourvu que*, provided that;

*Ce livre est toujours sur le bureau, afin qu'on puisse le consulter*, That book is always on the desk, so that it may be consulted;

*Quoiqu'il soit pauvre, il est heureux*, Although he is poor, he is happy.

3. The present subjunctive follows a present or future in the main clause.

4. The imperfect follows any of the past tenses and also the conditional:

*Il faut que nous écrivions*, It is necessary that we should write;

*Il faudra que nous écrivions*, It will be necessary for us to write;

*Il fallait que nous écrivissions*, It was necessary that we should write;

*Il faudrait que nous écrivissions*, It would be necessary that we should write.

#### Infinitive Mood

1. The INFINITIVE is used without any intervening preposition after certain verbs, of which the most common are: *aimer mieux*, and *préférer*, to prefer; *croire*, to believe; *désirer* and *vouloir*, to wish; *devoir*, to have to (ought, must); *falloir*, to be necessary; *faire*, to make, to cause to; *laisser*, to let; *oser*, to dare; *pouvoir*, to be able; *regarder* and *voir*, to look at, to see; *savoir*, to know how to; *entendre* and *écouter*, to hear, to listen to:

*J'aime mieux ne rien dire*, I prefer to say nothing;

*Il croit bien faire*, He thinks he is doing right ;  
*Il veut parler*, He wishes to speak ;  
*Il faut obéir aux lois*, It is necessary to obey the laws ;

*Nous avons fait bâtir une maison*, We have got a house built ;

*Il a laissé tomber sa canne*, He has let his walking-stick fall ;

*Je le vois venir*, I see him coming ;

*Il sait lire et écrire*, He can read and write.

2. In English verbs of motion are frequently connected by "and" to another verb in the same tense. In French the second verb is put in the infinitive :

I shall go and see him, *J'irai le voir*.

3. Of the verbs that require *à* before an infinitive, the following are of frequent occurrence :

*Aimer*, to like to ; *apprendre*, to learn, to teach ; *commencer*, to begin ; *consentir*, to consent ; *enseigner*, to teach ; *renoncer*, to give up ; *réussir*, to succeed :

*Il aime à jouer*, He likes to play ;

• *Elle apprend à tricoter*, She is learning to knit ;  
*Cet enfant commence à parler*, That child is beginning to talk ;

*Nous avons réussi à le convaincre*, We have succeeded in convincing him ;

*Consentez-vous à le recevoir?* Do you consent to receive him ?

4. Of the verbs that require *de* before an infinitive, the following are the most common :

*Achever* to complete, finish ; *finir*, to finish ; *cesser*, to cease ; *commander*, to command ; *conseiller*, to advise ; *craindre*, to fear ; *défendre*, to forbid ; *empêcher*, to prevent ; *prier*, to beg ; *refuser*, to refuse ; *regretter*, to regret :

*Il cessa de parler*, He ceased speaking ;

*Il commanda aux soldats de faire feu*, He commanded the soldiers to fire ; *Je vous conseille de ne pas y aller*, I advise you not to go there ; *Craignez-vous de ne pas réussir?* Do you fear not to succeed ? *Il nous a défendu de jouer*, He has forbidden us to play ; *Empêchez-le d'entrer*, Prevent his coming in ; *Il m'a prié de lui écrire*, He begged me to write to him ; *Je regrette de ne pas l'avoir vu*, I regret not having seen him.

5. Impersonal expressions made up of *être* and an adjective require *de* before the infinitive :

*Il est impossible de l'arrêter*, It is impossible to stop him ; *Il est facile de s'y méprendre*, It is easy to make a mistake about it.

6. When not occurring in impersonal expressions, adjectives are usually followed by *à* :

*C'est facile à comprendre*, That is easy to understand ; *Il est difficile à contenter*, He is difficult to please.

7. An infinitive is usually preceded by *de* when it is used as the complement of a noun :

*Le désir de plaire*, The wish to please ; *Il est l'heure de dîner*, It is the dinner hour ; *Laissez-moi le temps de ranger mes affaires*, Leave me time to put my things in order.

### Present Participle

THE PRESENT PARTICIPLE always ends in *ant*, and is invariable. It expresses an action,

and differs in this from the verbal adjective which also ends in *ant*, but expresses a quality, and agrees in gender and number with its noun :

*Voyez-vous la rosée dégouttant des feuilles?*  
Do you see the dew dropping from the leaves ?  
*Voyez-vous ces feuilles dégouttantes de rosée?*  
Do you see those leaves dripping with dew ?

### Past Participle

THE PAST PARTICIPLE of regular verbs ends in *é* in the first conjugation, *onné* ; in *i* in the second, *ini* ; and in *u* in the third and fourth, *reçu*, *venu*.

1. The past participle, when not accompanied by *être* or *avoir*, plays the part of an adjective, and agrees in gender and number with its noun :

*Les méchants ont bien de la peine à demeurer unis*, The wicked have great difficulty in remaining united.

2. When the past participle is accompanied by *être*, it agrees with the subject of the verb :

*La vertu obscure est souvent méprisée*, Obscure virtue is often despised.

3. When a past participle is accompanied by *avoir*—that is to say, in all the compound tenses of active verbs—it agrees, not with the subject of the verb, but with the direct object, provided that object precedes the verb :

*Les meilleures harangues sont celles que le cœur a dictées*, The best harangues are those which the heart has dictated.

In this sentence *dictées* agrees with *que*, which is the direct object and precedes the verb. But there is no agreement in *Le cœur a dicté les meilleures harangues*, The heart has dictated the best harangues, because the object, *les meilleures harangues* comes after the verb.

### KEY TO EXERCISE XXIV.

1. Les ours grimpent sur les arbres.
2. Le soleil brille pour tout le monde.
3. La terre ne refuse rien à ceux qui la cultivent.
4. Les chemins de fer ont contribué au progrès du commerce.
5. S'il vous prête son livre n'oubliez pas de l'en remercier.
6. Il y a plus d'une heure que nous travaillons.
7. Celui qui n'a pas cultivé ne récoltera pas.
8. Vous regretterez de ne pas lui avoir parlé.
9. On m'a empêché d'entrer.
10. Vos parents désirent que vous travailliciez assidûment.
11. Il y avait deux heures que je l'attendais quand on m'a apporté sa lettre.
12. Le siège de Troie dura dix ans.
13. Si je l'osais je lui demanderais de me prêter vingt francs.
14. Il m'a dit qu'il m'expliquerait cette règle.
15. Quand nous eûmes achevé notre travail, nous allâmes jouer.
16. Je lui ai dit hier que je viendrais lui parler aujourd'hui.
17. Il ne nous rencontre jamais sans nous emprunter de l'argent.
18. Je ne lui aurais rien donné s'il n'avait pas eu l'air si malheureux.

19. Croyez-vous que votre père rentre avant midi ?

20. Je souhaite qu'il vous donne ce que vous lui avez demandé.

21. Le dictionnaire est sur la table ; consultez-le.

22. Priez-le d'entrer.

23. Demandez à vos amis ce qu'ils pensent de vous.

24. Votre frère parle-t-il français aussi bien que vous ?

25. Il est difficile de triompher du préjugé.

26. Votre ami oserait-il leur parler s'il les rencontrait ?

## GERMAN

Continued from  
page 3216

By P. G. Konody and Dr. Osten

### LXII. Auxiliary Verbs of Mood.

There are six auxiliary verbs of mood in German: können, to be able; dürfen, to be allowed; mögen, to like; wollen, to be willing; sollen, to be to (I ought); müssen, to be obliged. These are irregular verbs [see LXI.], and do not denote independent actions, but are generally used to modify the actions expressed by other verbs. The latter (when employed with an auxiliary verb of mood) stand in the infinitive (dependent infinitive).

1. The auxiliary verbs of mood and the verbs lassen, to let; heißen, to bid, lehren\*, to teach lernen\*, to learn; sehen, to see; helfen, to help machen, to make, to do; brauchen, to need form the past participle in two ways: (a) used independently with the weak suffix -t and the prefix ge-; and (b) in connection with a dependent infinitive [see LXII.] of the strong form (suffix -en), which has the same sound as the infinitive. Thus, können forms the weak past participle ge-könn-t, and the strong past participle könn-en: Ich kann (independent verb) meine Aufgabe, I know my lesson, and Ich kann (auxiliary verb of mood with dependent infinitive) meine Aufgabe her-sagen, I am able [I know] to say my lesson; Ich habe meine Aufgabe ge-sen-t, I have known my lesson, and Ich habe meine Aufgabe her-sagen könn-en, I have been able to say my lesson.

2. If the dependent infinitive is omitted, as being obvious, the past participle of the auxiliary verb of mood stands alone and is used in its weak form: Haben Sie Ihre Aufgabe her-sagen könn-en? Have you been able to say your lesson? Ich habe nicht ge-sen-t, I have not been able. In a similar way are used: Ich habe es ihm ge-hei-ßen (weak past participle), I have bid him [do] it, and Ich habe es ihm tun ge-hei-ßen (strong past participle) [also ge-hei-ßen]; Ich habe etwas ge-mach-t, I have made something, and Ich habe von mir reden ge-mach-t [also ge-mach-t], I have made [people] talk of me.

3. Compounds of the verbs mentioned in LXII., 1, only take the weak, and never the strong form of the past participle. Examples: be-dürfen, to be in need of, be-durft; ver-mögen, to be able, ver-mocht; ge-bräuchen, to use, ge-bräucht; auf-helfen, to help, to succour, auf-ge-helfen. These past participles are of course formed according to the rules which govern the verbs with separable and inseparable prefixes.

\* The strong forms, „lehren“, „lernen“, are but very rarely used in modern German, the weak forms, „gelehrt“, „gelernt“, being generally employed.

4. The use of the auxiliary verbs of mood differs greatly in the two languages, and the correct employment of them in German can only be acquired by practical experience. The general uses of these auxiliary verbs of mood will be dealt with subsequently.

**LXIII. Passive Voice of Verbs.** Only transitive verbs [see XLI. b] admit of the passive voice in all tenses. The active voice: Der Vater liebt das Kind, The father loves the child, is changed into the passive by changing the subject of the sentence: Das Kind wird vom Vater geliebt, The child is [gets] loved by the father. In the first case the father is the subject, in the second the child. With intransitive verbs the passive voice can generally only be formed with the aid of the impersonal es, it, which then is the subject: Die Schmitzer mähten, The mowers mowed; and passive: Es wurde von den Schmitzern gemäht.

1. Many intransitive verbs, especially in sentences which indicate measure and answer to the questions how much? how long? how far? admit no passive voice: Der Kranke lag vier Wochen (im Bett), The patient lay four weeks [was in bed four weeks], cannot be put into the passive voice. Der Mann zählt 80 Jahre, The man counts 80 years [is 80 years of age]; but never: es wurden vom Manne 80 Jahre gezählt.

2. Transitive verbs which in certain connections denote the passive state even in the active voice cannot easily be brought into the passive voice: Er verlor die Geduld, He lost [the] patience, does not admit the passive: Die Geduld wurde von ihm verloren.

3. Where custom has formed a kind of idiomatic unity (compound) of the verb and object, the passive is not employed, though it is grammatically correct: Der Gedanke schlug Wurzel in ihm, The idea took root in him, but passive (not in use): Wurzel wurde in ihm vom Gedanken geschlagen.

4. As a rule no passive voice is formed by the verbs sein, to be; werden, to become; bleiben, to remain, stay, stop; scheinen, to shine, seem, appear; heißen, to name, call, bid; dürfen, to seem, appear; dürfen, to be permitted; and by the impersonal (whether intransitive or transitive), the reflective and the reciprocal verbs.

**LXIV. Formation of Tenses in the Passive Voice.** All tenses in the passive voice are formed by combinations of the past participle of the verb with tenses of the auxiliary verb werden, to become, to grow. Thus the passive voice of the verb fangen, to catch, is formed by

the past participle of fangen: gefangen and the auxiliary verb werden:

*Present Indicative:* 1. ich werde, 2. du wirst, 3. er wird; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen.

„ *Subjunctive:* 1. ich werde, 2. du werdest, 3. er werde; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen.

*Imperfect Indicative:* 1. ich würd-e, 2. du -est, 3. er -e; *pl.* 1. wir -en, 2. ihr -et, 3. sie -en gefangen.

„ *Subjunctive:* 1. ich würd-e, 2. du -est, 3. er -e; *pl.* 1. wir -en, 2. ihr -et, 3. sie -en gefangen.

*Perfect Indicative:* 1. ich bin, 2. du bist, 3. er ist; *pl.* 1. wir sind, 2. ihr seid, 3. sie sind gefangen worden.

„ *Subjunctive:* 1. ich sei, 2. du seiest, 3. er sei; *pl.* 1. wir seien, 2. ihr seiet, 3. sie seien gefangen worden.

*Pluperfect Indicative:* 1. ich war, 2. du warst, 3. er war; *pl.* 1. wir waren, 2. ihr wart, 3. sie waren gefangen worden.

„ *Subjunctive:* 1. ich wäre, 2. du wärest, 3. er wäre; *pl.* 1. wir wären, 2. ihr wäret, 3. sie wären gefangen worden.

I. *Future Indicative:* 1. ich werde, 2. du wirst, 3. er wird; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen werden.

„ *Subjunctive:* 1. ich werde, 2. du werdest, 3. er werde; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen werden.

II. *Future Indicative:* 1. ich werde, 2. du wirst, 3. er wird; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen werden sein.

„ *Subjunctive:* 1. ich werde, 2. du werdest, 3. er werde; *pl.* 1. wir werden, 2. ihr werdet, 3. sie werden gefangen werden sein.

I. *Conditional:* 1. ich würde, 2. du würdest, 3. er würde; *pl.* 1. wir würden, 2. ihr würdet, 3. sie würden gefangen werden.

II. *Conditional:* 1. ich würde, 2. du würdest, 3. er würde; *pl.* 1. wir würden, 2. ihr würdet, 3. sie würden gefangen werden sein.

*Infinitive Present:* gefangen werden.

„ *Past:* gefangen werden sein.

In the perfect and pluperfect the final werden can be dropped where a continuance of the action prevails and has to be denoted: Ich bin gefangen! I am caught! (in the very moment of this action); or ich war gefangen (werden)! I was caught, which lends more vigour and fluency to the statement.

#### EXAMINATION PAPER XVII.

- How many past participles are formed by the auxiliary verbs of mood and several other verbs, and which form of the verb is one of them sounded like?
- Which prefix and suffix are taken by these verbs in the past participle, when used independently, and which when in connection with a dependent infinitive of another verb?
- What form of past participle is taken by the compounds of these verbs?
- Which verbs admit of the passive voice?
- How is it possible to form the passive voice of some intransitive verbs?

6. Which verbs do not admit of the passive voice?

7. What are the constituents of the verb in its passive voice, and how are the tenses formed?

8. Which auxiliary verb of tense is employed in the passive voice?

**EXERCISE 1.** Insert the correct past participle of the auxiliary verbs of mood:

Ich habe nicht . . . . . Er hat nicht . . . . .  
I have not been willing. He has not been able.

Er hat nicht kommen . . . . . Sie hat nicht  
He has not been able to come. She has not been

kommen . . . . . Wir haben nicht spielen . . . . .  
willing to come. We have not been allowed to play.

Er hat mich holen . . . . . Sie hat  
He has had [let] me fetched. She has

es mich wissen . . . . . Er hat fliehen . . . . .  
let me know it. He has been obliged to escape.

Ich habe die Kinder spielen . . . . .

I have let the children play.

Die Bauern haben ihn hören . . . . .  
The peasants were obliged to hear him.

Er hat nicht zu kommen . . . . .

Ho has not needed to come.

(There was no need for him to come).

Der Vater hat es mich tun . . . . . (or . . . . .).  
The father has bid me to do it.

Ich habe ihn kommen . . . . . Wir haben sie singen . . . . .  
I have seen him come. We have heard her sing.

Du hättest es tun . . . . . Ich habe ihm  
You ought to have done it. I have helped

aufstehen . . . . . Die Geschichte hat sie weinen . . . . .  
him to get up. The story has made her weep.

**EXERCISE 2.** (a) Change the following sentences into the passive voice:

Das Kind trägt den Korb. Das Publikum  
The child carries the basket. The public [audience]

hört die Musik. Der Vater liest die Zeitung.  
hears the music. The father reads the paper.

Der Vater las die Zeitung. Die Mutter hat  
The father read the paper. The mother has

die Eier gekocht. Das Kind hatte den Hund gequält.  
boiled the eggs. The child had teased the dog.

(b) Change the following present tenses of the passive voice into the imperfect, perfect, and first future:

Der Feind wird besiegt. Du wirst geliebt.  
The enemy is being beaten. Thou art loved.

Er wird eingeladen. Wir werden geachtet. Ihr werdet  
He is laughed at. We are esteemed. You are

betrogen. Sie werden aus der Schule ausgeschlossen.  
being cheated. They get expelled from the school.

(c) Change the above sentences into the passive pluperfect and second future.

#### KEY TO EXERCISE IN EXAMINATION PAPER XVI. (PAGE 3215)

**EXERCISE 1.** Der Müller mahlt das Korn. Der  
Künstler hat das Bild gemalt. Hast du den Kaffee

gemahlen? Wenn ich nur mit euch gehen könnte!  
Er muß heute gehen. Das Haus brannte. Der Vater

brachte die Geschenke für die Kinder. Warum wußtet Ihr  
nichts? Ich durfte nicht spielen. Sie dachte nicht

dar an. Die Köchin salzte das Fleisch. Das Fleisch  
war nicht gesalzen. Er sandte ihr Blumen. Was hat

er ihr gesandt?

**NOTE.** The Key to Exercise 2 will be given in Part 24.

# CARPET WEAVINGS

Designing Brussels, Wilton, and other Heavy Carpets. Special Features of Patent Axminster, Tapestry, and Scotch Carpets

Group 28  
TEXTILES

23

Continued from  
page 3157

By W. S. MURPHY

**S**IMPLE and obvious as the fact is, carpet designers frequently forget that a carpet is intended to cover a floor. Trees, shrubs, landscapes, bouquets of flowers bound with ribbons, figures of wild and ferocious animals, human faces or figures, are among the unsuitable designs which have frequently been employed in the making of carpets. Carpets should not be made to serve as pictures; domestic conditions forbid it. The carpets which have been generally accepted by the best and most cultured taste are masses of subdued and rich colours formed by small and regular figures on a geometrical basis. We do not, however, altogether condemn the attempt to bring the beauty of Nature's children, the flowers and the grasses, into the home. But the designer must always be on his guard to avoid incongruity and egregious bad taste. If made frankly conventional, and without any attempt at realism, we believe that good use might be made of natural objects of beauty and charm.

## Brussels Carpets.

We speak technically of three-frame, four-frame, five-frame, or six-frame Brussels, and by that is meant the number of different layers of threads composing the carpet. According to ancient practice, the number of frames told the number of different colours and the number of layers of thread employed in forming the fabric. We have altered the practice a good deal, but it will serve our purpose quite well to study the older practice. In the breadth of a Brussels carpet there are 260 threads. Suppose we have five-frame—that makes five sets of 260 reels containing the requisite length of thread. Each frame holds thread of a different colour. Our pattern paper has upon it 260 squares in its breadth, and the depth may be according to pattern [143]. We may determine to repeat our pattern as many times as we please in the breadth, but if the sides of the carpet are to be symmetrical, the pattern must be a multiple of the total number of threads. In other words, we must complete every repeat of the pattern within the breadth of the carpet. Every square represents a point of colour, and every point of colour is made by a loop of thread. The section marked a

is named the *gamnot*, and gives the key of the design.

**Structure of Brussels Carpet.** We must understand somewhat the structure of the carpet. Let us take a single-thread section of a four-frame Brussels carpet [144]. First, we have the linen warp, and on top of this we draw our four threads of worsted from the frames. At the fore end of the loom are the looping wires. The one thread which has to appear on the surface is drawn up and looped on the wire, while all the others lie under. The linen weft flies across with a binding pick; the linen warp reverses the shed, and the weft makes another pick. A loop has formed. At the next movement another frame thread may be called up to the surface, to form a loop of a different colour, and the same movements are gone through. This is repeated the whole length of the web. Looking now at the structure, we see that the four threads form the body of the carpet, the one forming the loop always resting on the four others. By this means a massive and elastic fabric is formed, and a variety of colour

143 DESIGN OF BRUSSELS CARPET

and pattern is obtained.

Such are the conditions upon which the designing of Brussels carpets is based. It is for the young designer to study the best models, and to work out in practice the patterns he thinks most suitable and desirable.

**Wilton Carpets.** This class of carpet is simply the Brussels carpet with the loops cut to form the velvet pile. Usually, the ends of the looping wires are formed into a small knife, and as they are withdrawn, cut the loops. Very often the loops on the Wilton are larger than those on the Brussels. One thing the designer of Wilton carpets must remember is that the cut pile threads incline all in one direction, and the design of each woven strip should be adjusted to the fact.

**Patent Axminster Carpets.** The name of this carpet has been derived from the first attempt to produce the Persian tufted carpet in this country. Persian carpets are formed by knotting the tufts or threads of wool into the linen warp by hand, and securing them with a strong pick of weft. The building together of so large a fabric tuft by tuft involves long

## TEXTILES

labour, but the results are splendid, both in wearing quality and artistic value. In the production of a commodity which consumes a large amount of labour-time, the manufacturers of this country with difficulty compete against the cheap labour available in India and Asia generally. Begun at Axminster, the little Devonshire town, about 1755, by French settlers, the industry grew to some importance; but increased facilities of communication with the East, and the stress of competition caused thereby, affected the prosperity of the trade to such an extent that it could not stand alone. The seat of manufacture removed to Wilton, where a large trade in Brussels carpets was being carried on. This wise expedient of associating the superb tufted carpet with other and more popular forms of the fabric has been widely adopted, and an industry of considerable value and interest has been saved to the nation. Carpet manufacturers in Kidderminster, Bridgnorth, Pontefract, and other places make it a department of their factories, for the supply of what, we hope, is a growing market.

The Patent Axminster design [145] is first worked out in preparation for the chenille loom, on which the strips of connected threads forming the carpet pile are woven. We then cut the design into strips [146], and thus get the rows to be combined. As many as a dozen different shuttles may be used in succession, or at intervals, on the chenille loom. Every strip of chenille fringe forms a line across the carpet, and the threads in it must be varied according to the pattern. The "cloth" [147] comes off the loom and is cut into threads, the sections of which are shown [148].

From these simple facts it is evident that, both in Axminster and Patent Axminster, the carpet designer is wholly unfettered by considerations of structure. He can vary the colour of every thread as he pleases, and combine them in any manner he thinks most effective. Our design, when coloured, is exactly the picture of the carpet in miniature. With a very little experience of the difference between the flat effect on pointed paper and the soft effect of the carpet pile, we

can perceive at a glance the character of a design. The Persian method of teaching the designing of carpets may be recalled as a final hint. The pupils are shown a design, and instructed in the

position of every thread. As soon as the pupil thinks he knows the pattern, or when the teacher thinks he ought to know it, the

design is taken away, and he is required to reproduce it in every detail. The generalising habit, too common among ourselves, would not do in Persia.

### Tapestry and Velvet-Pile Carpets.

The rise in the standard of living among the working and middle-class people of this country during the nineteenth century created a market for carpets which, while costing less than a Brussels, would present a similar appearance and possess fairly good wearing quality. As if in anticipation of the coming time, carpet manufacturers vied with each other in the production of a cheap and useful carpet of the style desired. Most successful of these

attempts was the *tapestry* carpet which was invented by an Edinburgh manufacturer, Richard Whytock, and upon which a large industry has been built up. In structure this form of carpet closely resembles velvet. First, there is the ground warp; second, the weft—both composed of linen, or perhaps jute. Next, we put in the extra worsted warp, which is to form the pile of the carpet, when it has been made ready. But that waits till we have made the design.

If no pattern were desired, the extra warp could be put in plain; but then the tapestry carpet would be nothing more than a rough imitation of terry velvet. In this case, colour and pattern

do more than add something to the appearance; they take the eye off the rough grain of the fabric. The extra warp is only one thread thick; the substance of the carpet is formed by looping up the warp in the style of all plush fabrics. When the looped pile is high, the warp shows only about one inch in four on the surface of the cloth. Inferior pile, of course, uses a smaller proportion of thread. For the sake of

illustration we shall keep to the higher quality. The pattern is formed by the different colours of the loops; the loops are made on the warp threads; for every point of colour we must

144. SECTION OF BRUSSELS CARPET

145. PATENT AXMINSTER CARPET

146 THE METHOD OF CUTTING DESIGN

147. CHENILLE CLOTH

make a section of the warp four times the length of the said colour. The thread in this case has to be dyed or stained, with different colours, in various sections along its whole length, and

will be if the pinions which control the toothed rim are set to catch certain numbers. On the broad-side of the drum ten or a dozen hanks of white worsted yarn are wound, the yarn in single

#### 148. THREAD OF PATENT AXMINSTER CARPET

every thread in the breadth of the carpet requires to be so coloured. Before considering the means of realising it, let us go on with the method of making the design.

The best results are got by first making a picture of some suitable object, or group of objects. We may venture boldly, for the yarn will combine in any style we please. With good taste as a guide, the prettiest effects imaginable may be produced. Rosebuds peeping out from variegated green foliage, trails of flowers, rich suggestions of heathy moorland, and all the numerous combinations of line, curve, and square, are open to us. Our picture having been made, it is first transferred on to pointed paper [149]. Then if the design harmonises, it is again transferred on to large sheets, the threads of which will make fairly broad slips of paper, and the spots proportionately elongated four times [150].

This set of sheets is cut up, every thread being made into a slip. Each slip of paper is a picture of the length of the thread of warp necessary to complete the design [151]. Seen by itself, it is an unintelligible slip of paper barred with colour. Put all the slips together again, and the design, almost ludicrously elongated, appears [152]. These slips go into the hands of the warp yarn printer.

**Yarn Printing.** This form of printing is special to tapestry carpet manufacture. The printing machine is a tin drum [153], rimmed with an index showing the number of loops contained in yarn wound upon it. Drums are of various sizes, according to the length of the carpet to be woven from the yarns printed upon it. For a large-sized carpet, the drum is over 16 ft. in diameter, and the index numbers on the rim run up to 864. The drum is slung on a frame, and under it two rails cross; on these rails sits a small trough [154] filled with liquid colour, while depending on the sides of the trough hangs a little felt-covered roller half immersed in the colour. Beside the drum hangs a ready-reckoner, or table, which shows the printer what the effect

layer and each hank separate. When this has been done, the printer gathers in a row his little troughs of dye, each one a different colour. He takes the first slip of coloured model paper, and marks off the spaces occupied by one colour and the number of times it appears. The index rim and the clutch are set; the trough of colour, with its roller, is put on the rails. Now lay on the drive.

At the required point the drum stops and the trough runs across its width, the colour roller printing a broad line of dye on the yarn. Again the drum moves round and stops, and the roller makes another line of colour. Another trough with a different colour is put on and the index adjusted. The yarn takes on more bands of dye, it may be broad masses or perhaps only single strokes, according to the design. Again and again the action is repeated, till the whole drum is covered with dyed yarn, banded like a rainbow. One thread of our pattern has been produced. If this pattern is not repeated on the carpet, if the carpet is one pattern only, we have only made one thread of so many webs of carpet, and need to repeat this printing no fewer than 218 times. But it is really all one, in a great factory, whether we are producing one thread for 3,000 yards of carpet or ten threads for 300 yards of the fabric.

Different manufacturers have different ways of working, and it is easy to see that the printing drum may be worked to suit various methods. An instrument so handy and so simple in its working can be utilised in a variety of styles. The principle alone is important, and we have seen its action.

In tapestry carpet yarn printing we have a method of fixing the colours which has peculiar features. When the hanks are taken off the drums, they are laid in latticed troughs and covered over with bran; thus encased, the yarn is put through the steaming stoves, and the colours fixed. Next the yarns are thoroughly washed in flowing water and dried in the hot stoves.

149. DESIGN OF TAPESTRY CARPET

150. SECTION OF ELONGATED DESIGN

151. SINGLE THREAD OF TAPESTRY CARPET

152. TAPESTRY CARPET THREADS SET

Having been reeled on to bobbins, the yarns are ready for the setters.

**Setting.** At one end of a long table a creel of warp bobbins is placed; at the other end is a weaving beam; midway is a movable clamp across the setting table, which can be shifted, fixed, and loosened at will. The setter has a complete pattern of the design, and works to it. From the bobbins the yarn is drawn off, and the threads, with their various bars of colour, are laid on the flat board. We draw the thread up close to the beam and under the lifted clamp. Note the pattern, and draw the one thread and the next, and the next, placing the bars of colour in the range ordered by the pattern. When all the threads are placed, a long, shadowy outline of the pattern is seen in the ranged yarn. Every thread must be exactly adjusted, so that each bar of colour comes into place. This section set satisfactorily, the whole breadth of warp is wound on the beam, and the clamp is fixed. We have made the first section of a tapestry carpet warp. The forming of the whole warp is nothing more than a repetition of this process.

**Kidderminster, or Scotch Carpets.** This form of carpet is merely a kind of double cloth. Here we have two warps and two wefts, with the methods of binding common to all double cloths. As a rule, the warps are worsted, and the wefts are woollen yarns. Woven with coloured yarns, these carpets are made into very fine and elaborate designs, some calling for the use of 16 shuttles carrying wefts of different shades and colours. But no new principle of design is involved; it is a very straightforward process the designing of the Scotch carpet. We encounter no subtle difficulties or special peculiarities. The lack of wearing quality in the soft fabrics induced Morton, of Kilmarnock, to introduce a threefold carpet, and the idea has certainly made carpets that wear well. The centre ply is a plain warp, with figured wefts on both sides. The "three-ply," as it is called, has the added advantage of affording more points of binding for the separate cloths, and making them more durable.

**Mixed Pile Warp.** For many years the pile of nearly all classes of carpet has been worsted yarn. Ground warp and binding weft may be linen, jute, or cotton, and the kind of material used affects very little the character of the design. In most factories the choice of binding warp and weft lies with the manager of the weaving department, or the general manager. On the pile warp alone, the designer is expected

to put forth his skill. Here, for a long time, the carpet designer was happily exempt from the necessity for studying very deeply those problems in textile calculation which are so constantly making demands on the designers of other

textiles. As we all know, however, many of the most beautiful carpets of the East owe their loveliness to the free use of mixed yarns in building up the pile. Silks, filigree, and specially fine wools have been introduced to diversify and beautify the carpet, and these bring very difficult problems to the designer. If, however, the carpet is to maintain its position against the rivalry of competing fabrics, some advance must be made, and this direction seems at once the most effective and the most practicable. The introduction of mixed pile yarns opens up a wide field for the designer. To equip himself for taking part in this advance, the student should pay special attention to the

tables of textile calculations which have been made up by generations of practical men. What the ready reckoner is to the clerk, the tables of calculations are to the textile worker.

**Different Yarns.** With the growing popularity of the carpet, manufacturers have been impelled to spread their efforts over a wide area. Extension has taken place in two opposite directions—towards costliness on the one hand, and towards cheapness on the other. The silk carpet, formerly regarded as either an impossible luxury to all save Eastern potentates or American millionaires, or as a curiosity of ancient workmanship, fit only for the museums, has become commercial and an article of regular trade. At present we import most of our silk carpets from Wurrungal,

Lahore, and other parts of India; but there is no reason why the trade in silk carpets woven in this country should not grow.

Needless to say, the cheap carpet is made of cotton. Though lacking the softness and elasticity of the woollen article, these cotton carpets are wonderfully good, and wear well. The cotton carpet has been objected to because it may be readily set on fire; this is a danger, but it is easily obviated by the manufacturer. Into that province of things we do not propose to enter.

In the ways we have indicated, the sphere of the carpet designer has been greatly enlarged. From being an isolated unit in the textile world, he is being brought into contact with all the other members of his craft. Every designer, in fact, should make himself thoroughly acquainted with the principles of textile design as a whole, and specialise in practice.

# LIFE HISTORIES OF INSECTS

Jointed-limbed Animals. Peripatus. Centipedes and Millipedes. Wingless Insects. Leaf Insects and Grasshoppers. Bugs. Dragon-flies, May-flies, and Caddis-flies.

Group 23  
**NATURAL HISTORY**

24

ZOOLOGY  
continued from  
page 2391

By Professor J. R. AINSWORTH DAVIS

THE great sub-kingdom of JOINTED-LIMBED ANIMALS (*Arthropoda*) includes far more numerous species than any other, and is abundantly represented in both salt and fresh water, on the land, and in the air. It may be conveniently divided into two great groups, Air Breathers (*Tracheata*) and Gill Bearers (*Branchiata*), each split up into several classes, as follow:

**Air Breathers.** (1) PRIMITIVE AIR BREATHERS (*Prototracheata*), (2) CENTIPEDES AND MILLIPEDES (*Myriapoda*), (3) INSECTS (*Insecta*), (4) SCORPIONS AND SPIDERS (*Arachnida*).

**Gill Bearers.** (1) LOBSTERS AND CRABS (*Crustacea*), (2) KING CRABS (*Xiphosura*), (3) EURYPTERIDS (*Eurypterida*), (4) TRILOBITES (*Trilobita*).

In all members of the sub-kingdom the body is divided into a series of rings or segments, some at least of which bear jointed limbs; and there is an external horny covering that serves as a protection. The central nervous system consists of a ring surrounding the gullet and connected below with a cord running along near the under surface of the body. The upper side of the ring is swollen into a more or less distinct brain.

## AIR-BREATHERS

Air-breathing arthropods are typical land animals, among which the insects have acquired wings. The name "Tracheata" is derived from the fact that the breathing organs most commonly present are in the form of delicate tubes (*tracheae*) which branch within the body, and communicate with the exterior by a series of small holes (*stigmata*).

### Primitive Air-breathers

This small group includes but one type, *Peripatus* [412], the species of which have a very wide distribution through the hotter parts of the globe, being represented in South America, the West Indies, South Africa, the Malay region, Australia, and New Zealand. The absence of means of rapid dispersal points to the extreme antiquity of the group, a conclusion which is fully confirmed by a study of its structure.

*Peripatus*, in fact, may almost be described as an arthropod in the making, and though no doubt exists as to how it should be classified, many of its characters ally it to the segmented worms (*Annelids*), a group which gives us some idea of the ancestors from which all the jointed limbed animals have descended. This archaic creature lives in rotten tree-stumps and other dark places, and might almost be mistaken for a caterpillar on cursory examination. The body is not clearly divided into rings, and the

numerous pairs of legs are conical stumps, which are not divided into proper joints. Each of them bears a pair of sharp claws at its tip.

The mouth is on the under side of the head, and is provided with a single pair of jaws, formed by the modification of a pair of legs. The jaws of arthropods in general are not, like those of backboned animals, part of the framework of the head, but modifications of the jointed limbs or appendages of which a typical segment bears one pair. They bite against one another from side to side, while the lower jaw of a backboned animal is moved up and down.

A second pair of limbs in the head region have given up the locomotor function and are in the form of blunt projections upon which large slime-glands open. The slime can be ejected to some distance, serving to secure small insects as food, and also as a means of protection. On the front of the head may also be seen two feelers (*antennae*), employed as organs of touch. There is a well-developed eye near the base of each of these. It may further be noticed that the air-tubes, though numerous, are feeble, and not particularly efficient.

### Centipedes and Millipedes

The animals included in this class are decidedly more specialised than *Peripatus*, and very typical members of their sub-kingdom. The body is clearly divided into segments, the limbs are distinctly jointed, and three pairs of them have been converted into jaws. A pair of fairly long antennae and two groups of simple eyes are to be seen on the head. A well-developed system of air tubes is present, and each of these has a spiral thickening in its lining, so that its walls are prevented from collapsing. They open to the exterior by a series of air-holes (*stigmata*) on either side of the body.

**Centipedes.** Centipedes are exceedingly active creatures of highly carnivorous habit [413]. They are flattened from above downwards, and each trunk-segment bears a pair of jointed legs, while every other one is perforated by a pair of air-holes. The two legs next the jaws have been converted into formidable poison-claws, rendering some of the tropical species (*Scolopendra*) [413], which may attain a length of over 8 in., dangerous even to human beings. The commonest British form (*Lithobius*) is small and short. It may often be found under stones or among garden earth. Another of our native types (*Geophilus*), a relentless enemy of earthworms, is extremely long and slender.

**Millipedes.** Millipedes are slow-moving vegetarians, devoid of poison-claws, and perfectly harmless. Their bodies are cylindrical [415], and each trunk-segment bears two pairs of

## NATURAL HISTORY

legs and possesses a pair of air-holes. Some of our small native species (*Julus*) are common in hedges, and curl up if alarmed, while certain greatly abbreviated millipedes (*Glomeris*) can roll up like a ball. The animal figured is one of the large tropical forms.

It might hardly be expected that the creatures under discussion would be capable of much parental solicitude, yet such is the case, at least so far as the mother is concerned. In the little British centipede mentioned above, the eggs, as laid, are covered with particles of earth cemented together by a sticky fluid. The small pellets thus formed are very inconspicuous, and there is great need for this, since the father centipede is an egg-eating cannibal of the most abandoned type.

Equally painstaking is the female of one of our native millipedes, though in this case the male is not a perverted egg-eater. She burrows into the ground, and constructs a little nest of earth, about the size of a hazel-nut, in which from 60 to 100 eggs are laid.

### Insects

This ubiquitous class includes more species than all the other groups of land animals put together. The body is short, and made up of a comparatively small number of segments, divided into three distinct regions—i.e., head, thorax, and abdomen. The head possesses a pair of antennae, two large compound eyes (and sometimes several simple eyes as well), and three pairs of jaws, differing greatly in character according to the habits. The thorax bears three pairs of legs, and in most cases two pairs of wings, while the abdomen is entirely or practically limbless. The air-tubes make up an exceedingly complex system, and open to the exterior by a limited number of air-holes.

Insects are among the most successful animals in the struggle for existence, and this is largely due to the very perfect arrangements for purification of the blood, every portion of which is in the neighbourhood of some of the air-tubes, so that carbon dioxide is eliminated as fast as it accumulates, and

fresh oxygen taken up in exchange. Hence the restless energy which spells success.

Many characters are made use of in classifying insects, the best known distinctions having reference to the mouth-parts, wings, and life history. As to the last, an insect—e.g., a butterfly—may hatch out from the egg as a larva that is extremely unlike the adult, into which it is ultimately transformed by radical changes constituting a "metamorphosis," or else—e.g., a cockroach—it resembles its parents from the first, and becomes adult by a series of comparatively slight changes. There are also cases of intermediate character.

The simplest way of classification is into the following nine orders, though specialists recognise a much larger number: (1) WINGLESS INSECTS (*Aptera*); (2) STRAIGHT-WINGED INSECTS (*Orthoptera*); (3) BUGS (*Hemiptera*); (4) FRINGE-WINGED INSECTS (*Thysanoptera*); (5) NET-WINGED INSECTS (*Neuroptera*); (6) BEETLES (*Coleoptera*); (7) MOTHS AND BUTTERFLIES (*Lepi-*

*doptera*); (8) FLIES (*Diptera*); (9) MEMBRANE-WINGED INSECTS (*Hymenoptera*).

#### 1. Wingless

**Insects.** This order does not include all insects devoid of wings—for some of these belong to other groups, and their ancestors possessed the power of flight—but only certain primitive forms representing an early wingless stage in the evolution of the class. They are small, insignificant creatures, which live under stones, bark, and

leaves, or in other sheltered places where they are likely to escape observation. Their mouth-parts are feebly developed, and there is no metamorphosis. Two groups belong here, the Tassel-tails and Spring-tails, often reckoned as distinct orders.

**Tassel-tails.** Tassel-tails are so named because there are generally some jointed bristles at the hinder end of the body, but a more interesting feature is the presence of small limbs on the abdomen.

There are many reasons for thinking that insects have evolved from centipede-like creatures by shortening of the body, establishment of three regions, and suppression of many of the limbs. Tassel-tails come nearest the supposed ancestral

412. PERIPATUS 413. CENTIPEDE

414. LEAF INSECT

Photographs by Prof. B. H. Bentley

415. MILLIPEDE

type. Like most primitive groups, they are widely distributed. One common species, the silver fish (*Lepisma saccharina*) [416], lives in brown sugar; others are found along the sea shore, on mountain snows, and in the recesses of caves.

**Spring-tails.** Spring-tails [417] also have a very wide distribution, and most possess a "spring and catch" arrangement, working on the principle of the jack-jumper which children make from the merry-thought of a goose. It consists of a sort of fork folded under the abdomen, with its prongs projecting forwards and held in place by a little projection.

beetles." are not beetles at all, and in spite of their disagreeable smell, are perfectly harmless creatures, so far as biting or stinging human beings are concerned. Our common kitchen pest is not native to Britain, but a destitute alien, while the larger ship-cockroach belongs to a different species. Some exotic forms are brightly coloured and attractive in appearance.

**Soothsayers.** The soothsayers or praying insects [see Plate facing page 3361] are characteristic of the warmer parts of the world, only one European species (*Mantis religiosa*) ranging pretty far north of the Mediterranean. They are excessively rapacious, and derive their name from the fact that the front legs are turned up and converted into organs for seizing prey, thus bringing about a supplicatory attitude, which has led to many superstitious ideas.

**2. Straight-winged Insects.** Some of the members of this large group are rather generalised — e.g., the cockroach—and should be studied first by those who wish to grasp the complexities of insect structure. The mouth [418] is a biting one, and the three typical pairs of jaws are easily made out—i.e., (1) the hard-toothed first jaws (*mandibles*); (2) the second jaws (*first maxillae*), with a cutting blade and a

420. GRASSHOPPER

The fore-wings have been modified into horny wing-covers, under which the delicate hind-wings are folded in a fan-like way when not being used. This is why such insects are

421. APPLE SCALE-INSECT  
a. Infested twig b. Female, much enlarged

In France, for example, it was formerly believed that these intelligent insects were able and willing to point out the way home to lost children.

Soothsayers are aggressively coloured, harmonising with their surroundings so as to be inconspicuous to their prey. A very interesting Malayan species has been described which lies in wait upon certain pink flowers, turning up its tail over its back to display the similarly coloured

## NATURAL HISTORY

under side. Even the legs are modified to heighten the effect. When the flowers wither, the insect seeks a fresh lair, and turns down its tail so that the brown upper side is exposed to view.

Stick and leaf insects are vegetarian forms living in warm climates, and resembling the objects after which they are named both in colour and shape; no doubt a protective device [414].

Earwigs differ in many ways from other orthoptera, and are often placed in a separate order. The wings, for instance, are folded up in a very complicated manner. The common earwig, so detested by gardeners, is a very inoffensive insect, quite incapable of injuring the human ear, as is so commonly supposed.

**Leapers.** These include grasshoppers, locusts, green grasshoppers, and crickets. The first of them [420] may be recognised by their short antennae, and they also possess organs of hearing in the base of the abdomen. The pleasing chirping of our native field

425A.  
SOLDIER

grasshoppers is the love-call of the male, and is produced by rubbing a beaded ridge on the inner side of the thick part of the hind leg against the wing cover. Locusts are notorious on account of the huge swarms in which they from time to time appear, with disastrous results to vegetation.

Green grasshoppers [see Plate] are distinguished from the foregoing by their long antennae

and the position of their organs of hearing, which are situated in the front legs, just below the knee.

When they possess chirping organs, these are placed at the bases of the wing covers.

**Crickets.** Crickets agree with the members of the last group as regards antennae, ears, and chirping organs, but

differ in minor respects. There are, for example, jointed bristles projecting from the tip of the tail. Our best-known native species is the house cricket (*Gryllus domesticus*), which has

424. FRINGE-WINGED  
INSECT (magnified)

even attained a sort of popularity. Two other species live in our fields. But the most extraordinary member of the group is the mole-cricket (*Gryllotalpa vulgaris*) [see Plate], found in the South of England, a burrowing and largely carnivorous form. Its fore feet are modified into efficient spades, and the female is an exemplary mother.

3. **Bugs.** Despite the unpleasant associations conjured up by the name of this order, many of its members are very attractive in appearance, and unobjectionable in their habits. The wings vary in nature, and are sometimes absent, but the mouth parts are very characteristic, forming a long, pointed "beak," used for piercing and sucking. The first jaws are sharp

stylets, grooved on their inner sides for conducting fluid to the mouth, and the second jaws are also pointed rods. The third jaws are modified into a kind of sheath, which encloses the others. There is only a partial metamorphosis.

Plant-bugs [419, and see Plate] feed upon vegetable juices, and all four wings are of membranous texture. The largest of them are the cicadas, which inhabit warm countries, and are noted for the loud chirpings of the males. There is a large eye at either corner of the broad head, and three small jewel-like ones on the front of it. The wingless young live underground, and in one North American species (*Cicada septendecim*) seventeen years elapse before they make their way to the surface and assume the adult form.

**Lantern-flies.** The long-nosed Lantern-flies [see Plate] are popularly supposed to emit a phosphorescent light, but this has not

422. WATER-  
SCORPION

a. Lower lip

425. ROYAL CELL OF TERMES BELlicosus OPENED, SHOWING QUEEN  
ATTENDED BY WORKERS

been proved. An interesting discovery has recently been made as to the use of the elongated snout. Owing to the presence of a transverse joint this can be bent up by pressure against the surface on which the insect rests, and used as a spring by which its owner is propelled into the air. We might well term the lantern-flies "nose-jumpers." Among their allies are the little Frog-hoppers, of which the larvæ live within the frothy masses often seen on plants, and known to country persons under the prosaic name of "cuckoo spit."

**Blight.** Plant-lice, or green-flies (*aphides*) or "blight," are to be found on all sorts of wild and cultivated plants (e.g., roses and geraniums), among which they play havoc. They are small creatures with a complicated life-history, including winged and wingless individuals. During the summer numerous generations are produced without previous fertilisation, and these are born alive. Fertilised eggs are laid on the approach of autumn. Propagation is so immensely rapid that the tenth generation sprung from a single egg, if they all survived, would collectively weigh as much as 500 million men. The vine-louse (*Phylloxera vastatrix*) is one of the most destructive members of the family.

The curious Scale-insects [421] include some familiar British pests, and are so called because the female is generally sheltered under a scale-shaped shield. The exudations from the bodies of various species are of economic value. Of this nature are the "ground pearls" of the West Indies, which are simply insects of this kind enclosed in glassy or shelly coverings. A sweet substance—"honey-dew"—excreted by species native to the Mediterranean region is probably the "manna" of the Old Testament.

Other scale-insect products are white wax in India and China, shellac in India, and cochineal in Mexico, Central America, and Canary Islands.

**Water-bugs.** Of the remaining families of the order some include winged and others wingless forms. In the former case the fore-wings are hardened into protective sheaths for the hind-wings, but their tips always remain membranous. An example of this is afforded by the Water-bug, of which some few have been found living on the surface of the open sea, a very exceptional habit for insects, which are primarily land forms. Some of the freshwater types are among the

most interesting inhabitants of our ponds and streams. All are markedly predaceous. Gliding along the surface may be seen the long-legged needle-bugs (*Limnobates*) and skaters (*Gerris*), while the little water-boatmen (*Notonecta*) swim on their backs, using their specialised hind legs as oars.

428. CADDIS-FLY AND LARVA

Water-scorpions possess seizing fore legs and a slender breathing-tube projecting from the tail, which is from time to time protruded above the surface to take in air. Some (*Nepa*) are broad and flat [422], others (*Ranatra*) of slender form. The eggs of the latter are elongated, with a pair of bent threads at one end, which have a special use. The female stands upon a floating leaf and bites a little hole in it, through which the egg slides and remains hanging from the under side of the leaf, anchored by the threads [423]. Bugs and Lice are wingless Hemiptera.

**4. Fringe-winged Insects.** These are very minute creatures, with sucking mouth-parts and four narrow fringed wings [424]. The feet are swollen into bladders at their tips. These insects may often be seen creeping about flowers, and the corn-thrips (*Thrips cerealium*) is one of the pests by which our corn crops are damaged.

**5. Net-winged Insects.** In this interesting order the mouth-parts are of biting character, and there are four membranous wings, traversed by a complicated network of veins. The amount of metamorphosis varies greatly in different cases. The numerous families are arranged by many specialists in several separate orders, and they include termites (white ants), death-watches, dragon-flies, may-flies, caddis-flies, antlions, and lace-wing flies.

**Termites.** These light-shunning insects, often erroneously called "white ants," are particularly abundant in tropical countries, and notorious for their ravages on wooden articles. They live in communities, including several kinds, or "castes" of individual, and their social life is often exceedingly complex. One of the most extraordinary is an African kind (*Termes bellicosus*) [425], which erects mound-like dwellings as much as 20 ft. high. The increase of the community is the duty of a single male and female, known as the "royal pair." The abdomen of the queen is swollen to an enormous size owing to the vast number of eggs it contains. The other duties of the monarchy are performed by "workers" and "soldiers" [425A].

427. LIFE HISTORY OF A MAY-FLY

a. Eggs b. Young larva  
c. Larva d. Cast skin  
e. Sub-imago f. Cast skin  
g. Imago

Most termites, in accordance with their light-shunning habits, are either blind or possess imperfect eyes; but an exception to this is afforded by individuals belonging to a Natal species (*Termes havilandi*), which issue from their burrows in broad daylight to cut grass and acacia leaves. These are employed in mushroom culture, as is described elsewhere for some of the true ants.

**Death-watches.** These are little insects which live in old woodwork or books. The lesser death-watch (*Atropos divinatoria*) is supposed, by tapping with its head, to make ticking noises with which many superstitious ideas have been connected. It has been suggested that the sound is of the nature of a love call. Some authorities think that it is due to quite another and somewhat larger insect, the greater death-watch (*Anobium*), which belongs to the beetles.

**Dragon-flies.** Unjustly called "horse-stingers" by countryfolk, dragon-flies [see

Plate] are exceedingly beautiful insects, with four powerful wings, by means of which they rush through the air as

living darts, glittering like silver and jewels in the sunshine. Their eyes are of enormous size, and with their powerful jaws they seize insects on the wing.

The female dragon-fly lays her eggs in water or on water-plants, and the wingless young [426] lead an aquatic life. They are exceedingly voracious, and grip their prey by means of the lower lip (united third jaws), which is modified into a seizing apparatus. When not in use this can be folded up like a carriage-step. After attaining its full size the rather repulsive looking young insect climbs out of the water on the stem of a plant, and remains motionless. Very soon after this its skin splits open along the back, and the adult dragon-fly emerges.

**May-flies.** May-flies [427] are known to the general public as insects which have but a brief tenure of life in the adult, or imago stage, and serve as excellent bait. They may be seen dancing in countless numbers in the sunshine, and do not feed, devoting themselves entirely to egg-production. The males of some species are provided with special "courtship eyes," which help them to discover suitable mates. Two or three slender tails at the tip of the abdomen are very characteristic.

During the early part of their existence May-flies, like their cousins the dragon-flies, are aquatic, burrowing, running, swimming, or climbing, according to the species. Many are carnivorous, while others swallow mud for the sake of the nutritive matter it contains. They

breathe by very curious gills, traversed by numerous air tubes. When their feeding days are over, they float at the surface, the skin of the back splits, and the nearly matured winged adult (sub-imago) flies out of its prison, though it has to cast yet another skin before becoming a fully emancipated imago.

**Caddis-flies.** Caddis-flies [428] pass through a more considerable metamorphosis than other members of their order, and when adult are often known as "caddis moths" on account of the general shape and scaly character of the wings. The numerous eggs are deposited in water, embedded in a kind of jelly, and the larvæ which hatch out from them somewhat resemble minute caterpillars in appearance. They at once set to work to construct tubular homes by cementing together particles of sand, bits of rush, or other foreign matters. Their dwellings are of spiral shape, in certain tropical forms. Some of them appear to be vegetarians, but others make silken nets wherewith to snare small aquatic animals [429].

After a time the larva barricades the opening of its house with a screen of silk or cemented particles of sand or mud, and passes into the motionless pupa stage. Ultimately the pupa wakes up, so to speak, and bites its way out of the protective case. It floats up to the surface, and the sequel resembles the life history of May-flies.

**Ant-lions.** These are commonly of nocturnal habit when adult, and look like abbreviated dragon-flies, but without the same brilliancy and speed. The wingless larva [430], to which the name "ant-lion" is properly applied, is a highly carnivorous creature possessed of formidable first jaws, which catch ants and other insects in a very ingenious way. It digs out a conical pit in a sandy place, throwing out the material with its broad head, and lurks at the bottom of this, buried from sight

with the exception of its jaws. Unwary insects which step on the sides of the treacherous gulf quickly slide down to their destruction, and it is said that the wary larva throws sand upon them to hasten the descent. Pierced by the uncompromising jaws, their juices are sucked out for the benefit of the enemy. After attaining its full size the ant-lion makes a protective case by cementing sand grains together with silk, and gradually changes into the adult form.

**Lacewings.** Lacewing flies [see Plate] are beautiful little creatures with gauzy wings, and eyes that shine like gold. The eggs are laid on

the leaves of various land plants, each at the end of a long stalk. The wingless larvæ are known as "aphis-lions," on account of the havoc they play among plant lice (*aphides*). Some of them creep about clothed in the skins of their victims, which are sucked quite dry.

Continued from  
page 3230

By Dr. C. W. SALEEBY

WE insist upon the experimental side of Young's work because, though he was primarily a theorist and a man of imagination, he recognised that merely to suggest an analogy between the behaviour of water waves and that of light under certain conditions was to do practically nothing. Furthermore, Young is a conspicuous instance of the truth that a prophet is not without honour save in his own country, for he was honoured in France for many years, during which he was thought to be a trifle at home. The first phenomena to which he applied the principle of interference were the colours which, under certain conditions, are produced by striated surfaces. (*Striae* are parallel lines of depression or elevation.)

**Experiments with Sunlight.** Then Young went on to study the colours of thin plates—*e.g.*, the colours produced by thin plates of colourless glass when they are pressed together. Young also tried to produce interference experimentally by admitting sunlight through two small holes into a dark-room. He failed, however, and we now know why. He failed because the streams of light so admitted had no definite connection with one another, nothing corresponding, for instance, to the interval of half a wave length to which we have already referred. The consequence is that though, as we are now sure, interference occurs, its results are not obvious. Admirable results are obtained, however, directly the experiment is improved by the use of only one hole, and the passage of the light so obtained through a screen containing two little holes side by side. Regular and visible interference then occurs—this explanation of the phenomena having been carried some way by Young and brought to perfection by Fresnel.

**Soap Bubbles.** We must next proceed to the study of the simplest and, in a sense, the oldest of interference phenomena—those which were studied exhaustively as far back as the time of Newton; also, we shall find that facts of the utmost interest and value are to be derived from the study of objects which most of us may never have considered worthy of serious study—namely, soap bubbles.

Everyone is familiar with the fine colours produced in a film of soap blown into the form of a bubble. To the eye of the physicist soap bubbles are of the utmost interest; nor is the interest confined to the colours which they show. Plainly, the soap bubble illustrates the action of molecular forces which hold the particles of the film together. Just a century

and a half ago it was shown that a soap bubble tends to contract, so that if one relaxes the pressure at the end of the tube, the bubble will become smaller. The force so exercised is that force of surface tension which has already been described as a general property of the surfaces of liquids.

**Light and Soap Bubbles.** Here, however, we cannot return to this aspect of the questions suggested by soap bubbles. For our present purpose we have to note merely the fact that the bubble is a spherical film which has an appreciable, though small, thickness. The film has two surfaces, an inner and an outer, both of which are exposed to air. The important matter for our present purpose is to consider the behaviour of light in relation to this film and its surfaces.

The soap is not the important thing, for we do not see such colours in an ordinary solution of soap. The essential thing is that the soap is spread out in the form of a film. Indeed, the same phenomena are shown by other films. Many liquids poured upon water will spread themselves out into a thin film that shows these colours. They are also shown by plates of various transparent substances if these are capable of being made thin enough. In other words, the soap bubble merely provides us with a familiar and beautiful illustration of what we may call, in general, the colours of thin plates. We may therefore leave it and discuss the subject in more general terms; but before doing so we may note one striking phenomenon exhibited by soap bubbles and explained by Young's principles. This can be shown either by a soap bubble or, as is more convenient for many purposes, by a film of soap spread out within a small ring or frame made for the purpose. These soap films are very largely used for experiment and illustration. If, then, we take a soap bubble or a soap film held vertically and protected from currents of air, and watch it, we find remarkable consequences as it proceeds to drain, thus causing its uppermost part to become very thin. We find that this thinnest part becomes black; if it can be seen at all it is only by light reflected from particles of dust on its surface. This fact can be perfectly explained in terms of interference, as we shall see.

**Newton's Coloured Rings.** The appearance which goes by the name of Newton's rings must often have been observed by any reader who has done work with the microscope. If one takes two perfectly clean cover glasses—very thin pieces of glass used in microscopy for covering the object to be examined—and presses them firmly together, a series of coloured rings will be

seen to spread from the point where the pressure is greatest, and to widen out as the pressure is increased. These rings of colour are due, we must conclude, to the passage of light through the very thin film of air enclosed between the two cover glasses. Following various physicists, Newton set to work to ascertain the precise relation between these rings now known by his name and the thickness of the film of air that produces them. His method was to place a flat piece of glass upon the convex face of a very slightly curved plano-convex lens. This arrangement gave him a film of air which regularly, but very slowly, increased in its thickness as one passed outwards from its centre. Under these conditions Newton obtained a series of coloured rings, all concentric, the centre being at the point of contact between the two pieces of glass. Obviously, the next proceeding was to use light of one colour instead of compound white light. When Newton did this he found that the rings he obtained were alternately coloured and dark. The experiment is always a striking and beautiful one; usually one employs a brilliant yellow light which yields a splendid series of black and yellow rings. But the size of the rings was not the same with all kinds of light. With light from the red end of the spectrum the rings had a large diameter, but as the various colours were gone through up to blue, the rings became smaller and smaller. This fact suffices to explain the appearance shown with white or compound light. The rainbow effect of the colours thus obtained is simply due to the sorting out of its different constituents.

**Explanation of Newton's Rings.** We need not here concern ourselves with Newton's own explanation of his rings, because that explanation was conceived in terms of his corpuscular theory of light, which we now know to be erroneous. Further experiments, devised for the purpose, also proved that Newton's explanation was inapplicable.

In terms of the wave theory the facts can be satisfactorily explained. We have merely to conceive that some of the light is reflected at the upper surface of the film, and some at its lower surface. (In the case of the soap bubble, read *outer* and *inner* for *upper* and *lower*.) We have now merely to apply our general principles of interference. At the points where the film is of such a thickness that the two reflected streams of light differ in phase by a wave length exactly, or by a multiple of their wave length, they will reinforce one another, with the consequence that we shall see a bright ring. But, at other points, immediately placed, the film must be of such a thickness that the two streams, reflected from the two surfaces, differ in phase by half a wave length, or by an odd number of half wave lengths. In such a case, we shall have a state of affairs precisely similar to that conceived by Young in the case of waves of water in a channel. Light added to light will cause darkness—this being the only known instance in which two whites make a black—and a dark ring will be produced.

**Measuring Wave Lengths of Light.** Not only do Newton's rings provide a striking instance of phenomena which can be explained on the wave theory of light alone, but they also contribute to the wave theory of light by providing us with a means of measuring wave lengths. To discuss this in full would require more geometry than is desirable here. If, however, we consider the angle at which light may fall upon an air film of constant thickness, we shall see that interesting consequences must follow according to the angle of the incident light. The more oblique the incidence of the light, the less is the retardation of the ray which is reflected from the further surface of the film. It can be shown to follow that a complete geometrical discussion of these facts gives us means for measuring the wave length of light.

But there are entirely different methods of producing interference, and these lead us to further complexities. When we were discussing the history of the theories of light we noted how the rectilinear propagation of light and the occurrence of sharp shadows seemed to turn the scale against the wave theory and in favour of the corpuscular theory. We must now look into the question of shadows more closely, with reference not only to the wave theory of light but also to the phenomena of interference. If we make light travel through an extremely small aperture—having some reasonable proportion to its extremely small wave length—we find that the light behaves as it should behave, if it be a wave motion. It suffers diffraction, or *breaking apart*, in all directions; its behaviour in such a case is entirely opposed, evidently, to the corpuscular theory.

**Diffraction of White Light.** The consequence of diffraction in the case of white light is to produce coloured fringes, and this may be done by many means. Thus, we may employ a narrow slit, such as has already been instanced. If we make such a slit in a piece of cardboard and place it in front of a candle, and then if we make another similar slit in another piece of cardboard, hold it up to the eye and look through it at the light passing through the first slit, we shall see these fringes. But any opaque body of sufficient narrowness placed in the way of a beam of light will similarly cause diffraction. For instance, we may employ a narrow wire, and place it in the path of light coming through a narrow slit, and so may obtain diffraction fringes. These have been produced by the action of the two edges of the wire upon the light, and we shall best understand the phenomenon if we consider it in its simplest form, namely, that of the casting of a shadow by the edge of any opaque body. If we arrange an experiment, using light from a luminous point, we do not find, as we might expect, that the shadow has a sharp edge. On the contrary, there is a gradual transition from light to darkness, the light slightly invading the area which should be dark—and which would be dark if light were a stream of

corpuscles; whereas, on the other hand, the area which should be uniformly light shows a series of fringes which gradually fade away. The appearance seen then upon the screen is somewhat like the accompanying diagram, instead of being a sharp transition from dark to light.

THE EDGE OF A SHADOW

Fresnel readily explained these fringes in terms of interference.

**50,000 Lines to an Inch.** These facts are applied, in physical inquiry, in the employment of what are called *interference* or *diffraction gratings*. A grating may have various forms. It may consist simply of a series of fine wires, parallel and equidistant, or a piece of glass on which such lines have been ruled. Such diffraction gratings are now almost invariably employed in the spectroscope in place of the prism. Sometimes it is desirable to employ other transparent materials instead of glass. If glass be used the lines have to be ruled by a diamond, but a very large number of lines are necessary and so the diamond is soon worn down. One needs about fifteen or twenty thousand lines to the inch, though it is possible to have as many as fifty thousand. In order to economise in diamonds, a modern diffraction grating is not a transparent grating at all but a reflecting one, and is made of very finely ground and polished speculum metal, which a diamond can rule without wearing away nearly so soon as when glass is employed.

When we look at light from a narrow slit through a diffraction grating we see an image of the slit in the middle, while on each side of it is a series of coloured images which are more and more spread out the further they are from the centre.

**The Octave of Light.** Under these conditions it is possible, by means into which we cannot here enter, to measure the wave length of light of various colours. The approximate results may, however, be noted. The wave length of visible light shows, as we know, a range of slightly less than one octave—if we may borrow this convenient analogy from sound. The longest wave length that stimulates the retina, that of red light, is about one thirty-thousandth of an inch in length. The shortest appreciable wave length, that of violet, is approximately half as long, that is to say, one sixty-thousandth of an inch.

These figures appear at first to be incredibly small. Certainly, they are small when com-

pared with the wave lengths of audible sound, which have to be expressed in feet; but, on the other hand, one thirty-thousandth of an inch is not really so very small relatively to many distances which we are otherwise acquainted with. For instance, it is possible, as we have already seen, to make fifty thousand lines side by side within the space of an inch upon a piece of speculum metal. Again, this distance, when compared with the probable dimension of molecules—including even very large molecules—is actually very great indeed. In other words, we must remember that, in comparison with the size of the objects which we should like light to reveal, its wave length is hopelessly large.

**The Spectroscope.** We must now consider a new optical instrument, of very great interest in itself, and of supreme interest in consequence of the extraordinary insight which it has given us, and which it alone can give us, into many of the greatest facts of Nature. We already know, in general terms, what a spectrum is, and can readily guess that the *spectroscope* is none other than a device for forming and examining the spectrum of any light that we may care to examine. The most natural and simple method of forming a spectrum would, of course, be by means of a prism, and this we may briefly discuss, though we note that nowadays the prism has been largely replaced, for this purpose, by means of a diffraction grating. The two means effect the same end but by somewhat different principles, the prism causing dispersion of the various constituents of compound light because of the different speeds at which these constituents move through glass. The grating causes similar results because of the difference of wave length between light of various colours. If we ask ourselves, however, why different colours move at different speeds through glass, we shall see that the two methods really depend upon the utilisation of one and the same ultimate fact of light.

**What may be Seen with Three Prisms.** We have not space here to concern ourselves with the details of the structure of the spectroscope in its various forms, but we may briefly describe what is called the *direct vision spectroscope*, which can be obtained for a very

COMBINATION OF THREE PRISMS

small sum and can be carried about in the pocket, being scarcely larger than a spintharoscope.

We are already in a position to understand the principle of the direct vision spectroscope, for its essential part is a combination of three prisms, two of crown glass, and the third of flint glass, arranged as shown on the previous page, so that a spectrum is formed without the necessity of causing deviation as well as dispersion of the beam; this is admitted through an adjustable slit at the end of the spectroscope and a convex lens is used to convert the light from the slit into a parallel beam before it reaches the combination of prisms. The dispersed light now reaches the eye placed at the other end of the instrument.

Newton was practising spectroscopy in its simplest form when he made his classical experiment with the prism and the sunbeam, and though this at once established an epoch in our knowledge of light, it has led to developments, and notably to astronomical developments, of which even Newton could scarcely have dreamed.

**The Lines of the Spectrum.** When we examine the spectrum of sunlight, we find various dark lines upon it. These have long been known, and were first exhaustively studied by the physicist Fraunhofer. He made a careful list of them, and gave them names, employing the letters of the alphabet for this purpose. These dark lines of the spectrum of sunlight, and of light from various other sources, have revealed to us certain truths concerning the chemistry of the universe in general, and we must study their production with the very greatest care. Let us begin by considering spectra that are much more simple than this of sunlight—which, as a matter of fact, is almost infinitely complex. Equipped with the spectroscope, we can examine the light given out by any luminous body, and we can make various bodies luminous for this purpose. We then make a remarkable discovery as to the fundamental distinction between two different kinds of spectra. When we have appreciated this distinction, we shall be on our way towards understanding the principles of what is called *spectrum analysis*, and of realising the significance of the dark lines that are found in the spectrum of sunlight.

**The Two Kinds of Spectra.** We find that spectra are of two kinds. In certain cases, the spectrum is a continuous band of colour. In other cases, it consists merely of a series of coloured lines, between which there are dark intervals. The spectra of the first kind we call *continuous*, and those of the second *discontinuous*. We further discover the very simple law that continuous spectra are produced by luminous solids, while discontinuous spectra are produced by luminous gases or vapours. We shall afterwards see how this simple statement led to one of the most significant and remarkable astronomical discoveries of the nineteenth century. If we attempt to interpret the meaning of discontinuity or continuity of a spectrum, we see that a luminous solid must necessarily, since its spectrum is continuous, be giving out light of all wave lengths—within certain limits. These limits apply to a luminous gas or vapour also, but such a gas or vapour

differs from the solid in that, within such limits, it gives out light only of certain particular wave lengths, and of none other. Hence the dark intervals between the bright lines of the discontinuous spectrum of a glowing vapour or gas.

**Sir William Huggins's Discovery.** Some forty years ago, the most distinguished of astronomers now living, Sir William Huggins, applied this fact of the two kinds of spectra to a great astronomical problem—the nature of the nebulae. He demonstrated the truth of the contention, then supported by an amateur called Herbert Spencer against all the astronomical authority of the time, that what appeared to be nebulae or clouds of gas are *really* nebulae, and are *not* merely star clusters, which are so remote that the telescope cannot resolve them into their constituent stars. Not only so, Sir William showed how the quality of the spectrum changes, becoming intermediate between the discontinuous and the continuous, as the nebula becomes resolved into planetary or solar masses. This is not, of course, to say that the process of celestial evolution was observed in any given case, but that various celestial bodies seemed to illustrate various stages in this evolution.

**Seeing an Atom.** Now, when we come to look more closely at the discontinuous spectra of gases, and find that they vary in different cases, we discover that in the spectroscope we have an optical instrument which can enable us to accomplish, in a sense, the feat of seeing atoms which the microscope is impotent to perform. Similarly, also, where the telescope fails us, the spectroscope is not at a loss. Of these three instruments for seeing with, the spectroscope is indeed incalculably first in its power of insight.

Let us then take some of the vapour of sodium and examine it by means of a spectroscope. It will suffice to put a morsel of salt in a spirit lamp and examine the characteristically yellow flame which is produced. Any sodium salt will act similarly. The spectrum produced has the most remarkable characters. There is darkness everywhere except for a pair of brilliant yellow lines placed very close together and having the position corresponding to the yellow part of the spectrum of sunlight. We may take any number of other instances, and we always find that each of them has its own characteristic light. The differences between these various kinds of light must be referred to atomic differences, plainly. They do not depend upon the nature of any *compound* that we may employ for examination, but solely upon the nature of the *elements* in those compounds—solely, that is to say, upon the nature of the atoms in question. At present we can merely note, in a word, that the particular kind of light produced by a particular kind of atom—the particular wave length, that is to say, of the ethereal vibration caused by that atom—is determined by the movement and behaviour of the electrons composing the atom. The new corpuscular theory of matter takes up the facts of spectroscopy and builds them, with so many other facts, into an organised and rational whole.

Newton noticed the dark lines in the spectrum of sunlight, but he does not appear ever to have asked himself what they meant. It was left to Fraunhofer to discover their tremendous significance. He showed that certain of the lines—the dark ones—in the spectrum of sunlight precisely correspond in position with certain bright lines which constitute the spectra of various elements. Thus, for instance, there is the most absolute correspondence between the double yellow line of sodium light and the double dark line or double gap in the yellow part of the spectrum of sunlight. Evidently coincidence could not explain these facts—they were too numerous.

**Sympathy in the Natural World.** When we were discussing sound we noticed how sounds of certain wave lengths could be picked up by vibrating bodies of suitable physical character. For instance, the A string of the piano will be thrown into sympathetic vibration if a tuning fork of the same note be sounded loudly near it. This principle will enable us to understand the now accepted and thoroughly verified theory which explains the correspondence between the dark lines of the solar spectrum and the bright lines of the various gaseous spectra. When we make the experiment we find that if the vapour of a given substance, such as sodium, be interposed in the path of light given off by another specimen of that same substance in a state of incandescence, or in the path of a continuous spectrum, the bright lines characteristic of the substance in question are precisely replaced by dark lines. Evidently the vapour is enabled to absorb the particular kind of light rays which correspond to its own composition, being, indeed, the very rays which it would itself give off were it made luminous. The only necessary condition for success in this experiment is that the radiant energy of the source of the original light must be greater than that of the body which is interposed between the original source and the eye.

**The Chemistry of the Heavens.** When we apply this principle to the results of celestial spectroscopy, we see at once that we are entitled to assert the existence of sodium, for instance, in the sun. As the light from the main body of the sun passes outwards it has to make its way through outer layers, which are in the gaseous state but are at a lower temperature than the deeper parts. We can interpret the dark lines corresponding to sodium in the solar spectrum only by supposing that there are atoms of sodium in the outer envelope of the sun which, by the principle of sympathetic vibration, are capable of picking out light of the wave lengths proper to themselves, and so leaving dark gaps in the spectrum of sunlight when it reaches us. This is not the place in which to discuss the main results of the examination of spectra on these principles. These results, however, constitute one of the most significant and stupendous achievements of modern science, for the spectra of the stars, and of comets also, contain dark lines, and thus we are actually enabled to discover the chemistry of the heavens. The subject

cannot be left here without the assertion of the stupendous fact that the sun and stars are made up of the same elements as are found in the very tissue of the human eye that perceives them.

**The Movement of the Stars.** Already we have referred to an illustration from sound in order to explain the principle by means of which certain of the revelations of the spectroscope can be interpreted, and there is another principle also illustrated in acoustics, and known as Döppler's principle. This we shall discuss ere long in the course of saying what still remains to be said on the subject of the *Pressure of Light*. If a source of light be moving towards the eye, the number of waves which reach the eye per second is increased; whereas, if a source of light be moving from the eye, the number is diminished. It was the application of this principle to the results of spectroscopy that enabled Sir William Huggins, in the year 1868, to discover the rate and direction of movement of stars which are moving *in the line of our sight*. If there be an insoluble problem in all science, this might have been thought to deserve that title. The magnificent erudition of Dr. Merz, to whose "History of European Thought in the Nineteenth Century" we have so often referred, comes once more to our service. Twenty-six years before Sir William Huggins's discovery, as Merz points out, a theologian called Bolzano, who was Professor of Religious Philosophy and a colleague of Döppler at Prague, wrote these prophetic words concerning the principle which is now known by his friend's name: "I foresee with confidence that use will be hereafter made of it in order to solve—by observing the changes which the colour of stars undergoes in time—the questions whether, and in which direction, and with what velocity, they move, how distant they are from us, and much also besides."

**The Boundaries of the Spectrum.** When a wide compass of the ethereal vibration, compounded into that great chord of harmony, the visible part of which we call white light, is analysed by the spectroscope, or sorted out into its various kinds, it must necessarily be that many notes are to be found beyond either end of the visible part of the spectrum. The radiant heat mixed up with the sunlight, for instance, is put into its place by the spectrum, as also the rays which lie beyond its violet end. Thus, the use of the spectroscope affords a splendid opportunity for studying many of the notes of the ethereal keyboard that lie beyond our range of immediate sensation. If, for instance, we use a screen painted with quinine sulphate instead of an ordinary white screen, and throw analysed sunlight upon it, we shall find that light is reflected from the screen at a point well beyond what was formerly the limit. Similarly, there are various substances which, when placed not in the course of the visible light from the prism but just beyond its violet end, become visible.

The name applied to the remarkable character thus displayed by quinine and many other substances is *fluorescence*. This word is somewhat loosely used in common speech, but it has a precise physical meaning. The only valid

explanation of the behaviour of the quinine upon the screen in the experiment we have quoted is that it transforms the ultra-violet rays, which are too short to be visible by our eyes, into light of longer waves which we can see. Many bodies absorb violet rays and emit them as green or red rays. It is an extremely noteworthy fact that fluorescence was first observed (by Sir David Brewster) in an alcoholic solution of *chlorophyll*, the familiar green colouring matter of plants. When sunlight passed into this, its course was marked by a red streak. Fluorescence is, as the reader may guess, of extreme interest in relation to the new theory of matter, but we cannot here discuss it at any greater length; we may merely note the observation of Sir James Dewar, that many substances which exhibit no fluorescence at ordinary temperatures show this property in a very high degree when they are lowered to such temperatures as that of liquid air.

**Light Without Heat.** Concerning the violet and ultra-violet rays, we must here note further merely that they are practically without any heating action, thus contrasting markedly, as we shall see, with the rays at the lower end of the visible spectrum. As regards chemical action, however, the converse is true, that of the ultra-red and the yellow rays being negligible, while the violet rays, as every photographer knows, are extremely potent in this respect—as also are the ultra-violet rays.

There are dark lines—if such a term be applicable—in the spectrum of ultra-violet light, as photography has proved.

Quite recently it has been shown that these rays, besides having a great value in astronomical research, enabling us by the camera to see stars which we could not otherwise see, are of very great interest and of very great therapeutic value in relation to certain conditions of the skin of man and lower animals—or, rather, we should say, in relation to living tissues in general. Here we shall briefly discuss the recent application of this property in modern therapeutics.

**Light and Health.** The application of different forms of light to the treatment of disease constituted the lifework of Prof. Niels Finsen, of Copenhagen, who died in 1904, in his forty-fourth year, having accomplished more during the course of a terribly disabling disease than ten average healthy men accomplish in a lifetime. Recognising the initial fact that it is in virtue of sunlight that we live at all, and especially in virtue of the blue and violet rays, Prof. Finsen began the first systematic inquiry of the relations of different kinds of light to living matter of various kinds. His first piece of work was to study the action of light upon the development of the skin eruption of smallpox. He believed that this eruption was almost entirely dependent upon the chemical action of the blue and violet rays, and he therefore introduced what is called the red light treatment of smallpox, permitting only red light to visit the patient's skin. The study of any remedial measures upon

smallpox is, however, so much complicated by the effects of vaccination that it is still uncertain whether the red light treatment can really be credited with the successes which it appears to gain. Then Finsen turned to lupus, the extremely superficial disease of the skin which is due to its local infection by the tubercle bacillus—the same germ as that which causes consumption. Finsen discovered that sunlight (or, rather, certain constituents of the rays of sunlight) is able to arrest the progress of this disease. His own belief was that these rays kill the bacilli, while many other observers think that they act by stimulating the patient's tissues so as more efficiently to resist the bacilli, and thus that they cure the disease by helping the patient to help himself. This question, however, does not concern us here.

**The Electric Light Bath.** Finsen began by using direct sunlight, but he afterwards found that the electric arc was as efficient and much more convenient. By the initiative of Queen Alexandra, her countryman's treatment was transplanted a few years ago from Copenhagen to Whitechapel, and we may briefly describe its principles as they are now put in practice at the London Hospital. The source of light is a 60,000-candle power electric arc lamp, from which there proceed four telescope-like tubes, each directed towards a patient, who sits or lies at his ease. By means of the lenses in each tube the light is focussed until it covers an area about the size of a sixpence. If no special precautions were taken, the patient would, of course, be fearfully burnt—if, indeed, he were able to tolerate the heat at all. It is absolutely necessary, therefore, to adopt some device which will absorb all the rays that convey or consist of heat, while allowing the others to pass through.

**Glass and Crystal.** This is accomplished by making the light pass through a double layer of rock crystal, the two crystals enclosing a constantly moving stream of cold water. This absorbs the heat, but does not obstruct the ultra-violet rays. The reader will ask why glass cannot be employed in place of the crystal. The answer is that glass is opaque to ultra-violet rays, and would therefore be useless for this purpose, while rock crystal allows them to pass freely through. It is quite impossible to attempt any ultimate explanation of the reason why glass and rock crystal differ in this respect, but the fact is an important one not merely in reference to the Finsen treatment. People are often recommended to use what is called *pebble* in place of glass as the material for making spectacle lenses. But oculists have an important criticism to pass upon this practice. They point out that while glass freely allows the passage of those constituents of light to which, as we have seen, the retina is most sensitive, it cuts off the ultra-violet rays, which may sometimes be injurious to the eye. Pebble, on the other hand, permits the ultra-violet rays to pass, and its use is therefore as undesirable in the case of sensitive eyes, as it is desirable in the application of the Finsen treatment.

ART

23

HISTORY OF ART  
continued from  
page 3234

By P. G. KONODY

THE term "Gothic" as applied to art does not signify a style introduced by the Goths, but was first used by the Italians of the Renaissance more or less as an opprobrium, as a synonym of "barbarous," with reference to the artistic style of the despised Northern nations at a time when all true culture was thought to be necessarily founded on the antique.

**The Pointed Arch.** Just as the round arch is typical of the Romanesque, so the pointed arch is the characteristic feature of the Gothic style in architecture. Yet it is at times difficult to draw the line which separates the one from the other, as the pointed arch was not entirely unknown in Romanesque architecture, especially in the regions which were in direct touch with the Saracenic race. Moreover, the transition from the one to the other was gradual, and many twelfth century churches show elements of both styles.

The pointed arch was at one time believed to be the invention of the Northern mind, but there is no doubt now that the principle was derived from Saracenic sources, though the full development of its possibilities must be put to the credit of the builders of mediæval France, England, and Germany. In the Orient the pointed arch had been used as a playful ornament to relieve the monotony of bare walls. In the North it was developed into a new architectural system which, through the subordination of the allied arts to architecture, exercised a decisive influence on sculpture and painting.

Stability is the most important consideration in architecture, and the necessity of structural soundness leads to the logical development of every style in building. Thus the weight of the barrel vaults demanded solid, heavy masonry in Romanesque buildings, since the whole pressure of the domes and vaults had to be carried by the walls. Hence the preponderance of solid masonry over the openings. The Gothic vault, based as it is on the pointed arch, relieves this pressure by distributing it over the projecting ribs, which rest on strong piers or pillars, and consequently gives wider scope to the articulation of the walls. Gradually the solid masses of masonry disappear, until the openings for doors, windows, rose windows, etc., are more in evidence than the walls. But though the

actual weight of the vaults finds sufficient support in the piers, the lateral pressure, or thrust, of the pointed arch demands a new counteracting member—the oblique prop, or "flying buttress," which is so distinguishing a feature of the exterior of Gothic cathedrals. The flying buttress again needs the support of the vertical buttress, which is weighted down by the pinnacle [50]. It might thus almost be said that in the Romanesque style the decorative features are conditioned by the structural system, whilst in the Gothic style a new structural system is the necessary outcome of a new decorative feature. Or, in other words, stability was the law of classic and Romanesque architecture, and elasticity or balance of the Gothic. In Gothic vaulting, for instance, the

ribs, an essentially decorative feature, are the important element, and the curved surfaces of the vaults may be removed without affecting the structure. In the Roman vaults the ribs have no structural function and would collapse with the removal of the curved surfaces.

**Gothic Cathedrals.** As the walls decreased in massiveness, the horizontal gave way to a vertical tendency of the buildings, which rose to loftier heights, the eye being carried heavenwards by the serried vertical lines of the buttresses, turrets, pinnacles, and the crowning glory of the tall spire. It is this striving towards the infinity of space that

makes the Gothic cathedral the noblest expression of the lofty aspirations of Christianity.

Another result of the adoption of the pointed arch was the possibility of varying the height of the arch regardless of its width, a liberty which was not allowed by the semicircular arch. This did away with the necessity of square compartments, which prevailed in Romanesque vaulting; the nave could be given the same number of compartments as the aisles, which again left greater freedom to the play of fancy in the plan, and the general effect of the interiors became more varied and animated. The profuse use of stained glass helped to enrich the interior, whilst the exterior allowed the full play of inventive fancy in the countless carved stone traceries and ornaments, statuettes and reliefs and pinnacles, which, in course of time, transformed the whole building into a lace-like

50. SECTION SHOWING THE GOTHIC SYSTEM OF VAULTING, FLYING BUTTRESS, BUTTRESS, AND PINNACLES

gossamer web of stone tracery and sculptured ornament. To show the extent to which this applied decoration was carried, it is only necessary to state that the reliefs, statuettes, and stained glass windows of Chartres Cathedral alone contain some 10,000 figures, and that the exterior of Milan Cathedral carries upwards of 2,000 statues carved in marble [54].

**The Three Gothic Periods.** The two countries in which the Gothic style received its first impetus and reached its highest efflorescence are France and England. In both countries Gothic architecture flourished from the thirteenth to the end of the fifteenth century, and may be divided into three periods, though the development proceeded on different lines on the two sides of the Channel. In France the three successive centuries coincide approximately with the Primary, or *Gothique*; the Secondary, or *Rayonnant*, so called from the wheel tracery of the rose windows, and the Tertiary, or *Flamboyant* style; in England with the *Early English*, the *Decorated*, and the *Perpendicular*.

Of the earliest style in France the first example of typical Gothic construction is the church of St. Denis, near Paris (1144). A little later in time, but thoroughly characteristic of the first period, are Notre Dame of Paris [53], St. Remy at Rheims, and the Cathedrals of Bourges, Chartres [56], Amiens, and Rouen. The wars with England acted as a check to French building activity in the fourteenth century, of which period St. Ouen at Rouen, and the unfinished church of St. Urbain at Troyes, are the most typical examples, whilst the Flamboyant development of the fifteenth century is best represented by St. Maclou at Rouen. During the close of this epoch secular architecture also advanced with rapid strides, and produced such masterpieces as the Palais de Justice at Rouen and the Hotel de Jacques Cœur at Bourges [58].

Early English Gothic can best be studied at Salisbury Cathedral [57], and in parts of Westminster Abbey—the choir [55], transepts, and first five bays of the nave. Noble proportions and simplicity in decoration are the chief aims of the period. The Decorated or fourteenth century style is recognisable in the interior by a more complex system of vaulting, and on the exterior by the larger clerestories and window openings and the increased splendour of the tracery. Some of the cloisters in Westminster Abbey, the Chapel of St. Etheldreda, in Ely Place, Holborn, and parts of the Cathedrals of Ely, Lincoln, York, and Lichfield may be quoted as notable examples.

The Perpendicular style of the fifteenth century has its name from the increased stress laid on the vertical line, which predominates to such an extent that one almost loses consciousness of the existence of walls. The clerestory windows

increase in size so much that no room can be found for a triforium, and they have to be strengthened by doubled mullions. Very often the stonework is reduced to a mere skeleton to hold the glass. Open timber roofs, richly carved and ornamented, are of frequent occurrence in the earlier Perpendicular period; whilst "fan vaulting"—so called from the similarity of the ribs to the framework of a fan—is characteristic of the later period. This fan-vaulting is a peculiarly English motif, and only very rarely found in other countries. The dazzling splendour of its effect is known to everybody who has been in Henry VII.'s Chapel in Westminster Abbey. St. Margaret's, Westminster, St. George's Chapel, Windsor, Westminster Hall, and the west fronts of Winchester and Gloucester Cathedrals [52] are instances of Perpendicular Gothic.

Germany, where the Romanesque style had taken very firm root, was comparatively reluctant to welcome the new ideas which were introduced from France. Cologne Cathedral, which was begun in the middle of the thirteenth century, is almost identical in plan with Amiens Cathedral. The cathedrals of Strasburg, Ratisbon, Treves, Vienna, Ulm, and the beautiful churches of Nuremberg are among the chief monuments of German Gothic; whilst numerous castles, such as that of Marienburg, town halls—Ratisbon, Brunswick, Münster, Lubeck—and private dwellings, of which many are still to be seen in Nuremberg, Cologne, and other old cities, testify to the artistic taste which prevailed in profane architecture. In domestic architecture the most characteristic features of the German Gothic are the very high and steep gabled roofs, which often exceed in size the actual walls, and the pretty dormer windows.

Frequently the upper storeys project over the ground floor. The ridge of the roof is either parallel to the street or at right angles to it. All these features combine to give an extraordinarily picturesque and quaint effect to the narrow streets of these old-world cities. Fig. 51 shows an oriel window, typical of many to be found in the streets of Nuremberg.

**Famous Town Halls.** In Belgium and Holland French ideas were adopted at an early period, and the splendid cathedrals of Antwerp, Tournai, and Brussels show to what extent these ideas were absorbed. But the genius of the race found its peculiar expression in profane architecture, as was only natural with this prosperous state of traders with their highly-developed civic institutions and guild system. The main features of the town halls are borrowed from ecclesiastical architecture, and even the church steeple finds its counterpart in the lofty belfry rising from the centre of the buildings. At the same time, the secular character and purpose of the civic building are never lost sight of, and these edifices are

**FAMOUS EXAMPLES OF GOTHIC ARCHITECTURE**

**52. Gloucester. 53. Notre Dame. 54. Milan. 55. Westminster. 56. Chartres. 57. Salisbury**  
*Photographs of 52 and 57, Wilson; 53 and 56, Neurdein; 54, Brogi; 55, Frith*

admirably adapted to public business. The town halls of Bruges, Brussels, Ghent, and Louvain are among the glories of Gothic architecture.

**Italian Gothic Churches.** The local conditions of Italy did not allow Gothic architecture to develop on parallel lines with the

58. HÔTEL DE JACQUES CŒUR, BOURGES

North, and though the pointed arch was extensively adopted, the full system, based on it, did not find favour south of the Alps, except in isolated cases like Milan Cathedral [54], the work, to a large extent, of German builders; and even here the absence of a lofty tower and the form of the façade are marked departures from the Northern prototypes. The abundance of such precious and effective building material as coloured marble, with its possibilities of use or incrustation, the hot climate, which imperiously demands solid walls with small windows for protection against the sun, and, above all, the classic tradition which was never quite eradicated, even when it was overshadowed by foreign influences—all these factors left their mark on Italian Gothic churches which retained more or less the horizontal tendency and the preponderance of solid masonry, decorated with stripes and panels of marble inlay, over openings. Moreover, the genius of the people could not dispense with large surfaces for pictorial decoration, and fresco and mosaic painting had practically ceased to exist in the North as a result of the masonry being reduced to a minimum, a mere frame for the stained glass work which had usurped the place of painting. Climatic reasons, again, did away with the necessity of steep roofs. The aisle roofs of Italian Gothic churches are generally masked by the screen-like west-front wall, the porch of which frequently projects, with columns resting on the backs of lions; and the dome is developed

to such grand proportions as the glorious cupola of St. Maria del Fiore in Florence.

The exquisite campanile of Florence, Ruskin's "Shepherd's Tower," is the perfect result of the blending of Gothic and local character. In Lombardy, where brick frequently took the place of stone as building material, the church of the Certosa di Pavia stands as a noble example of Italian Gothic, whilst of other churches it is only necessary to mention St. Maria Novella in Florence, and the cathedrals of Siena and Orvieto.

In secular architecture we have to distinguish between the massive, defiant, powerful Gothic palaces in Florence, such as the Palazzo Vecchio and the Bargello, and the playful treatment of Gothic motifs in Venice, which found its supreme expression in the Palazzo Cà d'Oro on the Grand Canal [59]. In the Doge's Palace the style attains to rare dignity, whilst the two colonnades by which it is adorned stand unrivalled for magnificence. The brick palaces of Siena are distinguished for their noble architectural articulation; witness the Palazzo Pubblico and the Palazzo Buonsignori. But, in spite of the temporary victory of an art ideal which had been more or less imposed upon the Italians by Northern conquerors, the Gothic style always remained alien to the spirit of the race, and only a slight impetus was needed in the early part of the fifteenth century to secure a lasting triumph to the rediscovered principles of antique architecture. The dawn of the Renaissance signified the death of the Gothic style in Italy.

**Spanish Gothic.** Spain derived her Gothic style in the first place from the neighbouring France. From the very first the Spanish builders adopted, with complete understanding, the severe constructive system of French Gothic; the sectional proportions often

59. PALACE CÀ D'ORO, VENICE

show Italian characteristics. The front of the churches was articulated in Northern fashion, and even openwork spires were not unknown; but at the same time the cross is frequently crowned by a dome, and rich Moorish ornaments are employed together with Gothic motifs.

By Dr. A. T. SCHOFIELD

WE have now to say something about the general consumption of beer.

**Beer-drinking Countries.** Beer is chiefly drunk in the United Kingdom, Germany, Austria, Holland and Belgium, and recently in Northern France also.

In Italy, less than 1 pint per head is consumed. All over the Continent the beer contains about half the amount of alcohol which English beer does.

Germany and Great Britain are the greatest brewing countries, the beer of the former being rather larger in quantity, if less in strength. The consumption in the United States is not half that in Germany per head, while in France it is not one-fifth. Bavaria drinks most beer of any state in Europe, the amount reaching 50 gallons per head, while Belgium comes next with 43. In Great Britain it reaches 30 gallons per head, 77 gallons of beer being drunk for every gallon of wine. The average strength is under 6 per cent. of alcohol, and the cost about 9d. per gallon.

The consumption of alcohol generally is enormous, and its importance well entitles it to be considered a little further, for though in this country comparatively little wine is drunk, as it is not a wine-growing country, the amount of beer and spirits used is very great.

All are agreed that alcohol in excess is a poison, but no other poison is taken so generally as a beverage and as an article of everyday use. In this, of course, lies danger, for where the dose that is poisonous begins and the dose that is harmless ends cannot be defined, as it varies so enormously in different people.

Just as our own country suffers from a plethora of meat, so does it suffer from excess in alcohol, and it is galling to see in the land of the degraded Turk a sobriety we cannot display at home.

**The Danger of Alcohol.** Alcohol is a stimulant and a narcotic like opium, though much less deadly in its effects. But it is the wrong sort of stimulant. It is the sort which makes the jaded organism put forth more strength, but it does not supply strength as food does. Moreover, alcohol not only does not give strength, like food, but it destroys the appetite for food itself. Its power as a stimulant is really ultimately due to its paralyzing effect on the nervous system.

Every part of our body—notably the heart—has an escapement action to prevent it from going too fast. Take the escapement off a clock or watch, and see how merrily the wheels and hands go round, though it can no longer keep time, and soon runs down. So with alcohol. It increases the action of the heart greatly, and the effect of this on an already

tired organ can be imagined. In large doses as a narcotic, it paralyzes the nerve centres themselves.

It used to be thought that alcohol was a food, but few think so now. It is true that it is made from sugar, which is one of the best foods and heat-formers in the body; and it used to be thought that alcohol increased the heat of the body, though it was known that even if it did so it stopped the combustion of other foods, and decreased vital action as a whole. Like sulphur, it might burst into a flame itself, but it put out the fire. But when it was discovered by the clinical thermometer that all feelings of warmth from alcohol were fallacious, and were simply caused by a rush of blood to the skin from the nerve paralysis caused by the spirit, and that the body was actually cooled and the temperature lowered according to the amount of spirit drunk, all claims for alcohol as a food had to be abandoned.

**Effect of Alcohol on the Blood.** Alcohol, therefore, gives neither strength nor heat, but it does check other vital processes, especially digestion, so that hunger may be appeased by it; but the blood becomes darker from its greater impurity, from the lessened metabolism, or oxidation, upon which life depends. We need not here discuss the effect of alcohol in excess, for we all know that it impairs the action, not only of the nerves, but of every organ in the body, and especially of the brain and higher nerve centres, so that in time it even alters the moral character.

But, so far, we have not said one word in its praise. Is it never a real help to the body?

One may answer, "Never to a really healthy body, but frequently to a weak or diseased one;" only, then it becomes more of a medicine than a beverage. Three-fourths of the stimulants drunk tend to the detriment rather than to the good of the human body. To the jaded they will, however, always be as popular as bill-drawing is to the impecunious. The one is a draft on health, and the other on wealth, and both lower and lessen the future resources, though both give immediate relief. Going to the brandy bottle is therefore radically unsound finance, and is very much like going to the Jews as money-lenders—both too often end in "going to the dogs."

**Tea.** Tea is the next most popular beverage in this country, being for some reason far more so than coffee. We are told this is because we do not know how to make coffee here; but we find sometimes execrable coffee abroad, and more so now than formerly, while the sweet Turkish coffee with its grounds is distinctly an acquired taste.

## HEALTH

The value of tea to this country is, as we have already pointed out, immense. When we consider that we drink on an average three pints, a day, and that before the introduction of tea and coffee the choice lay practically between beer and water, it will be seen what a boon the introduction of such a beverage was. When beer was the staple beverage, very exact manual work was almost impossible, and the extraordinary dexterity needed in the present day could never be attained and the reputation of this country for supreme excellence in making machines of precision never gained, had beer continued to be the skilled workman's only drink. Tea assists the nerves to do the finest and best work bodily and mentally, provided it be made in the way we shall describe, and only when taken in great excess is it deleterious.

Tea, coffee, and cocoa owe their value to three alkaloids—*theine*, *caffeine*, and *theobromine* (or the food of the gods). The two former are nerve stimulants, and the latter a muscular stimulant.

**The Tea Plant.** *Camellia thea*, or the tea plant, is a camellia with toothed oval leaves. The top leaf of bud or twig is the most valued and most tender, and makes Orange Pekoe tea. The larger leaves form Souchong, and the lowest Congou tea. In green tea the leaves are quickly dried over a wood fire; whereas in black, they are first fermented for twelve hours and then slowly dried over charcoal. When selecting tea, water poured over it will unroll the leaf and show if it be a small whole leaf or a large one cut up.

The total soluble matter in good tea is about 30 per cent. In the general use of non-alcoholic beverages other than water, milk comes first, then tea, then coffee, and then cocoa. In the seventeenth century tea cost ten guineas a pound. Ten years ago the consumption was over 7lb. a head per annum; it is now considerably greater. Brick tea made of tea-dust and leaves is eaten in Asia with butter as a food. Tea itself contains no nourishment. In China and Japan it is drunk as a pure beverage like water. In Russia it is flavoured with lemon; in England a cup of "tea" is really a nourishing soup made with milk and sugar. The theine constitutes about 3 per cent.

Of the tannin in the leaf, of which we hear so much, three-fourths is *soluble in boiling water*, and is, therefore, at once dissolved when boiling water is poured on the leaves. To have tea without tannin the water must not be above 180°. The bitter taste when tea has stood is due to a bitter principle dissolved with the rest of the tannin after some time. It forms an admirable beverage taken cold.

**Quality of the Water.** Hard water wastes one-third of the tea. The quality of water affects the tea greatly. Certain kinds of tea only yield their best properties to certain kinds of water. In England the character of the water varies greatly in different towns; the result is that the tea-dealers in each town are supplied with blends carefully prepared in London for the particular water of that town, as ascertained by experiment.

It is often a great mistake, therefore, to send to London for tea when living in the provinces; better results can, as a rule, be obtained by buying the best tea from the best local dealer.

Tea wastes least if the finest quality is used crushed or powdered into dust, such as is now sold in tabloids. Tea retards the digestion of meat and starch, and is best, therefore, taken apart from a heavy meal, although the slowing of digestion is not necessarily an evil. Hence, with the young and strong, meat teas are very popular.

Lake tobacco (if taken in excess), tea is least injurious when most adulterated. That from China has least tannin, Ceylon comes next, and India has most.

**Analysis of Tea, Coffee, and Cocoa.** In France and Germany coffee is drunk most; in Russia and England, tea; in Spain and Italy, cocoa. The following is an analysis of 1 lb. of each.

| CONSTITUENTS       | TEA. | COFFEE. | COCOA.          |
|--------------------|------|---------|-----------------|
|                    | oz.  | oz.     | oz.             |
| Water              | 4    | 2       | 2               |
| Theine or Caffeine | 1    | 1       | 1½ theobromine. |
| Albumen            | 2    | 2½      | 3               |
| Sugar              | 1    | 1½      | 1 starch.       |
| Tannic acid        | 4    | —       | —               |
| Fat                | 2    | —       | 8               |
| Mineral            | —    | —       | 1               |
| Gum                | 2½   | 1½      | 1               |
| Woody fibre        | 3½   | 5½      | 1               |

One would have thought that in this great country of tea drinkers, the making of tea in the proper manner would be universally known, but it is not so. The following sketch by the late Sir Andrew Clark will be recognised as true by scores of sufferers

**A Good Cup of Tea.** "When I go into a drawing-room, the lady of the house will say to me, 'Sir Andrew, you look so tired, do let me give you a cup of tea.' I say, 'Thank you, very much.' But the tea has stood for half an hour, and she remarks, 'I know you do not like it strong, Sir Andrew,' and then she pours about a tablespoonful of tea into the cup and fills it up with water. Now, I can't it positive cruelty to give tea like that to anybody, and I hope you will always set your face against such a beverage. Tea, to be useful, should be, first of all, black China tea. If you want, then, to have either for yourself or for your patients tea which will not injure and which will refresh, get black China tea, putting in the right measure—the old-fashioned teaspoonful for each person and one for the blessed pot. Then pour on briskly boiling water, and *within five minutes* you must pour out the tea, or it will become wicked instead of good. Let this patient, therefore, have half a pint of tea à la Clark, if you please."

Now this is all very well, but it is quite obvious it does not at all meet the whole case. If every one at breakfast or afternoon tea were ready with his cup to be filled only once five minutes after the tea was infused, all would get tea à la Clark. But no one who entered ten

minutes or half an hour afterwards, or who asked for a second cup, could hope for a taste of this matchless beverage. And yet breakfast and afternoon teas, when tea is mostly drunk, are two notoriously unpunctual and lengthy meals. Sir Andrew would hardly suggest a fresh infusion for each person, and failing this, bad tea must be drunk, if there be no better remedy. But there is; for the root of this evil is not in the tea standing, but in the tea standing on the leaves.

**Tea-leaves Left in the Pot.** One of the most curious survivals of senseless customs is that everywhere, for some utterly unknown reason, the tea-leaves are left in the pot, and the tea stands on them. They are always a nuisance, they cannot improve the tea, and the most ingenious devices have been patented to avoid their getting into the teacup, with very imperfect success. In the teapot they are ever blocking up the spout and embittering the temper as well as the tea, and yet no one has ever explained why they are kept in the teapot at all. If it be true, and it is so, that the maximum of good and the minimum of evil is found in tea which, made with fresh boiling water, has not stood over five minutes on the leaves, how is it that some genius has not arisen to direct that at this moment the tea should all be poured into a clean, hot teapot, and thence into cups as required? No doubt it needs a genius even to conceive such a simple remedy, but some day he will arise, and then all the tea terrors of the breakfast and tea-table will depart; and all hideous nightmares of nauseous bitter infusions and their consequences will be forgotten.

It is obvious that the length of time that the tea stands in a clean teapot is immaterial, and with this simple device, a man, for the first time in his life, may find his second cup of tea as wholesome as his first. Surely, this chapter is worth reading for the sake of this one piece of advice alone. It is so important that we have spent some time in pointing out its great value.

**Coffee.** Coffee is a plant allied to the cinchona (*Coffea arabica*). Roasting of the bean is essential, as it separates the caffeine from the tannin, changes the sugar and starch into caramel, and drives off the water.

Coffee is generally adulterated with 30 per cent. of chicory. When really good it requires one ounce to each large cup (making two cups of café au lait), and costing twopence; in England, an ounce is often all the allowance for a quart of coffee. It is a diuretic and sudorific, and delays digestion of meat, but not that of starch. It also allays hunger, and is a powerful nerve restorative. Coffee is best when freshly roasted and coarsely ground. It can be made as perfectly in a jug as in the most elaborate apparatus. The great essential is freshness and sufficient quantity.

**Cocoa.** Cocoa is the roasted bean of *Theobroma cacao*. Prepared cocoa has half the fat, which constitutes half the bean, removed. It is a good food, and the nibs can be infused like tea. The outer shells at twopence a pound

form a cheap nourishing beverage for the poor. Chocolate is made with sugar from the finer parts of the bean, and is a most digestible and nourishing food.

The great advantage of all these three beverages—tea, coffee, and cocoa—is that they are made with boiling water, thereby insuring safety from microbic poisons.

It may also be remarked that all three beverages—tea, coffee, and cocoa—are used both boiled and infused. Boiled tea is common at sea and abroad. Coffee is both infused and boiled, and so is cocoa. In each case the infusion produces a lighter and more digestible beverage. Boiling is more nourishing in the case of coffee and cocoa. There can be no doubt that infusion is better in tea.

Various temperance infusions are palatable and refreshing, their chief value being the simple fact that the water is boiled. Hop teas and beers (kops, etc.), treacle beer, and many other varieties are found in different parts of the country. Oatmeal and water is much drunk in the harvest field.

**Mineral Waters.** We now come to mineral waters of all sorts, and their variety is increasing every day. They are mostly described by their names. Potash and lithia contain potash and lithia; soda-water, as a rule, however, contains no soda; only in exceptional cases is it anything but a plain aerated water. Mineral waters are very refreshing and harmless taken in moderation. The water in them, though not boiled, is rendered safer by aeration, for carbonic acid gas destroys most germs. There is a danger in the use of syphons from some waters rapidly dissolving the lead of the taps. Some of the best firms take elaborate precautions against this subtle poison by having nothing but grain tin pipes (no lead) in their factories, and having no lead glass or exposed metal in their syphons, which have their taps glazed inside. These aerated waters are flavoured with varieties of syrup, so as to produce lemonade, ginger-ale, orangeade, etc.; their consumption is enormous, and is increasing rapidly.

We must not leave the general subject of temperance beverages without pointing out, since sugar changes by fermentation so naturally and rapidly into alcohol, that many of them—and especially home-made wines—supposed to be free from alcohol, are intoxicating. This arises largely through ignorance, and can only be safeguarded by either drinking these wines when quite fresh, or by stopping the alcoholic fermentation by such drugs as boric or salicylic acids. Many people are victims to home-made wine, believing it to be free from alcohol. Indeed, one of the largest manufacturers of these drinks has lately stated publicly that a large proportion of them are more intoxicating than lager beer, and that many of them are as strong as Bass's ale, containing more than 10 per cent. of alcohol. Another worker in the temperance cause states that cases of drunkenness from drinking "temperance drinks" are far from uncommon, particularly in the North,

## HEALTH

where herb and ginger beers are so popular. Young girls and children are allowed to drink these freely, under the belief that they contain no alcohol, and in this way a taste for strong drink may often begin.

**Effervescing Waters.** No artificial water is, however, to be compared with the natural pure effervescing waters, such as Perrier and Apollinaris. Here, the water is always pure, and the aeration is not so coarse as in artificial waters, so that they are more palatable and digestible. If these waters are bottled at the springs and uncorked upon the table, no impurity can enter them.

**Water.** And now we come to what is often a truly dangerous beverage, which is certainly neither food nor stimulant, but not seldom a poison—namely, water.

Water drinkers have fallen on evil days, and have to walk, or rather sip, warily. We have lately returned from a trip to Greece, Palestine and Egypt, and for six weeks no drop of ordinary water has passed our lips. Others have drunk the water of the country, and several have been very ill with typhoid, etc., and two have died. Of course, pure water is still obtainable, but gets scarcer every day as the population increases.

What, then, is a man to do? Boil the water, says one. Did you ever drink boiled water, and do you know boiled water keeps hot or lukewarm for a long time? And one generally wants cold water in a hurry.

**Are Filters of any Use?** Until the elaborate report on filters, in 1894, nearly every house protected itself—in imagination at any rate—by either a charcoal or a spongy iron filter. The idea in the former was to strain off the impurities, and in the latter to deoxidise them, but both proceeded on a false assumption that they had mechanical or chemical impurities to deal with, and not organisms. How very popular these filters were at the time! Almost every cottage had a glass charcoal block filter standing on the family Bible with the water tinkling as it dropped through.

The report on filters, in 1894, states that in

No 1 filter, of compressed charcoal the germs in tap water were increased ten times after filtration.

No 2 of asbestos cloth, the same thing occurred.

No 3, of carbon block, loose charcoal, etc., produced the same result.

No 4, of powdered and granular charcoal, the increase was innumerable.

No 5, of magnes carbide, the same.

No 6, of silicated carbon, the same.

No 7 (Maignen's) increased the germs a little, but cholera germs lived 32 days in it.

**Reliable Filters.** All other filters were worse, save three, which were perfect, and let no germs through after four days' running. These are now in use, and are the *Pasteur-Chamberland*, in which the water percolates through porcelain; the *Porous Porcelain Filter*, in which it does the same; and the *Berkefeld*, in

which it percolates through fused clay. These are quite safe, but slow in action. Yet even these require to have the tubes washed and boiled regularly, or they soon get choked and useless.

So the result is that all the ordinary filters with those well known carbon blocks simply form crowded nurseries for germs, and introduce absolutely ten times as many into the water as there were before, while the reliable filters only let the precious fluid through drop by drop, so that a thirsty man has to wait some minutes to get a quarter of a pint. What, then, is to be done?

The first comforting reflection is that many of us are still alive in spite of impure water, for fortunately but few of the countless germs we swallow are malignant. The best thing we can do is to get the water from as pure a source as possible, and when any suspicion arises or any epidemic is about, to drink only boiled fluids. Water for drinking should be soft and pure, and is best if slightly aerated. The best water to drink is fresh spring water, this, however, is a luxury that is rarer than good wine, and the bulk of the population have no idea what such water is like. On a recent visit to the Decade our exclusive drink was this delicious tap water though in London we never drink the tap water. Water receives impurities in four places. At its source, as in shallow wells, rivers, etc., in transit, from various contaminations; in distribution, principally from lead pipes in houses, and lastly in storage, from bad water, butts, or foul or uncovered cisterns.

When the water is doubtful or unpalatable, the only plan is to drink from syphons or to use natural aerated waters.

## DIETS

We have already pointed out in the course on physiology that the average man loses some 300 grains of nitrogen and 4,500 grains of carbon daily, and requires therefore this amount of foodstuff to replace it.

The following standard diets show roughly how this may be done.

| STANDARD DIETS               |         |          |              |
|------------------------------|---------|----------|--------------|
| Foodstuffs                   | In Rest | At Work. | At Hard Work |
| Albumens                     | 2.5 oz  | 4.5 oz   | 6.0 oz.      |
| Carbohydrates                | 12.0 "  | 14.25 "  | 16.0 "       |
| Hydrocarbons                 | 0.10 "  | 3.0 "    | 3.5 "        |
| Salts                        | 5 "     | 1.0 "    | 1.5 "        |
| Containing nitrogen          | 175 gr  | 320 gr   | 420 gr.      |
| Containing carbon            | 3,150 " | 4,700 "  | 5,450 "      |
| Producing food tons of force | 2,370   | 4,000    | 4,444        |

Ordinary food is half water, so the weights must be doubled and three pints of fluid added for a beverage. An average man requires to eat one-hundredth of his weight in dry food, and three-hundredths in water, or one twenty-fifth of his weight daily. Ordinary work lasts eight hours a day, hard work twelve.

**Annual Cost Per Head.** Let us bear in mind the general ratios are 1 part of nitrogen to 15 of carbon, or 1 part of nitrogenous foodstuff to  $3\frac{1}{2}$  of non-nitrogenous, and 1 part of fat to 9 of starch or sugar. The annual cost per head for food bought is said to be £7 5s., or about 5d. a day. Of course, this estimate includes all infants and children, and does not take into account the large amount of food that is grown by its consumer and not bought.

Women require usually 10 per cent. less food than men, and two children of 10 years are equal to a woman. One child of 14 years is equal to a woman, and a youth is equal to a man.

In comparative food values, one egg at 1d. is equal to 15 oysters costing 3s., while a quarter of a pound of steak costing 4d. is equal to 5 dozen oysters costing 12s. 6d. or half a gill of beef-tea costing 5s.

The least a working man can live on in health is  $1\frac{1}{2}$  lb. of oatmeal and a quart of milk daily, costing 5s. 3d. per week, though the average cost of bought food per head is only about 3s. Three pennyworth of oatmeal contains as much nourishment as 3 lb. of meat costing 2s. 6d. A very good vegetarian dinner can be obtained for 4d., containing the same nutrition as a meat dinner for 2s. We must ever remember, however, that of vegetable albumen only 46 per cent. is digested, while of meat albumen 80 per cent. is used.

In Western Europe the diet is one-quarter meat and three-quarters vegetables. The amount of meat eaten per head in England is 136 lb. per annum, in Belgium, 84 lb., in France, 46 lb., in Germany, 35 lb. Most meat is eaten in London.

**Special Diets.** The agricultural labourer lives chiefly on bread, cheese, bacon, potatoes and greens. The artisan adds meat and butter to these.

The best mixed diet to supply 4,500 grs. of carbon and 300 grs. of nitrogen daily is 2 lb. of bread and  $\frac{1}{2}$  lb. of meat, or any food in the proportion of  $3\frac{1}{2}$  parts of non-nitrogenous food to 1 part nitrogenous.

Of nitrogenous food a baby requires 30 grs. per pound of body weight daily—e.g., if its weight be 18 lb., 1,540 grs. or 2 pints of milk will be needed. This decreases down to 15 grs. per pound body weight in old age—e.g., if the weight be 11 stone, 5 oz. is required or 6 pints of milk.

**Analysis of Foodstuffs.** The following analysis of a few leading articles of food will

show how far each constitutes a complete diet in itself.

The true proportion of food is 1 part nitrogenous to  $3\frac{1}{2}$  non-nitrogenous.

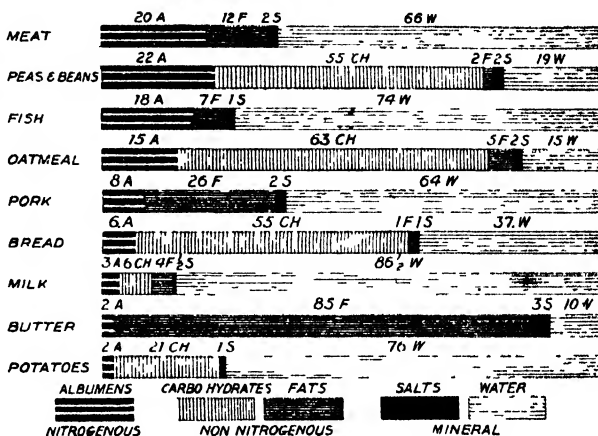

TABLE OF NUTRITIVE VALUE OF FOODS

The table shows that milk and, theoretically, pork both contain the right proportions of the two foods—that is, 1 part nitrogenous to  $3\frac{1}{2}$  parts non-nitrogenous. The large amount of fat which pork contains, however, renders it very hard to digest; and therefore it is practically useless as a complete diet.

Milk is 9 parts water,  $\frac{1}{3}$  albumen,  $\frac{1}{3}$  fat, and  $\frac{1}{3}$  sugar, proportions that are perfect for a complete diet.

Bread, we see, is deficient in nitrogen, as are rice and potatoes to a still greater extent, while fish has the proportions reversed,  $3\frac{1}{2}$  to 1, instead of 1 to  $3\frac{1}{2}$ .

A diet requires, of course, not only to be mixed, but to be varied in quantity according to the amount of work done and waste produced.

**Amount of Daily Food.** It is found that on an average a man requires for his existence, in dry solids, 3 or 4 oz. each of proteids and fats, 10 oz. of carbohydrates, 1 oz. of salts, besides 3 pints of water, or about one twenty-fifth part of his weight daily. If he be working very hard, the quantities may be nearly doubled; if he be at perfect rest, they may be reduced one-third; or, in quiet life the solids amount to 18 oz., in ordinary work to 22 oz., in hard work to 2 lb. The amount required also depends on age, season and climate.

Many attempts have been made to diminish the bulk and weight of food without decreasing its force; but all have practically failed. It appears that the organism requires *bulk*, and the fact that all the food is not digested is by no means an evil.

## OUR TWO SELVES

Human Personality. The Thesis of Frederic Myers. Our "Earthly Manifestation" and Our "Spiritual Self." Genius. Sympathy—the March Word of the Future

By HAROLD BEGBIE

WE would begin this part of our course, which is concerned with the great thesis of Frederic Myers, by a quotation from the epilogue to "Human Personality," wherein he sums up his own conviction concerning the souls of the dead:

**The Larger Self.** "Observation, experiment, inference, have led many inquirers, of whom I am one, to a belief in direct or telepathic intercommunication, not only between the minds of men still on earth, but between minds or spirits still on earth and spirits departed. Such a *discovery* opens the door also to *revelation*. By discovery and by revelation—by observation from without the veil, and by utterance from within—certain theses have been provisionally established with regard to such departed souls as we have been able to encounter. First and chiefly, I at least see ground to believe that their state is one of endless evolution in wisdom and in love. Their loves of earth persist, and most of all those highest loves which seek their outlet in adoration and worship. We do not find, indeed, that support is given by souls in bliss to any special scheme of terrene theology. Thereon they know less than we mortal men have often fancied that we knew. Yet from their step of vantage-ground in the universe, at least, they see that it is good. I do not mean that they know either of an end or of an explanation of evil. Yet evil to them seems less a terrible than a slavish thing. It is embodied in no mighty potentate; rather it forms an isolating madness from which higher spirits strive to free the distorted soul. There needs no chastisement of fire; self-knowledge is man's punishment and his reward; self-knowledge, and the nearness or the aloofness of companion souls. For in that world love is actually self-preservation; the communion of saints not only adorns but constitutes the life everlasting. Nay, from the law of telepathy it follows that the communion is valid for us here and now. Even now the love of souls departed makes answer to our invocations. Even now our loving memory—love is itself a prayer—supports and strengthens those delivered spirits upon their upward way. No wonder; since we are to them but as fellow-travellers shrouded in a mist; 'neither death, nor life, nor height, nor depth, nor any other creature' can bar us from the hearth-fire of the universe, or hide for more than a moment the inconceivable oneness of souls."

**Soul is One.** From this beautiful passage the reader will enter into the spirit of the thesis which we shall presently lay before him. He enters, as it were, through

the poetry and music of the intelligence who speaks to him in human language, into the very holy of holies of that noble soul. The inconceivable oneness of souls is the great chord struck by Frederic Myers on the strings of philosophy. He speaks about the hearth-fire of the universe. At that fire of infinite mercy he sees gathered not only the good and the great, but the poor shivering madman, the hysterical woman, the guilty malefactor, and the debauched and abominable sons of vice. Nothing that we know on the earth is parochial or colonial, but belongs to the vast and infinite universe. He isolates nothing, makes nothing finite. The highest achievements and the most transcendent aspirations of man are the reachings forward into the future of his infinite destiny, and the blackest and most tragical of man's perversions are but the persistencies of a past from which he has emerged only with the utmost travail and agony of soul.

**The Problem of Personality.** And this belief is not a mere echo from the creeds of the past, Buddhism and such-like, but is based on the most careful investigation of Nature's phenomena ever conducted by human mind, and is the fruit of the most catholic philosophy which has ever been presented to intelligent men. Let the student possess himself of those two wonderful volumes "Human Personality" (Longmans) and he will see that the thesis of Frederic Myers is broad based upon the facts of existence and results from an inquiry conducted in the spirit of purest science—an interrogation of Nature entirely dispassionate, patient, and systematic.

The thesis of Frederic Myers is this, that man is one self, but that while his total self or entire ego remains in a spiritual state—that is to say, outside the margin of human consciousness—only a fragment of that self manifests itself above the threshold of consciousness. He speaks not of a dual mind, but of the *subliminal self* (that is to say, the total and spiritually existing self) and the *supraliminal self* (that is to say, the fragmentary and earth-manifesting self).

**Our Earthly and Spiritual Selves.** In other words, I speak of myself as a man and know myself as a man, but there is a far larger spirit from which I am come which is also me. At death, my earthly self—carrying with it all its terrestrial experience—will reunite with the spiritual self; while and during earth-life my supraliminal self can constantly receive comfort and strength from the subliminal self which is always conscious of its needs. On the balance between the subliminal and supraliminal self

depends the problem of personality. Let us take an example.

A man with a large, healthy, and active brain is often a fool, nay, is sometimes a lunatic, while a man with a small and sometimes a partially diseased brain is frequently a genius. The reason is this: In the first case the fragmentary self detached to work the brain is too small or weak to take advantage of its splendid organ, while in the second case the fragment detached is so powerful and vigorous that it is able to bend an inferior machine to great issues. Thus, Beethoven would make finer music from a penny whistle than a savage from the Andaman Islands could draw from a perfect piano.

This theory of a partially but never wholly manifested self is, perhaps, seen with greater clearness in that form of personality which we designate as genius; or perhaps it would be more accurate to say that in his chapter on genius Myers has been happiest in demonstrating the verity of a thesis which he has proved to be equally applicable to every phase of human consciousness.

**What is Genius?** Myers suggests that genius should be regarded as a power of utilising a wider range of faculties, in some degree innate in all, than other men can; a power of appropriating the results of subliminal mentation to subserve the supraliminal stream of thought; so that an "inspiration of genius" will be in truth a *subliminal uprush*, an emergence into the current of ideas which the man is consciously manipulating of other ideas which he has not consciously originated, but which have shaped themselves beyond his will, in profounder regions of his being.

Let us here quote Myers in full:

"Since the germ of life appeared on earth, its history has been a history not only of gradual *self adaptation* to a known environment, but gradual *discovery* of an environment, always there, but unknown. . . .

"It is probable, to begin with, that the only environment which the vast majority of our ancestors knew was simply hot water. For the greater part of the time during which life has existed on earth, it would have been thought chimerical to suggest that we could live in anything else. It was a great day for us when an ancestor crawled up out of the slowly-cooling sea; or, say, rather, when a previously unsuspected capacity for directly breathing air gradually revealed the fact that we had for long been breathing air in the water. . . . May we not, then, suppose that there are yet other environments, other interpretations, which a further awakening of faculty still subliminal is yet fated by its own nascent response to discover? . . . The higher gifts of genius—poetry, the plastic arts, music, philosophy, pure mathematics—all of these are precisely as much in the central stream of evolution,—are perceptions of new truth and powers of new action just as decisively predestined for the race of man—as the aboriginal Australian's faculty for throwing a boomerang or for swimming up a tree for grubs. . . .

**What Does Evolution Mean?** "What inconsistencies, what absurdities," Myers continues, "underlie that assumption that evolution means nothing more than the survival of animals fittest to conquer enemies and overrun the earth! On that bare hypothesis the genus *homo* is impossible to explain. No one really attempts to explain him except in the tacit supposition that Nature somehow intended to evolve intelligence—somehow needed to evolve joy; was not satisfied with such an earth-overrunner as the rabbit, or such an invincible conqueror as the influenza microbe. But *how much* intelligence, *what* kind of joy Nature arrived at—is this to be left to be settled by the instinct of *l'homme sensuel moyen*? or ought we not rather to ask of the best specimens of our race what it is that they live for? whether they labour for the meat that perisheth, or for love and wisdom? . . . it must be on the future as much as on the past, on what is now in process of evolution as much as on what has already been evolved, that the attention of psychologists should be fixed."

From these few extracts the reader will perceive the great drift of Myer's thesis. Genius is not to be regarded as a mere variation from the normal, but an assurance of greater faculty and profounder sensibility within the purposes of future evolution. There is no normal, no abnormal. The race of man is in perpetual flux, and at no single point can you lay a finger and say, "here is the perfect man, the end of things created." As well might a man shoot an arrow at a minute in time and hope thereby to set chiming the clock of eternity. Genius—so far as we are concerned—comes into the world to awaken and disturb placidity and smug content. "I assume in the man," says Myers, "a soul which can draw strength and grace from a spiritual universe, and conversely I assume in the universe a spirit accessible and responsive to the soul of man. . . . that which religions have claimed for their founders or for their saints, psychology must claim for every form of spiritual indrawing, every form of spiritual response; for sleeping vision, for hypnotic rejuvenation, for sensory and motor automatisms, for trance, for ecstasy."

**Our Inheritance from Great Minds.** And then, after declaring that "Childhood is genius without capacity," Myers concludes his chapter on Genius in these words:

"From a greater distance we can watch the inward stir of mighty thought, the same for Eschylus, for Newton, for Virgil—a stir independent of worldly agitation; like the swing and liberation of the tide-wave across the ocean, which takes no note of billow or of storm.

"Nay, we can see against the sun 'the eagle soaring above the tomb of Plato,' and in Paul, as in Plotinus, we can catch that sense of self-fulfilment in self-absorption, of rapture, of deliverance, which the highest minds have bequeathed to us as the heritage of their highest hours.

"These our spiritual ancestors are no eccentrics nor degenerates; they have made for us the

sanest and most fruitful experiment yet made by man; they have endeavoured to exalt the human race in a way in which it can in truth be exalted; they have drawn on forces which exist, and on a soul which answers; they have dwelt on those things 'by dwelling on which it is,' as Plato has it, 'that even God is divine.'

**The Destiny of the Race.** It now only remains for us to reiterate the chief points of this famous thesis, leaving the reader to make himself acquainted with the mass of information supporting the argument through the two volumes of "Human Personality," which should stand on the bookshelves of every student.

The destiny of the race, rather than its past, is to become the science of the future. We know with a sufficient accuracy what we were; it behoves us now to inquire what we shall become. To embrace this reasonable suggestion is to find ourselves driven inwards upon ourselves. What are we? With what faculties are we endowed? To what end is the discontent and unrest of Nature?

Myers has answered these questions. We are men informed with a soul which is fragmentary of a higher self; we can put ourselves into communion with that higher self or we can so concern ourselves with terrestrial occupations as to live wholly unconscious of its existence. The faculties we have used in our struggle with Nature are in the forefront of our consciousness, the tools nearest to our hand; behind these are faculties of another and a higher order waiting to be discovered for use in higher energies of the soul. The unrest in Nature is the effort of the forces of evolution to bring into being ever greater and higher intelligence, intelligence far superior to the merely hedonistic satisfactions of barbarous periods, and conscious of its spiritual destiny.

**Sympathy Leads to Knowledge of God.** The supraliminal self, or, as Mr. Hudson has called it, the objective mind, is to learn in the future the use of other faculties from the subliminal self, or, as Mr. Hudson says, the subjective mind. It will depend more on inspiration, and intuition than on laborious observation and careful deductions; it will enjoy a greater clarity of vision; a fuller, if not a quite perfect, memory; a knowledge of things to be; a depth and intensity of feeling hitherto hardly guessed even by the most beautiful of souls.

The future, according to Myers, is to be growth in this knowledge, a gradual discovery of psychic faculty with a corresponding deepening and widening of the spiritual life. The end to aim at is sympathy. We are to quiet the perturbations of the supraliminal self, to still the desperate anxieties of the carnal mind, and to get into sympathetic communion with the subliminal self which is ready always to sustain and animate us. Sympathy is the march-word of the future. Gradually we are to realise that the universe is our universe, and that sacred beyond all temples and all altars is the inconceivable oneness of souls. Sympathy with man, sympathy with self, is the end knowledge of God.

**Growth in Holiness.** "For souls not yet perfected, but 'still on earth,'" says Myers, "I have foretold a growth in holiness. By this I mean no unreal opposition or forced divorcement of sacred and secular, of flesh and spirit. Rather I define holiness as the joy too high as yet for our enjoyment; the wisdom just beyond our learning; the rapture of love which we still strive to attain. Inevitably, as our link with other spirits strengthens, as the life of the organism pours more fully through the individual cell, we shall feel love more ardent, wider wisdom, higher joy; 'perceiving that this organic unity of soul, which forms the inward aspect of the telepathic law, is in itself the Order of the Cosmos, the Summation of Things. And such devotion may find its flow in no vain self-martyrdom, no cloistered resignation, but rather in such pervading ecstasy as already the elect have known: the vision which dissolves for a moment the corporeal prison-house; 'the flight of the One to the One.'"

In conclusion, we would state that at the foundation of this thesis, above all other discoveries of modern days in which he played so devoted a part, is the law of telepathy. Under the heading of Telepathy the reader will find abundant proof that ideas can be communicated from mind to mind over vast distance of space. It is upon this spiritual sympathy, we say, that Myers has built up the fabric of his thesis concerning human personality, which is destined to stand, side by side with the work of Aristotle and Kant, so long as the earth endures; that man's earth-manifesting spirit is but fragmentary of an ego entirely spiritual, and that the greater the sympathy existing between this twain the greater the man and the surer the hope of eternal happiness.

**The Mysterious Force in Man.** The future of psychology must be along this road. The day is gone when serious men will pay attention to a philosophy which deals with the normal man, and leaves out of count the mysterious aberrations of personality which contradict at a thousand points all the old, comfortable theories of the human race. Whether it will ever be possible to demonstrate the soul we are not concerned to argue; but we protest that psychical science has already amply contradicted the dogmatic utterances of the materialistic school, and this altogether apart from any of those occult investigations which concern the spirits of the dead. In the consulting-room of the properly qualified hypnotist, the student may learn that man is possessed of an intelligence differing in every respect from that by which he is accustomed to guide his action during normal life. Call this intelligence, subjective mind, or eternal spirit, the fact will remain that there is in man some force or principle which has hitherto escaped the attention of empirical psychology and dogmatic materialism; and, further, it will be seen that this mysterious force or principle is not beyond the examination of science, but rather lends itself easily to investigation in the condition which we speak of as hypnotic trance.

# CARPENTRY

The Tools and Appliances Used by the Carpenter. Sawing, Planing, Chipping, and Boring Tools. Non-cutting Tools

Group 4  
BUILDING

24

Continued from  
page 3248

By WILLIAM HORNER

WE shall first consider briefly the hand tools and appliances used in carpentry, illustrations being given of a number of those most commonly used; and later on, when sawing, planing, and other processes are specially dealt with, the tools concerned in those operations will be reviewed in greater detail. In the Joinery and Cabinet-making sections, which are to follow Carpentry, tools will be described and illustrated where desirable. Most of the tools used in carpentry are used in joinery and in cabinet-making also. The difference between the trades necessitates some special tools for each, but carpentry is the more elementary trade and the one that requires the fewest number. Some tools, such as the two-handled cross cut saw and the adze, used only for large and heavy work, may be regarded as exclusively carpenter's tools, but a set of the common woodworking tools contains nothing that is not useful and generally necessary in any woodworking trade.

**The Carpenter's Bench.** The bench on which the work is done is an appliance rather than a tool. Benches vary in dimensions and in details. The carpenter's bench is generally 3 in. or 4 in. lower in height than those used for smaller and more delicate work. This is because large and heavy work can be more conveniently handled on a low bench, and partly also because the shorter the legs the stouter it will be. The height of a bench is about that of an ordinary kitchen table, but it should be decided entirely by what the man who works at it finds most convenient. This will depend on his own height and on the class of work he does. Strength and rigidity are essential, and therefore the legs are always connected near their base by rails. For the same reason it is desirable to have flaps of considerable depth screwed to the sides. A stop for planing against is necessary, and also a vice for gripping wood. These are both situated near the left-hand end of the bench, as shown in 1. By slightly increasing the width of the single bench, and fitting a stop and vice to the opposite corner it may be converted into a double bench at which a man may work on each side; but generally it is more convenient to have the far side against a wall, preferably with a window opposite. Fixed to a wall the bench is more steady, and shelves and racks for tools can be fitted up. Single benches are seldom made more than 2 ft. 6 in. in width; but lengths vary greatly. When they exceed 10 ft. or 12 ft. it is best to have length enough for two benches, and to fit an intermediate vice and stop.

**Varieties of Saws.** The first and most essential tool for operating on wood is a saw. In saw mills and well-equipped shops, machine saws, either of the band or circular type, do nearly all the sawing, and only a little is done by hand; but the purpose here is to deal only with hand tools and methods, and, therefore, the ordinary hand saw [2] is of the first importance. The average length of this is about 26 in., and the number of teeth to the inch depends on the work for which it is chiefly intended. Most carpenters possess two of these saws, one for *ripping* or cutting with the grain, and one for *cross-cutting*. The former is known as a *rip* saw, and the latter is really the *hand* saw proper. Another saw, known as the *half rip*, is used for ripping where the teeth of the rip saw would be too coarse. For general purposes the ordinary hand saw, intended primarily for cross-cutting, is the most useful. The tenon saw [3] comes next in importance. This is used for finer work on the bench. The bow saw is employed for cutting to curved outlines, and so also are two rather simpler types of saw, known as the *keyhole* saw, and the *compass* saw. The *panel* saw is a small type of hand saw, and the *dovetail* saw is a small type of tenon saw. Cross-cut saws of large size for cross-cutting logs generally have a handle at each end, so that two men can work them. Another very large saw worked by two men and used for ripping is called a *pit* saw. Its lower end works in a pit over which the piece of timber extends. Its teeth are given a great deal more rake than any other saw for hand use.

**Planes.** After the saw the next tool which comes into most frequent use is the *plane*. Here, again, machinery does the bulk of the work in commerce, though not quite to such an extent as in sawing. The *jack* plane [4] is used for removing the rough surface, and for quickly reducing to thickness. The *trying* plane [5] is employed for producing true surfaces. The *smoothing* plane [6] is used for smoothing and cleaning a surface where accuracy is of secondary importance. These three planes are used on any surfaces where they can be employed, but there are a great number of other planes for special purposes. The *jointer* is an extra long trying plane for making long joints. The *rebate* is a narrow plane for rebates, and the *fillister* is a slightly different plane for the same kind of work. The *plough* is used for grooves. *Hollows* and *rounds* are required for planing hollow and rounding surfaces of narrow width, and *moulding* planes are for mouldings. *Metal* planes are made in great variety for small work. *Matching* planes are used for making matched

## BUILDING

joints. *Routers* are for clearing out recesses to a uniform depth.

**Chisels and Gouges.** Chisels and gouges are an important class of cutting tools, coming next to planes. Chisels are of three main types—the *firmer* chisel [7], the *mortise* chisel [8], and the *paring* chisel. The *firmer* chisel is used for general work, with or without a mallet. The *mortise* chisel is employed with a mallet for mortises and heavy work. The *paring* chisel is long and thin, and is used for paring, and will not stand heavy malleting and prising. Gouges are of two main types—the *outside* or *firmer* gouge [9], and the *inside* gouge [10], generally used for paring. The terms *outside* and *inside* denote the side on which the bevel of the gouge is ground. Gouges vary in curve as well as in width.

**Boring Tools.** Tools for boring holes are always necessary at an early stage in any wood-work construction. Bits, used in a brace [11] or in a machine, are employed in most cases. The most important of these is the *centre* bit, so called because it has a point which can be made to enter the wood exactly where the centre of the hole is to be. The *twist* or *auger* bit shown in 12 is a centre bit, but it is not called by that name because the name has been given to an older form. These bits range in diameter from about  $\frac{1}{4}$  in. to  $1\frac{1}{2}$  in., the medium sizes being those most used. The carpenter also employs them in the form of *augers*. That is, instead of having a shank to fit the brace, they are greatly increased in length and are fitted with a handle like a very large gimlet. This form gives more power in turning and enables the tool to bore or to reach a longer distance, but of course it cannot be turned so quickly as in a brace. The older form of centre bit is still commonly used; but it is so inferior to the twist bit in every way that it will probably ultimately become obsolete. Small bits for screw holes are generally of the shell type [13]. There is considerable variety in the braces that are used for operating the bits. Formerly, wood braces were very popular in England, though more expensive and not more efficient than iron ones; but the iron brace is made in more variety now, and the ratchet movement which is generally fitted to it is very useful. *Gimlets* and *bradaws* are boring tools for use in the hand. Gimlets [14] are employed for boring screw holes when it is not convenient to use a brace and bit. Bradaws [15] are so small that they are more efficient fitted with a handle of their own than a bit of the same diameter used in a brace could be. The countersink bit [16] is used for countersinking screw holes, and the screwdriver bit [17] is used in the brace for turning screws.

**Other Cutting Tools.** Besides those already mentioned there are some other cutting tools which may be considered not quite so essential. There is the *spokeshave* [18], which is really a form of plane. There is the *adze* and *axe*. The hatchet or axe is used for splitting and chipping, and is too well

known to need any description. The adze differs from the hatchet only in having its cutting edge at right angles like a hoe, and being provided with a longer handle than a hatchet so that it can be used for chipping the surface of a piece of wood lying on the floor. The *draw knife* [19] is another tool which is used for trimming and removing chips, generally from the corners or edges of wood. It is a knife fitted with a handle at each end, and it cuts, not by hacking, but by being drawn through the wood by means of the handles.

**Non-cutting Tools.** After the cutting tools come the tools and appliances for testing, holding, marking out, measuring, etc. For testing the accuracy of work, *squares* [20], *straight-edges*, *winding strips*, *bevels* [21], *calipers*, *spirit levels*, and *templates* are used. For holding and assisting in operations there are a number of special appliances used by carpenters and other woodworkers, most of which, being entirely of wood, are made by the workman himself. The *shooting board* is used for planing wood on. Its primary purpose is for planing edges in place of holding the wood in the vice. It affords a guide for the plane, and ensures an approximately square edge without constant testing with a square. It avoids injury to the surface of soft wood, which sometimes occurs through tight gripping in a faulty vice, and in the case of very thin pieces of wood there is some risk when held in the vice of their breaking under the weight of the plane. The shooting board is also very useful for doing fine work on when the bench surface near the stop is in a badly worn condition. The *mitre block* and *mitre box* are used as guides for the tenon saw in sawing to definite angles. The *bench hook* is a block of wood employed on the bench as a stop for sawing against. The *angle board* is a board about the same size as a shooting board, with V grooves along its surface and a stop at the end. Strips of wood can be laid corner down in one of these grooves and can then be planed to a triangular section. *Hand screws* and *clamps* of various kinds are used for holding pieces of wood together temporarily while glue is setting, or while screwing, nailing, or marking out. *Saw stools* are low heavy stools for sawing on. *Trestles* are a lighter and higher form of stool, generally used in pairs for laying work on.

**Gauges.** Gauges are constantly required in woodwork at the bench, for marking lines for cutting to. They consist of a block or guide which can be adjusted on a stem to a given distance from the cutter which marks the line. The guide is slid against a face or edge of the wood which is already planed true, and the marker, or nicker, cuts a parallel line slightly into the surface. This is more suitable than a pencil line for working to. An ordinary gauge is shown in 22. *Mortise gauges* [23] have two markers adjustable in relation to each other, and two parallel lines can thus be marked simultaneously. These gauges are about 6 in. or 8 in. in length, which is long enough for ordinary

Shell Bit. 14. Gimlet. 15. Countersink Bit. 16. Screwdriver Bit. 17. Screwdriver Bit. 18. Spokeshave. 19. Draw Knife. 20. Try Square. 21. Bevel. 22. Ordinary Gauge. 23. Mortise Gauge. 24. Panel Gauge.

## BUILDING

work. *Panel gauges* [24] are 20 in. or more in length. *Dividers* [25] and *trammels* [26] are used for marking circles and sweeps and for making equal divisions.

**Other Hand Tools.** Hammers of various sizes are employed, chiefly for driving nails and brads. The *claw hammer* [27] is generally preferred by carpenters because the claw can be used for withdrawing nails. *Mallets* are used for driving chisels and gouges when the work is rather too heavy for pressure with the hands alone. A mallet is preferable to a hammer for this purpose, because its effect is not so intense and local. It imparts more of a pushing action throughout the chisel than a hammer does. A hammer exerting only the same power soon batters the end of the chisel handle to pieces.

The *trimmer* is a machine which is very useful on any woodworker's bench. It saves a great deal of chiselling, sawing, planing, and testing with square and bevel. It is a shearing machine operated by a lever. The *bar cramp* [30], of which there are several varieties, and the *hand-screw* [31], are used for cramping parts together temporarily. *Saw-stools* [32] are used for sawing on.

**The Function of Cutting Tools.** All cutting tools, whether of the saw, chisel, plane, or scraper type, remove the material in practically the same way. The sharp edge of the cutter enters the surface and cuts and lifts away a shaving. The teeth of a saw act in the same way as a plane iron, the only difference being that the teeth of the saw are very narrow

### CARPENTERS' TOOLS

25. Compasses or Dividers. 26. Trammels. 27. Claw Hammer. 28. Pincers. 29. Screwdriver. 30. Bar Cramp.  
31. Hand-screw. 32. Saw-stool.

and the smaller and lighter the hammer the worse are its effects. *Punches* are used for driving nails below the surface. *Pincers* [28] are for withdrawing nails, and for any other purposes for which they happen to be suitable. *Chalk lines* are used for marking long straight lines for sawing to. These are often required on planks, especially when the edges are not straight enough for gauging from. *Screwdrivers* [29] are used for turning screws.

**Sharpening Tools.** *Grindstones* and *hones* are used for sharpening tools. *Hones* or *oil-stones* are mounted in a wood case to minimise the risk of breakage and to protect them from dirt and prevent them from slipping when in use. *Slips* are small pieces of oilstone held in the hand for sharpening the cutting edges of gouges.

and cut a groove through the wood. The difference between planes and chisels is that a plane iron is fixed to cut to a certain depth, while a chisel is controlled solely by the hand. Planes are used primarily for levelling and smoothing surfaces, chisels primarily for removing material; but each is employed generally on surfaces for which the other would not be suitable. The scraper is a tool which is generally used after the plane on hard wood. It is used more by cabinet-makers than by carpenters. It is a thin plate of steel used to scrape out plane marks and obtain a smooth surface in places where the grain is too curly to be planed without getting torn up. Its edges are made acute by burring them slightly. When properly sharpened it scrapes a very fine shaving.

FOR A SHORT DICTIONARY OF TERMS IN CARPENTRY, see following pages

# A SHORT DICTIONARY OF CARPENTRY & CABINET WORK

**ADZE**—A long-handled tool of the axe type used in heavy carpentry for dressing large pieces of timber. It differs from an axe in several details, but the most noticeable is that the blade is at right angles instead of in line with the handle.

**Angle Board**—A board with V grooves in which to plane angles, fillets, round rods, etc.

**Astragal**—A semicircular moulding which projects. When flush with the surface it is a *bead*.

**Auger**—A long boring tool, usually fitted with a transverse handle like a large gimlet.

**Auger Bit**—A bit of the auger type used in a brace or machine.

**Axe**—Used for felling trees and chipping and splitting wood. When small and light it is called a *hatchet*.

**BACK SAW**—A saw stiffened by a metal back. Tenon and dovetail saws are examples.

**Badger Plane**—A large rebate plane.

**Balk**—A squared trunk or log.

**Bar Clamp**—A clamp the body of which is a bar on which the loose jaw slides.

**Barfaced Tenon**—A tenon shouldered only on one side and flush on the other.

**Batten**—A piece of wood screwed or nailed on a surface to give strength, usually to stiffen cross grain or hold boards together.

**Baywood**—An inferior species of mahogany.

**Bead**—A small rounded moulding with a quirk on one or both sides.

**Bead Plane**—A plane with its sole and cutting edge of a form for planing beads.

**Beam**—A long piece of timber of large section, generally used in a horizontal position for spanning, and supporting weights.

**Beaumontagne**—A stopping composed chiefly of resin and beeswax used for filling holes and defects in cabinet work.

**Bench**—The table on which woodwork is done. It is provided with a vice and stop.

**Bench Hook**—A block of wood which fits against the edge of the bench, and is used as a stop for cross-cutting pieces of wood on the bench.

**Bench Knife**—An appliance sometimes used for holding wood while planing.

**Bench Planes**—The planes constantly used and kept on the bench. Generally understood to mean the jack, trying, and smoothing planes.

**Bench Screw**—The name sometimes applied to the vice used for gripping wood at the bench.

**Bevel**—An adjustable instrument used for testing angles. Angles themselves are also called *bevels* when they are not square.

**Birdsmouth**—An angle notched out of the end of a piece of timber to enable it to fit on to the angle of another piece.

**Bit**—Generally a boring tool for use in a brace, but the term includes all cutting tools not permanently attached to their handles.

**Block Planes**—Small metal planes, generally with the bevel of the cutting edge upwards and the iron lying at a low angle.

**Bolection Moulding**—Moulding which stands above a surface and fits over an edge.

**Bolt**—Bolts for wood generally have square nuts and rounded heads, and a square body extending an inch or so from the head to prevent the bolt from turning.

**Bow Saw**—Also called *frame saw*, or *turning saw*. A narrow saw fitted in a frame which keeps it from bending.

**Box Tenon**—A tenon sometimes used on the ends of corner posts to fit the mortises of two rails which meet there at right or other angles.

**Brace**—The appliance used for operating boring bits. Also the term used to signify a strut or bar of any kind for increasing the rigidity of a frame or other structure.

**Brad**—A variety of small nail, less frequently used than formerly.

**Bradawl**—The tool used for making very small holes in wood.

**Breaking Joint**—Arranging end grain joints in alternate positions, as in segment work.

**Bridge Joint**—A form of joint in which the end of one member fits over a tongue cut in the body of the other.

**Buckle**—A saw blade out of truth through being in an unequal state of tension is said to be *buckled*.

**Buhl Work**—Inlaying with other materials than wood.

**Bull-nose Plane**—A small metal plane in which the portion of the sole in front of the iron is connected with the body of the plane by being arched over the mouth, and the shavings have to escape at either side.

**Butt Hinges**—The common type of hinge with square edges intended for shanking into the surface of the wood.

**Butt Joint**—A joint in which the two connected parts merely abut against each other.

**CALLIPERS**—An instrument with adjustable arms used chiefly for measuring diameters of circular work where a rule cannot be used.

**Camber**—The amount of arch given to a horizontal beam to counteract the effect of sagging.

**Carcase**—The main body of a structure without its minor fittings.

**Caul**—The piece of metal or wood used for maintaining even pressure on veneer until the glue has set.

**Centering, or Centre**—The temporary wood structure necessary for building brick, stone, or concrete arches on.

**Centre-bit**—A bit with a central point which projects into the wood and assists in starting and keeping the bit on the centre required.

**Chalk Line**—A reel of fine cord used for marking straight chalk lines on surfaces.

**Chamfer**—The bevelling off of square corners. The term is applied both to the operation of chamfering and to the angle or chamfer itself.

**Charlot Plane**—A small metal plane with wood wedge and deeper front than a block plane.

**Chase Mortise**—A mortise made long enough to permit the insertion of a member which cannot be put directly in from the front. The extra length is afterwards filled up.

**Check**—Another name for a rebate or shoulder.

**Chisel**—A long, narrow, flat cutting tool sharpened at its end.

**Chuck**—A lathe accessory for securing work to the mandrel.

**Circular Saw**—A machine saw in the form of a circular plate.

**Clamp, or Cramp**—An appliance for holding parts together by pressure. Also the act of clamping.

**Cleaving**—Timbering of a shaft, mine, or cylinder.

**Cleat**—A wood clamp which, in addition to squeezing together, keeps a surface from warping. The term is also often used in the same sense as battens, but generally means a solid attachment to which some other part can be connected.

**Clinch, or Clench**—The bending over of the protruding point of a nail.

**Coach Screw**—A large screw for wood provided with a square head on which a spanner is used.

**Cofferdam**—A watertight enclosure of piles and boarding under water. It is a temporary construction to facilitate the laying of foundations and supports for bridges and piers.

**Compasses**—Instruments used for dividing and for describing circles and curves up to about 8 in. radius. They are of metal, and generally provided with a wing and pinching screw.

**Compass Saw**—A saw for cutting sweeps. It resembles a keyhole saw, except that it is larger, and has a handle of the tenon saw type.

**Cornice**—The top horizontal moulding of any structure.

**Countersink**—To sink the head of a screw flush with or below the surface. Also the name of a bit for enlarging the hole for the purpose.

**Cramp**—See *clamp*.

**Cross-cut Saw**—A saw intended for cutting across grain. Unless otherwise specified, a large two-handed saw is meant.

**Cup Chuck, or Bell Chuck**—A lathe chuck bearing and resemblance to a cup or bell. Short lengths of wood are chucked by having an end driven tightly into it.

**DEAL**—The various kinds of pine are commonly called deal. Also, 3-in. boards 9 or 10 in. wide.

**Dividers**—Small compasses used either for dividing or for striking circles.

**Dog**—A staple used for temporarily holding pieces of wood together, generally while glue is setting.

**Double Tenon**—Two tenons running side by side in separate planes.

**Dovetail**—A form of interlocking joint often employed when ends of wood meet at right angles.

**Dovetail Saw**—A fine saw for cutting dovetails.

**Dowels**—Hardwood pins used in edge joints and for numerous other purposes.

**Draw Bore Pin**—A metal pin used for drawing mortise and tenon joints together.

**Drawer Lock Chisel**—A bent chisel for working in confined situations.

**Draw Knife**—A large knife with a handle at each end.

**Dress**—To plane the surface of a piece of wood true is to dress it.

**Dry Rot**—A disease of timber generally brought about by want of ventilation and dampness.

**ELEVATION**—In a drawing, the front view of an object. If specified as side elevation, end elevation, or sectional elevation, the points of view vary accordingly, but they are always taken in a vertical plane with the object standing in its normal position.

**End Grain**—A face of a piece of wood which exposes the ends of the fibres.

**Expansion Bit, or Extension Bit**—A bit which can be adjusted to bore holes of different diameters.

**FACE MARK**—A mark put on one face of a piece of wood to indicate its intended position, or that it has been planed true.

## DICTIONARY OF CARPENTRY

**Face Plate**—The flat plate chuck of a lathe.

**Fanlight**—A sash over a door or window.

**Fence**—The guide used on saw tables, jointing, and other machines.

**Fillet**—Plain hollowed moulding occupying interior angles.

**Fillister**—A rebate plane provided with a guide.

**Finish**—The cleaning up, smoothing, varnishing, and polishing operations thus following the actual construction of anything.

**Firmer Gouges and Chisels**—Are those used for ordinary work. In stoutness they come midway between paring and mortise tools.

**Fished Joint**—A butt joint held together by fish-plates.

**Float**—A file with extremely coarse teeth cut on one face.

**Flush**—Contiguous surfaces that are level with each other or on the same plane.

**Flutes**—A number of hollow fillets side by side, generally round a column.

**Fork Centre**—The pronged chuck of a lathe.

**Fox Wedging**—A stub mortise and tenon joint in which wedges are inserted in the act of driving in.

**French Polish**—Shellac varnish applied with a rubber.

**Fret Saw**—An extremely narrow saw with fine teeth used for sawing ornamental designs in thin wood.

**GAUGE**—Used for marking lines on a surface parallel with one of the edges.

**Getting Out**—To get out wood is to saw out and prepare ready for putting together the pieces required for a job.

**Gimlet**—A small boring tool with screw point and a transverse handle.

**Glasspaper**—Paper coated with powdered glass or flint. Also called *Sandpaper*.

**Glue**—An animal substance used to cement pieces of wood together.

**Glue Pot**—The receptacle in which glue is melted for use. It consists of an inner pot for the glue and an outer one for war.

**Gouge**—A gouge differs from a chisel in being curved in cross section instead of flat.

**Grain**—The fibres of wood are collectively called the *grain*, and the direction in which they run is called the *direction of the grain*.

**Grindstone**—A revolving stone for removing material from cutting tools preparatory to sharpening them on a stone of finer grain.

**Gullet**—In large circular and some other saws there is some amount of space between the bases of the teeth, and this is known as the *gullet*.

**HALF LAP JOINT**—Also *halved joint*, or *lap joint*. A lap joint in which half the thickness of each piece is cut away so that the combined thickness at the joint is no more than that of each single piece.

**Half Rip Saw**—A saw used for ripping, but which has smaller teeth than a regular rip saw.

**Hand Saw**—A saw intended primarily for cross-cutting, but used for general purposes. It has smaller teeth than saws for ripping.

**Hand Screw**—A wooden clamp consisting of two jaws operated by two long screws with handles at their ends.

**Hardwood**—The wood obtained from the broad-leaved varieties of trees.

**Hatchet**—See *axe*.

**Haunched Tenon**—A tenon reduced in width either for a portion or the whole of its length. Employed when there is an objection to cutting a full-width mortise.

**Heading Jolt**—A butt joint between two lengths of timber whose ends meet on a joint.

**Headstock**—The part of a lathe carrying the mandrel which imparts rotary movement to the work.

**Herringbone Strutting**—The short crossed stays between floor joists.

**Hinge**—The means of attachment which permits doors and box covers to swing or fold.

**Holdfast**—An appliance used for holding work down on the bench.

**Holding Up**—Being large enough to flush to required dimensions.

**Hollow Plane**—A plane with rounded sole for planing hollows.

**Hone**—Also *oilstone*. A stone used for sharpening cutting tools.

**Housing**—A structure which encloses something. A joint in which the end of one member is enclosed in the other without being reduced to a tenon.

**INLAY**—Ornamental designs of a material let into the surface of another material.

**Iron**—The cutter of a plane or of any tool or machine in which it is detachable.

**JACK PLANE**—The plane used for roughing down a surface approximately true.

**Jointer**—A small planing machine which cannot be set to plane to a thickness. Also a hand plane of greater length than the tryling plane.

**Joists**—The timbers on which flooring boards are laid.

**KERF**—The cut or space a saw makes in passing through wood.

**Key**—A term with several applications, but its general meaning is a small piece of wood inserted in joints to hold them together or across grain to prevent curvature.

**Keyhole Saw**—Also *pad saw*. A small saw suitable for cutting keyholes or curves.

**King Post**—The main central post of a truss.

**Knot**—A hard spot of timber due to a change in the fibres caused by a branch of the tree springing from there.

**LAGS**—Strips used for building up cylindrical bodies and boarding over ribs of centring. Also called *lagging or staves*.

**Lathe**—The machine used for wood-turning.

**Ledged Door**—A rough door formed of boards held together by battens or ledges.

**Level**—An appliance used for testing the horizontal accuracy of surfaces. Also called a *spirit level*.

**Lintel**—The beam which supports the brickwork or masonry over an opening in a wall.

**Lock Corners**—A term applied chiefly to the corners of boxes made by machinery. They differ from dovetails in being parallel.

**Long Tooth Gauge**—A gauge used for marking lines on surfaces at a different level to the edge which guides the stock.

**MALLET**—A large-headed wood hammer used chiefly for driving chisels and gouges.

**Mansard Roof**—A roof with two different slopes. Also called *curb roof*.

**Marking Out**—Drawing either on a board or on the material itself the size and shape of anything that is to be made. Also called *laying out* or *setting out*.

**Matchboards**—Boards with a groove in one edge and a tongue on the other, so that a number of them will fit edge to edge.

**Mitre**—An angle joint between two pieces meeting at right angles, as in picture-frames.

**Mitre Clamp**—A clamp for holding mitre joints together temporarily.

**Mitre Dovetails**—Secret dovetails cut in a mitre joint.

**Mitre Shooting Board**—A shooting board for planing mitres.

**Mitre Block**—A block with saw cut or grooves to guide the saw in cutting mitres.

**Mitre Box**—A box open at the top and ends and having saw cuts in the sides to guide the saw in cutting pieces laid in the box.

**Mortise**—The slot or recess which receives a tenon.

**Mortise Chisel**—A very stout form of chisel used for mortises.

**Mortise Gauge**—A gauge with two marking points adjustable in relation to each other.

**Muntins**—The vertical dividing bars in a window, door, or other frame.

**NEEDLES**—Supports for scaffolding inserted in walls.

**Needle Points**—A kind of needle without an eye used in cabinet work in place of fine nails.

**Newels**—The main posts which support the handrails of stairs.

**Ogee**—A moulding consisting of a concave and convex sweep dying into each other.

**Oilstone**—The stone used for sharpening tools. So called because it is used with oil on its surface.

**Ovolo**—A round moulding of about a quarter of a circle, but sometimes elliptic in form.

**PAD SAW**—A narrow saw held by pinching screws in a slotted handle long enough to enclose the saw when not in use. Also called *keyhole saw*.

**Pair of Tenons**—Tenons in line with each other. Not the same as double tenons.

**Panel**—A sheet of thin wood used for filling the open area in a frame.

**Panel Gauge**—A gauge long enough to scribe about 18 in. or 2 ft.

**Panel Saw**—A small type of hand saw used for light work on the bench.

**Paring Tools**—Long, thin gouges and chisels intended for paring without the use of a mallet.

**Parquetry**—Flooring made by laying hardwood blocks in various geometrical patterns.

**Piles**—Large wood posts driven into the ground.

**Pincers**—A gripping tool for withdrawing nails.

**Pinned Joint**—A joint in which pins or pegs are driven through to assist in holding the parts together.

**Pitch**—The inclination of a roof or stairway. It is known as *high* or *low* pitch according to the degree of slope. Also the height of an arch.

**Plan**—A view looking down on top of an object.

**Plane**—A cutter carried in some form of block which compels it to cut a thin uniform shaving.

**Plane Iron**—The cutter of a plane.

**Pliers**—Narrow-jawed pincers of various kinds employed for bending wire and for numerous other purposes.

**Plough**—A plane for cutting the grooves for panels and tongued joints.

**Plumb**—Being in line vertically.

**Plumb Bob**—A weighted string, sometimes in connection with a straight-edge, used for testing the vertical accuracy of work. Also called a *plumb line*.

**Poppet**—The adjustable back centre of a lathe. Also called *tailstock*.

**Punch**—A steel pin used in driving nails below the surface.

**Purlins**—Members which unite the trusses of roofs in longitudinal directions.

**QUARTERING**—The bars or strips produced by ripping deals into four pieces.

**Queen Post**—Distinguished from king post chiefly by not being in the central position under a roof.

**Quirk**—The narrow groove or furrow at the side of a bead.

**RAFTERS**—The timbers to which the covering of a roof is attached.

**Rail**—A horizontal bar.

**Raised Panel**—A panel reduced in thickness at its edges.

**Rasp**—A species of coarse file used for wood.

**Ratchet Brace**—A brace with an arrangement which permits it to be worked in an arc of a circle and at the same time to turn the bit only in the forward direction.

**Rebate**—Or *rabbit*—A shallow channel or wide groove or recess planed in a surface.

**Rebate Plane**—A plane whose sole is no wider than the iron.

**Rest**—The arrangement on which the tool rests in a lathe.

**Riff**—A small double-ended bent file or rasp.

**Rip Saw**—A saw with large teeth, intended for cutting in the direction of the grain.

**Round Nose**—A chisel used for scraping hollows in turned work in the lathe.

**Round Plane**—The reverse of a *hollow plane*.

**Router**—A small plane in which the iron may be set to cut to a certain depth below the sole. It is used for clearing out small recesses to a definite depth.

**Rubber**—The piece of cork or wood on which glasspaper is generally wrapped when in use.

**SAG**—The sinking of the middle part of a piece of timber which is supported at its ends.

**Sand paper**—See *glasspaper*.

**Sash**—A frame in which panes of glass are fitted.

**Sash Bars**—The dividing bars which separate panes of glass in a sash.

**Sash Door**—A door with glass in its upper part.

**Sash Plane**—A plane to suit the mouldings of sash bars.

**Saw Set**—Any appliance used for setting or bending the teeth of saws sideways.

**Saw Stool**—A low heavy trestle used for resting planks on when sawing.

**Scaffold**—The temporary wood structure necessary in erecting buildings.

**Scantling**—A term used to signify the width of a piece of timber. It also means pieces of irregular width and thickness.

**Scarf Joint**—A lap joint used for joining two pieces of timber end to end to make one long piece.

**Scotia**—A concave moulding which increases in radius in its lower part. Also called *trochilus*.

**Scraper**—A small piece of sheet steel used for scraping the surfaces of hard wood smooth.

**Screws**—The threaded metal pins used for holding woodwork together. Also called *wood screws* or *screw nails*.

**Screwdriver**—A tool which fits the slots of screw heads, and is used for turning them. Also called a *turn-screw*.

**Screwdriver Bit**—A brace bit used for turning screws.

**Scriber**—A steel instrument for inscribing lines on wood. Also called *striking knife*.

**Seasoned Timber**—Timber from which the sap has been dried out.

**Segments**—Short sweeps used for building up circles or portions of circles.

**Set**—The set of a saw is the amount to which the teeth are alternately bent to opposite sides.

**Set Square**—A triangular square used for testing interior angles.

**Shake**—A longitudinal crack in timber.

**Shank**—The portion of a tool which connects with the handle, or fits the socket of a brace or machine.

**Shell Bit**—A bit used for screw holes. Its body is a channel of crescent-shaped section, and is sharpened at the end.

**Shooting**—Planing the edge of a piece of wood straight.

**Shooting Board**—A board for planing pieces of wood on.

**Short Grain**—When the distance across the grain is greater than the longitudinal dimension, the grain may be said to be *short*.

**Shoulder**—A step, or change of level in a surface, for another part to bear against.

**Side Chisel**—A chisel used at the lathe for parting, and numerous other purposes. Also called *side tool* or *turning chisel*.

**Single Iron**—A plane iron used without a back iron.

**Skew**—Anything set obliquely or at an angle to something else. In skew-mouthed planes, the cutting edge is out of square with the body of the plane.

**Skew Nailed**—Nails driven in at an angle at the feet of posts, and in similar circumstances. Also called *tee nailed* or *tusk nailed*.

**Slip**—A small piece of oilstone used in the hand.

**Slip, or Slot Mortise**—A mortise that is open at the end of the wood as well as going through from one face to the other.

**Smoothing Plane**—A short plane used for smoothing surfaces.

**Socket Chisels and Gouges**—Stout chisels and gouges formed into a socket at the shank end into which the wood handle is driven.

**Sole, or Sole Piece**—The piece of wood used as a base on which to rest the ends of posts or uprights.

**Splice Joint**—A *scarf joint*.

**Spokeshave**—A tool consisting of a knife set in a body or guide, provided with a handle at each end.

**Sprigs**—Small nails with very small heads.

**Spring Dividers**—Dividers which spring open as the wing nut is run back, and keep to the largest extension the position of the nut permits.

**Staple**—A piece of U-shaped iron, with pointed ends. A modified form for holding joints is called a *dog*.

**Stile**—The vertical side pieces of a door or other frame.

**Stop**—The block or catch near the front end of a bench against which the work pieces when being planed. Also the shoulder which stops a door or drawer.

**Stop Chamfer**—A chamfer which finishes short of the extreme point it could be carried to.

**Stopping**—Any plastic material used for filling small holes in order to make an unbroken surface.

**Straightedge**—A long piece of wood or other material with a perfectly straight edge, used for testing the accuracy of flat surfaces.

**Strap**—A bar of iron of rectangular section used for binding timbers together at their joints.

**Strut**—A stay, brace, bar, or support in compression in a diagonal position.

**Stub Tenon**—A short tenon which does not go through the part into which it fits.

**Studs, or Studding**—The vertical bars in lath and plaster partitions.

**Stuff**—A common shop term for timber.

**Stump Tenon**—A tenon made thick for a short distance from its root and thin the remainder of its length. The term is also used for *stub tenon*.

**Sweep**—The term is applicable to almost all curved portions of work, or pieces of wood, when the radius is not very small.

**TANG**—The pointed shank of a tool which is driven into the wood handle.

**Templet, or Template**—A pattern, generally in the form of a thin sheet of material, from which the shape of the actual work is marked or tested.

**Tenon**—The shouldered down end of a piece of wood which fits into the mortise or socket of another piece.

**Thumb Plane**—A very small plane of the smoothing plane type.

**Toe Nailed**—See *skew nailed*.

**Tongue**—A projecting ridge which fits into a groove in an adjoining piece.

**Toothing Plane**—A plane with a serrated iron, used in preparing surfaces for veneer.

**Torus**—A large bead with a fillet.

**Trammels**—An instrument for marking circles and curves of larger radius than ordinary compasses.

**Trestles**—Light supports consisting of four spreading legs and a narrow top, used for resting planks or work on.

**Trimmer**—A shearing machine for wood. Also a beam supporting the ends of joists.

**Trochilus**—See *scotia*.

**True**—Surfaces that are straight, level, or accurately formed to the shape required, or square, or concentric with each other, are said to be *true*. When not so, they are out of truth.

**Truss**—The stiffening of a horizontal beam by braces, which convert it into a rigid angular frame.

**Trying Plane**—A large plane which generally follows the jack plane for finishing and making surfaces true.

**Try Square**—An ordinary square, consisting of a stock and blade, used for testing the accuracy of work.

**Turning Chisel**—See *side chisel*.

**Turnscrew**—See *screwdriver*.

**Tusk Nailed**—See *skew nailed*.

**Tusk Tenon**—A tenon with a stump or tusk at the root.

**Twist Bit**—A bit with a spiral body.

**UNDERCUT**—A shoulder or similar part which overhangs, or has more cut away from its base than from its upper part.

**VARNISH**—A resin or gum dissolved in a suitable liquid.

**Veneer**—Very thin fancy wood glued on to the surface of an article constructed of cheaper wood.

**Veneering Hammer**—A hammer with a very wide edge, used squeeze fashion on veneer, instead of using cauls.

**Vise, or Vise**—An appliance attached to the bench and used for gripping.

**WARPING**—The twisting or springing of wood caused by unequal shrinkage. The term generally means an actual twist or wind, but sometimes is used when only curvature is meant.

**Whet**—To sharpen a tool on a hone.

**Winding**—The twist, or east, or wind that sometimes develops in large pieces of wood.

**Winding Strips**—Parallel strips used for detecting the amount of twist in the surface of long pieces of wood.

**Wing Compasses**—Compasses with an arm and pinching screw for holding the legs at a fixed distance apart.

**Wire Nails**—Nails made with parallel bodies in great variety, and now the most commonly used kind of nail.

**Wood Screw**—The kind of screw commonly used for woodwork.

# THE MODERN BAKERY

Commercial Breadmaking. Names and Varieties of Loaves.  
Yeast Foods. Milk and Brown Bread. Modern Machinery

By JOHN KIRKLAND

ON a commercial scale the method of making bread is very little different from that already described. A slight saving can be effected in the quantity of yeast used. The proportion given for the small quantity is  $2\frac{1}{2}$  lb. per sack (280 lb.) of flour, but for a dough consisting of a whole sack, to stand three hours from time of making to time of scaling, not more than  $1\frac{1}{2}$  lb. of yeast would be needed. The proportion of salt used would be about the same ( $3\frac{1}{2}$  lb. per sack), and the same proportion of sugar would not be harmful ( $1\frac{1}{2}$  lb. per sack). If it were intended to make tin bread only of the large batch, then it would require about 15 gallons of water for 280 lb. of flour; but if cottage and other crusty shapes were wanted, then 14 gallons would be sufficient.

**Fermentation.** With large quantities of dough, it is not easy to regulate the conditions as to temperature under which the dough is fermenting, but the influence of mass prevents the large batch of dough from cooling so quickly as the small dough, while the fermenting action of the yeast within the dough actually generates considerable heat, which the large mass holds, but the small mass allows to escape. The temperature of the water for a sack of flour, therefore, should be less than for a small quantity; for the former  $100^{\circ}$  F. would be hot enough. The reason a smaller proportion of yeast can be used for the larger dough is also due to the influence of mass, which seems to make the yeast activity more intense and more steady. When the large dough is made, as described above, it is allowed to lie in the trough for about 2½ hours, and, if it has been made by hand, it is then cut into pieces, and each piece well kneaded and laid in the opposite end of the trough from that it originally occupied, the whole of the pieces being piled on top of each other until the whole mass has thus been turned over and thoroughly kneaded. The purpose of this operation is to bring the yeast and yeast-food in the dough into closer contact with each other, the effect being to greatly increase the fermenting activity of the yeast. After this the dough is allowed to lie for another hour, when it is thrown out on the table and weighed into pieces of 2 lb. 2 oz. or 2 lb. 3 oz., which is the quantity required to produce the ordinary 2 lb. loaf.

**Purpose of "Handing Up."** Whether the loaves are to be tin loaves or crusty, it is usual to roll, or, as it is called in the bakehouse, "hand up," round, and place on the board or in boxes for some time before finally moulding into the proper shape. The purpose of this preliminary operation is really to make it easier for the baker to get something like uniformity

of shape in his loaves at the finish, and to increase the speed at which the last operation can be performed, so that the first part of the batch does not stand very much longer after moulding, and before it enters the oven, than the last part.

**"Proving" and "Setting."** In some bakeries the practice is to start "setting" the loaves in the oven—if crusty ones—almost as soon as they are moulded, but bulkier and plumper loaves are obtained if they be allowed to lie some time to "prove" before being "set." If the loaves be of "tin" variety, they, of course, must be proved, if any bulk is desired. With this sort of bread the fault is too often that it is overproved, resulting in an open texture, crumbliness, and loss of flavour.

The oven for crusty bread should be about  $450^{\circ}$  F., and the time occupied in baking a batch should be from 40 to 45 minutes. The same temperature will suit for tin bread, for if it be too cold the loaves become overlarge and crumbly. The whole process of baking a sack batch of bread, with this quantity of yeast and under the conditions stated, will occupy from 5½ to 6 hours from the time the dough is made till the bread is drawn from the oven.

**Names of Loaves.** In the ordinary baker's business customers require bread of all sorts and shapes, such as "cottages," "Coburgs," "bricks," "small tops," "sister bricks," "pan cottages," "long loaves," "tins" [6] of various shapes, "twists," "collars," etc. "Cottages" [1] are all crusty, and are made in two pieces, the top part being slightly smaller than the bottom. "Small tops" [4] are nearly the same shape as ordinary cottages, only as a rule they are moulded in flour or cones to make them white, the top is very small as compared with the bottom, and the "closings" of the bottom part are turned upward so that they may open out and show small cracks while baking in the oven. "Coburgs" [2] are round, with two deep cuts in form of cross, so that they open out, and are ultimately of a crown shape, with four points.

The loaves called "bricks" [3] are moulded in two parts like cottages, only, instead of being round, the pieces are in two rolls, the top one much smaller than the bottom. "Sister bricks" are those which are set in the oven in pairs, so that one side of each loaf is crumbly, the other side being crusty. "Pan cottages" are simply ordinary cottages, baked in round pans about  $1\frac{1}{2}$  in. deep, instead of being baked on the bottom of the oven.

"Household" loaves are moulded in two parts like cottages, except that both parts are the same size, or the top part slightly larger than

the bottom, and they are packed close together in the oven, so that there is crust on top and bottom only, the sides being square and all crumby. This type of loaf has gone nearly out of use in England, but is still the common loaf in Ireland, where, however, the practice within recent years has been to mould each loaf in a single piece, depending on their closeness to each other in the proving boxes and in the oven to give them the square shape required. "Scotch loaves" belong also to this crumby variety, with crust only top and bottom; they are not square,

plain flat loaf of an elliptical shape, but pointed at the ends, and with a narrow plait stretched lengthways along the top.

**Local Names of Loaves.** The names given above are those generally accepted for the different shapes of bread, but some of the shapes described have local names. Thus, those called "Coburgs" are in the West of England called "cakes," while in the South of Ireland the same shapes are called "skulls." The same local variations occur with regard to nearly all other shapes. There is no fixed rule as to the length of time

SOME TYPICAL LOAVES

but oblong [7]. The standard shape of this sort is about 8 in. long, 6 in. to 7 in. high, and  $3\frac{1}{2}$  in. broad. The loaves are moulded in one piece and are in rolls when finished, but, being packed close together, the sides and ends become flat. The smooth and glossy appearance of the crumby part of this sort of bread is secured by greasing the sides and ends of each loaf before it is "set" in the oven.

The terms "twist" and "collar" [5] are used respectively to designate loaves made in the shape of a plait pointed at both ends, and of a

dough requires to be fermented, only that hard, strong flours require more fermenting than soft ones. The time required to make bread is, other things equal, determined by the amount of yeast used. Thus, if the dough has to lie in the trough overnight, say, for 10 hours until weighed into loaves, then only 10 oz. of yeast would be used. About 3 oz. of yeast more would be allowed for each hour less the dough had to lie, except that, if it were wanted in, say, two hours, then as much as  $2\frac{1}{2}$  to  $2\frac{3}{4}$  lb. would be needed to get the dough properly "matured" and "clear."

10. DOUGH-DIVIDING AND MOULDING MACHINE  
(Werner, Pfeleiderer, & Perkins, Ltd.)

**Temperature of Dough.** Heat increases the speed of fermentation and cold reduces it; but it is better to depend more on quantity of yeast than on temperature to alter the speed, increasing the quantity to accelerate it, and reducing the quantity if the dough has to lie a long time, keeping the temperature of the dough nearly always alike—for small lots about 82° F., for large lots from 78° F. to 80° F., and for large lots, to stand a long time, from 76° F. to 78° F. Although nothing else is needed but the natural sugar of flour to produce fermentation, it has become a common practice, since the use of potatoes in bread has been abandoned, to use so-called "yeast-foods" in varying proportions in their stead.

**Potatoes in Bread.** Potatoes are in disuse because they were troublesome to prepare, difficult to procure always good, and in other ways unprofitable. Then, as they were used as an aid to fermentation of the slow-working brewers' yeast and home-made barns, the quick-working distillers' yeast now used does not require such assistance, nor does it require to be worked on the old-fashioned three-stage system of "ferment," "sponge," and "dough," which was associated with barns and potatoes; hence potatoes are now very little used by bakers, although some still consider it impossible to make such moist bread without them. Potatoes were used in quantities of from 10 lb.

to 14 lb. per sack of flour, but the yeast-foods now adopted in place of potatoes are used in quantities of 1 lb., 2 lb., or more, according to kind. Those yeast foods may consist of ordinary sugar, which gives the bread a rich bloom and quickens the fermentation process, or of malt flour or malt extracts, which, in addition to producing a "bloom" on crust, are also supposed to keep bread moist and to improve the flavour. There are several preparations of gelatinised starch on the market, used principally for increasing the yield of bread by causing it to absorb more water at dough making. These substances are also supposed to keep bread moister.

Malt flours are used in the proportion of 1 lb. to 1½ lb. per sack of flour; malt extracts from ½ lb. to 1 lb. per sack; sugar from 1 lb. to 2 lb., and the various preparations of starch from 2 lb. to 10 lb. per sack (280 lb.). In addition, there are several patent mixtures used.

**Milk and Vienna Bread.** The greatest improvement that can be effected in bread is by the half or total use of milk in place of water in making dough. This gives it a fine crust, an even texture, a rich colour, and a sweet flavour; but all those qualities can only be secured if care be taken not to get dough over-ripe. To make milk bread use the following: 14 lb. flour, 4½ oz. yeast, 2½ oz. salt, 3 oz. sugar, 3 quarts new

11. A MODEL BAKERY, SHOWING DRAW-PLATE OVEN  
(Werner, Pfeleiderer, & Perkins, Ltd., Peterborough)

milk, or  $1\frac{1}{2}$  quarts milk and  $1\frac{1}{2}$  quarts water. Proceed in exactly the same way as already described for plain bread, but dough should not stand more than two hours until it is weighed into pieces. This may be made into loaves [9], preferably about 1 lb. each, or into "Vienna" rolls [8].

**Glazing.** Loaves may be baked crusty, or in tins, a superior appearance being obtained by washing them over either with egg mixed with a little milk or with a paste made by scalding 1 oz. of cornflour with 1 pint of boiling water. To obtain a glaze with the latter it is necessary to wash the rolls or loaves with it before they are placed in the oven, then they have to be drawn out before they have finished baking, washed over again, and returned to the oven. The best glaze, however, and the sweetest crust is obtained when the loaves or rolls are baked in an oven of which the atmosphere is supersaturated with steam from a boiler and which has a sloping bottom to hold it.

**Recipe for Brown Bread.** As many people prefer brown bread to white, the following method may be successfully used: 8 lb. whole meal—or, if that be very coarse, then 6 lb. wholemeal and 2 lb. fine flour—2 oz. salt, 3 oz. yeast, 2 oz. sugar, and 2 quarts water at  $106^{\circ}$  F. Make all into a smooth dough in the manner already described, and keep in a warm place for 40 minutes. Weigh them into pieces of 1 lb. each, and mould into tins. Allow these loaves to prove in a warm place for 35 to 40 minutes, then bake in an oven about  $420^{\circ}$  F. for 40 minutes. This bread will be found very palatable, and should have the natural sweetness of the wheat still in it.

There are many varieties of "patent" brown breads on the market, several being mixtures of wheat germ and flour or malt extract as their speciality. Some depend on malted wheat and on other grains. Those containing a large quantity of malted meal require to be baked in a very cold oven. They acquire a thick but very sweet crust and moist interior.

**Machinery in Breadmaking.** Within the last few years very great advance has been made in the adaptation of machinery for breadmaking. The small bakers are now installing dough-kneading and mixing machines [10], while the large firms who have used kneaders for many years are now adopting dough-dividers [11] and loaf moulders, and draw-plate ovens [12]. By the use of a full plant such as that just enumerated, it is possible to reduce the cost of labour in the bakery by at least one-third, and in some of the larger places by a greater proportion. Bakery engineers are surmounting one difficulty after another, and the time seems measurably near when the whole process of baking bread will be conducted with automatic machinery.

IN POSITION OVER KNEADING MACHINE  
(J. Baker & Sons, Ltd., Willesden)

**A Revolution in Ovens.** The old type of oven in which coal was burned, and which required each loaf to be set in separately with a long peel, is rapidly giving place to draw-plate ovens heated with steam pipes, and in which the whole batch of bread is "set" or withdrawn at one operation. The steam pipes consist of long tubes—an oven may contain from 70 to 90 of these—each one-third full of water, but sealed at both ends, so that the water or steam never escapes. They therefore supply no naked steam in the oven, but bake the bread with the same kind of dry, radiant heat as other sorts of ovens. But the use of the draw-plate, to which automatic fillers are now being adapted, makes these ovens great labour-saving appliances, while the use of producer gas as the heating agent is likely to ensure further economies in the cost of manufacture. This type of oven bids fair to become the universal type of the future.

## MAJOR SCALES

Ascending and Descending the Scale. Consecutive Phrases.  
The Seven Intervals. Chords. The Pedals. Ear Training

By ALGERNON ROSE

**I**T is the dropping of water which wears away stone. To accustom the fingers, little by little, and gradually, in a way perhaps imperceptible, to do their work with the least possible arm or wrist motion, the student, day by day, should practise Exercise 1, ascending the scale one note at a time. After completing each group of four notes, use special care to get the fingers ready for the fifth note. Try the right hand first. Keep the first and second fingers down. Then try the left hand.

**Reversing the Order.** Mindful that the endeavour must be to prevent and restrain the fingers from falling into errors which a good master would check, the self-trainer cannot be too heedful in preparing the first finger while the thumb strikes the first note; the second finger when the first finger strikes; the third, when the second produces the sound; the thumb, when the third finger strikes, and so on. Try Exercise 2 with both hands, keeping the thumbs well up.

Now attempt the scale, playing two instead of four notes at a time. Here a fresh difficulty presents itself. The beginner will find the manipulation of four successive strings easier than striking two and two evenly, while keeping the thumbs up close to the right string, at the same time that the third and second, and afterwards second and first, prepare themselves to strike. The strings must be struck with both hands simultaneously. Avoid the rat-rat effect of a postman's knock [Ex. 3].

Hitherto the hand has been preserved in one position. This has now to be changed. Take, for instance, the scale of C. As before, play C, D, E with the third, second, and first fingers. Strike the fourth note, F, with the thumb; at the same time, however, pass the third finger under—below the thumb—to the fifth note, G. Get the second finger into position for the A while the G is struck. When the second strikes the A, prepare the first for the B. Get the thumb ready for C when the first strikes the B. In this manner the successive eight notes are played

without interruption or break in the middle part. In changing the position of the hand, take care to bring the third finger down low enough to enable the second and first to get into their right places without undue effort. Bear in mind that, during this change of position, movement of the wrist or arm must be guarded against. The left-hand fingering must be carried out in the same way an octave lower down the scale. Practise each hand separately. Try to strike the strings with equal clearness and strength. When independent facility has been acquired, practise the ascending scale with both hands together in the manner shown in Exercise 4.

In descending the scale, prepare the first finger for B, beginning with the thumb on the upper C. As the first finger strikes, get the second into position for A. Sound the A whilst the third gets ready for G. Now, as the third finger strikes, pass the thumb not under, but over it, so that it drops on F. When the thumb sounds F, the first finger goes on E. As E is played the second finger is prepared for D. The third finger gets into position on the C as the D is struck. Uniform regularity of effect must be aimed at. If the student takes pains at the beginning, this double-action of fingering, or silent preparation concurrently with the production of sound, will be done instinctively. In every respect the motions for the left hand are collateral with those of the right. Exercise

each hand separately. Then descend the scale in simultaneous octaves [Ex. 5].

**Mastering the Gamut.**

It is only by constant repetition and concentration of purpose that the student can count upon playing up and down the scale so that the notes flow evenly with pro-

gressive velocity. The advance made may often appear imperceptible, but can be tested by going back to the first exercise. Always bear in mind that harp playing is an accomplishment. The ability to induce the fingers to strike the strings freely will surely come with

Ex. 1.

[Same fingering both hands]

Ex. 2.

## Ex. 8.

## Ex. 9.

it "perfectly" is impossible. That is why the oldest as well as the youngest students should strive to train their fingers by diligent repetition of this exercise, hoping to arrive at a degree of excellence hitherto unattained. "Transcendental technique," however, is only approached by the harpist realising his own faults and then striving to overcome them. The student should always have in his mind the highest ideals. This will be a great stimulus to him in his endeavours to conquer the digital troubles he may at first find in the range of notes given in Ex. 7.

### Consecutive Eight-note Phrases.

Having obtained comparative proficiency in the two-octave scale, after playing eight notes, go back six. Begin again on the third note. This will give exercise for preparing the third finger to find the E below quickly and accurately while the thumb strikes the C above. After starting afresh on the E, when the thumb arrives at the octave E above let the third finger in the same way prepare itself to fall unerringly on the G below. A fresh group of eight notes is then played up to the G [Ex. 8].

Reverse the operation in descending. Beginning from the top G, when the third finger arrives on the G below bring the thumb over to E, the third note from the top of the scale. Play the octave downwards. When the third finger arrives on the E pass the thumb over and back to the C above. Then play down the octave till the third finger arrives at the starting-point. Without the practical example of a master, the student must give particular care that there is no unevenness during the changes of position. With a teacher to observe and listen to, progress is mainly due

## Ex. 10.

## Ex. 11.

to the faculty of imitation. To such an extent is this carried that objectionable mannerisms, characteristic of certain otherwise great players, are emphasised and made doubly ludicrous in pupils. Fortunately for the student, every genuine lover of music has, born in his brain, a consummate conception, or mental model, to which,

if he is conscientious, he will strive to attain. This summit of ambition, which beckons on those who strive, was called by Napoleon his lucky star. Let the student steadfastly endeavour to be worthy of his lucky star. [Ex. 9.]

**The Seven Intervals.** The student should now learn to play the seven intervals of an octave. Practise first with the right, then with the left hand, and then with both hands together. Beginning with middle C, when the first finger strikes the string the thumb should be in its place for sounding the D. As the D is struck the first finger prepares itself to sound again the C. On this note being repeated the thumb places itself in readiness for E. As the E is struck the first finger again goes back to the C. When the C is sounded for the third time the thumb places itself in readiness for F. These six notes should be played smoothly, as if they were slurred. They comprise the intervals of a second, third, and fourth. The player proceeds now to sound intervals of a fifth and sixth. Let the second finger strike the C. At the same time prepare the thumb for the G above. When the G is struck pass back the second finger in readiness to repeat the C. As this string is struck get the thumb into position to sound the A. These four notes must be played smoothly. Advance to the intervals of the seventh and octave. The third finger now strikes the bottom C. As it does so place the thumb in readiness to sound the B above. When the B is struck prepare the third finger to repeat the C. As the C sounds a second time adjust the thumb for the octave C above. These notes, if read backwards, give the same passage descending. For this, prepare the fingers carefully in the reverse order [Ex. 10].

each note of the scale. In China, each separate sound has a distinctive mental meaning. This septet of pedals is appropriately situated in the pedestal of the harp. Four of the levers are on the right, three are on the left of the player. Beginning from the centre, the right foot negotiates the E, F, G, and A ♯ pedals. The nearest on the left is the B ♯. Then follow, for the left foot, the C and E ♭ pedals. Each slot in the pedestal is furnished with two notches. Put the toe on the left middle pedal, (C ♯), the harp being tuned in this key. If the lever is pressed down to the first notch, a rod in the column is raised. This operates on the metal comb or action in the neck, and puts greater tension on all the C ♯ strings by stopping off a portion of their length, as the violinist's finger does on the fingerboard of the fiddle. The pitch is thus raised uniformly a semitone to C ♯. Depress the pedal to the second, or lower, notch. The leverage action now raises the pitch another half-tone, and transposes all the C ♯ strings to C ♯. In consequence, when certain other pedals have been depressed, there is no more difficulty in playing on the harp in the key of C ♯ than in any other, although a beginner on the piano would find that key, with its six accidentals, or the natural harp scale with its seven flats, most embarrassing.

Take the second pedal from the right, F ♯. Lower it to the first notch. This raises all the F ♯ strings to F ♯. On the piano, the key of F ♯, with its eight accidentals, is most bewildering, whereas the key of F ♯, with only one flat, is quite easy. On the harp, one is as simple as the other. Now depress the pedal to the second notch. This raises all the F strings to F ♯. On the piano, the key of F ♯, with six accidentals in its signature, necessitates the employment of many black notes. Consequently, the fingering for both hands is different to what it would be in F ♯. But the harp player, having put down the necessary pedal, adheres to the same fingering, whether he plays in a key with eight flats, one flat, or six sharps.

**Ear Training.** Hitherto, for the purpose of practising, all the pedals have been up. The harp, therefore, has been in its natural key of C ♯, a semitone lower than the natural key of the piano. This is as well. It does not

diminish their vibrating length, and gives greater resonance to the instrument. But as soon as the fingers have been drilled to do fairly well what is required of them, the ear must be trained to accustom itself to recognise changes of key. This is done by employing the pedals. Now depress all the pedals quickly one notch. What is the result? The pitch of all the strings is raised equally half a tone. The harp is, therefore, no longer in the key of C ♯, with seven flats. Why? Because all the flats have disappeared. Therefore, it is now in the scale of C ♯, and the pitch of the harp corresponds with the piano if the student plays his exercises on the latter instrument without regard to the flats in the signature of the music.

The natural scale of the Highland bagpipes is in the key of G, which has one sharp, F. To interpolate this sharp, press down the F ♯ pedal (now in the first notch, and therefore F ♯) and slip it into the bottom notch. This raises every blue string throughout the instrument to F ♯. It will be appropriate to try, in this bagpipe key, the melody known as "The Campbells are Coming" [Ex. 15].

#### Insertion of Accidentals by Pedals.

Accurate and rapid management of the pedals is an important art with which the student cannot become too familiar. In a

truly diatonic melody, a piece may be played from beginning to end without manipulation of any of the levers after they have been adjusted at the start. In modern harp music, however, modulations of harmony into different keys frequently occur several times during the performance of a single piece. This necessitates on the part of the player an ability to press down, noiselessly, the correct pedal at the right moment.

Now put up all the pedals again. We give an exercise in which a modulation from the key of C ♯ to G ♯ occurs [Ex. 14]. Strike the first three chords in the natural key of the harp. To obtain the necessary F naturals in the four chords which follow, depress the middle right pedal to the first notch. This raises all the blue strings half a tone to F ♯. Practise the exercise slowly with a metronome until the pedal change is made without retarding the time. Then gradually increase the speed until this key change becomes automatic.

# MILLING AND GRINDING

Reciprocating Cutting Tools, and Rotary Machine Cutters.  
The Milling Cutter. Key-seating. Grinding Operations

Group 12  
**MECHANICAL  
ENGINEERING**

24

WORKSHOP PRACTICE  
continued from page 3324

By JOSEPH G. HORNER

THE invasion of the machine shop by tools of new or of vastly improved types has been the cause of much change in methods. These tools include the milling machine, the grinder, the turret lathe, gear cutting machines, key-way cutting machines, and high-speed tools. Some of these machines, though in use more than half a century ago, have lain neglected and undeveloped until within the last few years.

One feature which the milling machine and grinder have in common is that they are rotary tools, and to this fact they owe much of their success. Their rivals are the reciprocating tools—the planer, shaper, slotter, and key-way cutters. Another feature is that these tools, and the machines in which they are embodied, are specially characterised by certain movements and adjustments of fine precision, so much so in fact that they have been the principal agents in the development of the *interchangeable* system of manufacture. In this system not only are precise dimensions easily ensured, but positive dimensions also, alike in any number of similar pieces. And since these results are obtained by mechanism embodied in the machines, and not by the exercise of a high degree of craftsmanship, remarkable economies follow. Precision, both absolute and uniform, with extreme economy in labour was never possible by the old methods. It is regularly obtained by the new.

## Reciprocating versus Rotary Cutters.

In our last article we said that there are several ways of producing similar articles, or similar surfaces in the machine shops. But because the planer, shaper, and slotter formerly monopolised so much of plain surfacing they have been allowed to retain undisputed possession of it until recently. Yet much of this work can be done by rotary milling cutters; some of it as well, some better, than by reciprocating tools. The fact also that these machines appropriated so much led to their use for the production of numerous surfaces which, though plane in one direction, were situated at angles with the vertical or the horizontal, and which, when required to gauged dimensions, are not very readily tooled in this way. We have frequently seen many other awkward shapes done in these machines, such as gear-wheel teeth, long spirals, and other forms requiring special rigs-up, and tedious and costly operations, with unsatisfactory results. Worse than these, too, are profile forms, which include all shapes that involve combinations of faces and curves, convex and concave, regular or irregular in outline. Some assistance can be derived in such cases from tools shaped to suit portions of the profiling, but they are nearly always costly, slow in operation, and unsatisfactory in execution. To-day, these classes of work are better

done with rotary cutters on milling machines than on any of the machines employing reciprocating tools. In profiled forms especially is the economy apparent, for though much of this is taken from these machines, an equally large section is appropriated from hand labour done at bench and vice. In irregularly profiled work done by milling, a cam or former plate of any imaginable shape is made to control the movements of the cutter in a direction perpendicular to the edges of the work being tooled.

**Elasticity of Milling Practice.** The production of plane faces by rotary milling cutters is effected equally well whether the edge or end type of cutter be used [see 258, page 3370]. The advantage of this choice is apparent when the milling cutter is contrasted with the action of the single tool edge. In milling, it matters not whether faces be situated in vertical or in horizontal planes, since either one or other form of cutter will operate on both. An advanced stage is that in which cutters are arranged in gangs, or in series, to operate on vertical and horizontal or angular faces simultaneously at the same traverse, which no single-edged cutter will do; neither will any combination of single-edged cutters in a single tool box. Curved cutters can also be included with those having plane faces.

Yet once more the cross traverse of the single-edged tool is avoided in the milling cutter. Take a surface, say a couple of feet wide. The single-edged tool in roughing this down with one-sixteenth feed will have to make 384 separate traverse movements, and the machine table or the tool as many reversals. The broad milling cutter tools the entire width without any traverse movement, and without any reversal. And often, if wide pieces be not required, and work is wanted for the machines, a number of narrow strips are arranged side by side, and milled simultaneously, as a single wide piece would be, and with at least equal economy.

**Edge Type of Milling Cutters.** Comparing the work of milling with that of the reciprocating tools in the slotting machine and shaper, we see that it stands on a different footing from that done in the planer. In slotter and shaper circular movements are available, as explained in the last article—in the first-named machine by the rotation of the table, in the second by the movements of the tool head in a circular arc, or of the work on an arbor provided with circular feed. But the edge type of milling cutter scores over both, because the cutter does not reciprocate, and it is also generally supported at the lower end in deep work, and thus the spring so objectionable in the reciprocating tool is eliminated, or nearly so. The milling cutter will do work of which the slotting

and shaping tools are not capable, among which are included internal work, as that of plain round holes, and blind slot holes.

The milling machine comes only slightly into rivalry with the lathe, and chiefly in the profiling of light gear-wheel blanks which are liable to be sprung by turning. While turning has to be done by gauge, the milling cutters built up in a gang form produce the blanks to correct shape at once without any tentative settings of tools.

**Limitations of Milling.** In the work of milling, a saw-like cutter having from 8 or 10 to 50 or 60 teeth arranged in cylindrical, or plane fashion, accomplishes similar work to that of the single-edged cutting tool. Each tooth is a separate and distinct cutting tool, but it must not be supposed that a cutter with, say, 20 teeth would accomplish 20 times as much work as the single-edged tool, or that it could be operated at 20 times the speed in cutting. Sometimes it would not get over as much work; it will only do more in some particular circumstances, and it cannot be operated at more than twice or thrice the speed of the single-edged tool. The non-recognition of the reasons for this has often resulted in disappointment, and the condemnation of the milling machine. This type is no exception to the rule that all machines have limitations, and that there is no machine which is capable of the highest economies under all conditions.

The milling cutter lacks the full penetrative power possessed by the single-edged cutting tools. Its edges are weak and thin by comparison, and are easily damaged by forced duty. It can therefore be employed only for shallow cutting. The teeth also are pitched so closely, seldom exceeding  $\frac{3}{8}$  in. or  $\frac{1}{2}$  in. apart, that the cuttings cannot get away so freely as they do from the single-edged tool. This limits the depth and speed of cut. Further, the teeth are broad, while the single-edged tool is narrow-pointed. The power required to operate the milling cutter increases as its breadth, and one advantage which the cutter has when opposed to planing or shaping of plane surfaces, is that of increased breadth. But a broad cutter is very liable to spring and produce untrue work. Again, unless a milling cutter has its teeth of equal length, its full possible advantages are not utilized, because the duty will be thrown on the higher teeth. Faulty cutters, too, have to be reckoned with. Yet the milling cutters are used to an increasing extent, appropriating work from the machine tools using single-edged cutters. The reason is that, employed under proper conditions, they are of high utility, while in some particular cases they perform that which no other tools can possibly do so well or economically.

**Inserted Teeth Cutters.** There is a large group of milling cutters to which the foregoing observations as to fine pitching of teeth, and slight capacity for penetration, do not apply—the cutters with inserted teeth. These are discs, generally of large dimensions, in which single-edged tools are inserted at equidistant spacings. They are not fine tools like the milling cutters proper, but are

used for roughing in “ending machines” and “plano-millers,” and in these capacities are great rivals to the planing machines for operating on plane surfaces of large areas.

In some kinds of work the choice between the reciprocating machines and those using rotary cutters is pretty evenly balanced. There is much work on the border line, in regard to which the opinions of shop managers are found to differ, but this is chiefly that in which plane surfaces are in question. But in others, the choice is overwhelmingly in favour of one method. And in regard to the machine, the question is never what is *possible* of accomplishment, but what is *economically practicable*. We will now take a few examples illustrative of the work of the milling cutters.

**Examples of Milling.** The profiles shown in 265 to 271 are those which would involve more expense with less accuracy if the attempt were made to produce them by planing or shaping processes. If produced by planing, 265 would require five tool settings, whereas with the built-up gang mill shown, it is effected at a single traverse. Moreover, there is the great advantage that the gang tool *faces sizes* also, while planing requires exact setting and measurement for cutting each of the five faces. This milling cutter would produce a number of pieces all alike, whereas planing would result in diversity. Fig. 266 is a still more difficult section to produce by planing, for it involves nine different faces, which must be symmetrical on opposite sides of the centre. The gang cutter produces them simultaneously. Such cutters, of course, are costly to make and build up, and they require careful grinding, and lose their accuracy by re-grinding. But the cost is soon recovered; grinding is a matter for the cutter grinding machines, and accuracy is restored by various adjustments, one of which is shown in 266, effected by right and left-handed screws. These are two examples only, selected from numerous actual combinations. The device is one that is in extensive and increasing use in the shops.

The next example [267] is one which is familiar—the tee grooves in machine tables. These were formerly always planed, if tooled at all, but frequently were left rough-cast, by reason of the time involved in planing five distinct faces. The milling cutter, starting from one end, cuts the five faces simultaneously. Fig. 268 is typical of a large volume of work done by milling—the formation of the grooves in the cutters themselves, previous to hardening. All the grooves in any cutter, or any number of similar cutters, are bound to be alike. The spiral form, which is given longitudinally, is imparted by dividing head gears in a universal machine, being a special class of screw cutting. Figs. 269 to 271 are examples of profile cutting involving curved outlines, 269 and 270 being convex and concave respectively, 271 being moulded. The work produced is the exact counterpart of the cutters, and it is obvious that by no process of planing or shaping could these forms be produced so exactly, except at the expenditure of an enormous amount of time and trouble. Here, therefore, the milling

# MILLING AND GRINDING

cutter scores heavily. Figs. 289 and 290 are examples of this kind of work.

**Profile Milling.** There is another department of work in which the milling cutter holds its own securely—namely, the *profiled* work, or *form milling*, or work of irregular outlines in plan. All the illustrations 265 to 271 are those of work having irregular outlines either absolutely plane [265 to 268] or circular [269 to 271]. But link and cam work is irregularly shaped in plan, irrespective of the sectional form of the edge. If, now, the movements of a milling cutter be controlled so that it must follow certain pre-determined irregular outlines, it will produce *profiled* or *formed* outlines. Any one who has seen gun stocks or hammer shafts being turned on a copying lathe will understand the action of the *form* or *former*. The movements of the cutting tool are coerced thereby, and the irregular outlines of the form are reproduced exactly on the work. This is the principle in form milling [272, 273]. There is no other machine which will do this work except in a makeshift fashion, and large quantities of it are done in milling machines with special mechanism for pulling the cutter in the path embodied in the form.

### Key-seating.

Keyway cutting forms a very large section of the work of the machine shop.

There are keys in nearly all wheels and pulleys, and also in their shafts. The method of tooling these differs. In the old system, still extensively practised, the keyways in wheels are done on the slotting machine, the table of which is tilted when a tapered key-groove is required. Of late years, special keyway grooving machines have been employed largely, in which a serrated cutter bar, or a single cutter moving vertically produces the groove in the wheel or pulley lying on a table. Practically all key-grooving of the bosses of wheels and pulleys is done in one of these fashions, either with a single-edged slotting tool or a serrated-edged bar, each moving vertically.

**Key-seating in Bores.** The two methods of doing key-seating in bores are shown in 274 and 275. In 274, the boss A is clamped

on the table B of a slotting machine, and the tool C is producing the groove. In 275, a half coupling A on the table B of a key-seating machine is being key-grooved by the tool C clamped in the bar D. The reasons why the latter is capable of producing results more accurate and more rapid than the former are as follow: In 274, the tool C is liable to spring, because it is unsupported away from its holder, and is certain to do so under any but very light cuts. Therefore, the operation must be slow or the results are inaccurate. But in 275 the tool bar D is supported absolutely firmly by the bush E, which is fitted into the bore of the piece of work A, and through which the cutter bar D reciprocates. The number of bores required is provided for by having sets of bushes of different

outside diameter but of the same interior diameter to suit the standard bar of the machine. Spring is impossible in this arrangement, and therefore, while several light cuts are required to make a key-groove in 274, a single cut, or two cuts suffice in 275.

While these drawings are under consideration, note should be made of the clamping arrangements. Two very useful packing blocks are shown in 274 at D D, useful because their screws permit of making vertical adjustments to bring the clamping plates E E level, and so suit

bosses of different thicknesses. FF are packing blocks laid under the work to permit the tool to clear the key-groove. Another useful type of packing block, which permits of a range of adjustment for height, is seen at F F in 275. This has four steps, giving four different heights on which the clamping plates G G may rest. Though these do not afford the minute adjustments of D D in 274, they are extremely useful, having broader bearing surfaces, and are largely employed in milling and other machines.

**Key-grooving in Shafts.** When keyways are required in shafts the conditions are different. Bosses are relatively shallow, shafts long, and the latter, therefore, are tooled in a horizontal setting. Keyways in wheels and pulleys are mostly tapered, the case of sliding

280. Grinding circular spindle. 281. Grinding with planet spindle. 282. Grinding a bore. 283. Grinding a bore with planet spindle. 284. Dead centre grinding. 285. Grinding at an angle. 286-287. Chuck work. 288. Facing a bush

feather-grooves excepted. Keyways in shafts are parallel, so that no tilting apparatus is required.

There are three methods of producing these keyways. The most common is termed *slot-drilling* [276]. Here a rotating drill-like cutter, A, with a flat end and central notch is used, and the work is traversed under it, as shown by the arrow. A key-groove of any reasonable length can be started and finished in this way. An alternative to this is planing, or shaping. The shaft is fixed, and is traversed under the tool in the planing machine, or is fixed in the shaper, the tool traversing. The great objection to these methods is that a hole must be drilled first, both at the commencement and termination of the key-groove, to permit the tool to clear itself. Unusual cases apart, therefore—as, say, in very long key grooves or splines cut on the planer, which are beyond the traverse capacity of the slot-drilling machine—planing is not the best method to adopt.

#### Milling Cutter and Slot Drill.

But the milling cutter has come into close rivalry with the slot drill. This is shown in 277, where a milling cutter is seen in its finished groove, producing correct width and depth at once. The slight objection is that when the groove lies within the ends of the shaft the terminations of the groove must be concave. This would not matter in the majority of cases, excepting chiefly where feather-keys have to be fitted, and then the vertical ends of the slot-drill method are wanted. And in by far the larger number of instances the key-

groove comes right out to the end of the shaft, as when wheels, etc., are keyed on at the ends. Then, of course, the cutter runs out freely. The milling cutter in 277 produces a groove more quickly than the drill in 276, because of its greater slogging capacity, with less risk of fracture if forced. Very frequently several such mills are mounted on one arbor, with distance washers between, and cut the grooves in several shafts simultaneously.

**Elements of Grinding.** The work of grinding is peculiar. The highest degree of accuracy possible in machined work is not produced by the hardened steel cutters that do not wear appreciably, but by the grinding wheels that are themselves abraded practically as rapidly as they abrade the material operated on.

A wheel that is traversed along a shaft, grinding as it goes, is smaller at the termination than at the beginning of its traverse, yet it produces a parallel shaft, accurate within some fractional part of a thousandth of an inch. This seems para-

doxical, but the fact is indisputable. Practical points have to be observed, otherwise the results would be unsatisfactory. The most important one is that no appreciable pressure must be exercised between the wheel and the work. The barest contact suffices to remove material. It is usual to feed wheels inwards by from half a thousandth to a thousandth of an inch only at a time. If more pressure is put on, the work becomes heated and distorted, and runs out of truth to an increasing extent.

**Work Suitable for Grinding.** The place of grinding is limited almost wholly to plane surfaces, to surfaces plane in one direction and curved transversely thereto, and to cylindrical surfaces, external and internal. A grinding wheel cannot produce formed work accurately by its own shape, because traverse movement is essential to its proper action, due to the fact of its own abrasion. In working

on plane, or on cylindrical faces, either the wheel or the work must be traversed laterally, it matters not which, but such a movement is clearly impossible in grinding grooves. Thus, excepting for some comparatively rough jobs, as saw gumming, wheels with convex edges or profiled edges are seldom used.

At present, in the machine shop the work of the grinding wheels is mostly as an accessory to that of other machines—that is, it is employed more as a *corrective* than as a *formative* process. It usually follows roughing operations performed in planer, shaper, lathe, or

automatic machines, and is reserved for work requiring the highest degree of accuracy and finish.

**Types of Grinders.** Grinding machines, which occur in scores of designs, may be divided very broadly into two groups, the non-precision and the precision types. The distinction between the two is this: In the former, no provision exists for producing precise dimensions. If these are secured it is only by methods of trial and careful checking and manipulating on the part of the workman. In the latter, movements precise and absolute are embodied in the machines. The distinction is of vast importance in economical production as well as from the point of view of accuracy. To produce a number of pieces all alike in regard to dimensions, so as to be interchangeable, is, in the first, practically impossible, but in the second it is readily accomplished. The difference is akin to that of turning in the hand lathe with tools held in the hands and turning done in

289. FORM MILLING ON A HERBERT MACHINE

the slide-rest of the self-acting lathe. But the difference in non-precision and precision grinding is more marked, because the latter embodies micrometric adjustments which are absent in ordinary lathes. If a man has to grind a piece to a dimension within a thousandth, or half a thousandth of an inch, he is able to do so by graduated settings in the machine, after which the cut may be taken without anxiety.

#### Sphere of Non-precision Grinders.

Both these great groups of machines fill an essential place in the shop because it is folly to employ high-priced, delicately-constructed machines to do comparatively rough work. Plenty of work has to be ground and polished for good appearance simply, with the advantage of costing far less than the machining of it would cost in lathe, planer, or shaper. Such work is done on the grinding machines that are unprovided with any mechanism of precision, the work being held in the hands only, or moved about on a table or rest against the wheels. The tendency now is to add tables and rests with semi-precise adjustments to the wheels used for rough grinding, so causing them to approximate somewhat to the higher precision types. This is due to the growth of the substitution of grinding for the work of the machines using cutting tools.

#### Examples of Grinding.

The groups of figures 278 to 288 illustrate some typical operations. Figs. 278 and 279 show the production of true plane surfaces of larger or smaller area by grinding. Either style of wheel may be used to produce like results, either the periphery of the cylindrical wheel [278], or the end of a cupped or a ring wheel [279]. Traverse movement is essential. Incidentally, in regard to clamping arrangements, the thin strip in 278 (which may be a slide-bar, for example) cannot be held by clips on the top, because that would interfere with the grinding wheel. In the method shown, which leaves the top face free, small plates A, A, are placed between the work and the clamping bolts, and plates pulled down by the bolts press upon A, A, jamming them angularly as seen, so that they draw the work down to the table. In the side view [278], only one such clamping outfit is shown, but there may be two, one at each end of the work, on each side, or three or four if necessary. A block is sometimes bolted down at the end of the strip to take the end thrust properly, but this is more

necessary in planing and milling. If the strip were very short it might be held just as well in a machine vice. In 279 another type of slide bar, A, is bolted against the vertical face of the angle plate B, the latter being bolted down to the table.

In the example, 280, the most common kind of precision operation is illustrated, that of grinding circular spindles. The wheel and the work rotate in directions similar to each other, so that at the point of contact, while the wheel may be running downwards, the work is travelling upwards. The wheel runs at a much higher speed than the work. At the same time a traverse or longitudinal motion is imparted either to the wheel or the work, either arrangement being adopted in machines by different makers. This traverse motion is indispensable in all grinding, even though the width being ground be no greater than that of the wheel.

The reason is that the particles of abrading material become broken off continuously so that the wheel does not present a true face like that of a steel tool. Therefore a sideways motion is essential for the narrowest as for the broadest or longest surfaces in the production of true results.

#### Differences in Grinding and Cutting.

Only a minute amount of material is removed at each cut or traverse. A lathe tool will commonly cut  $\frac{1}{8}$  in.,  $\frac{1}{4}$  in., or  $\frac{1}{2}$  in. deep into the metal, and often more. But  $\frac{1}{100}$  in. is a coarse depth of cut for a grinding wheel. The difference is to be sought partly in the wheel, and partly in the character of the cutting.

The grinding wheel is composed of fine, sharp, hard particles of gritty materials united with cementing substances. These particles being so small have not the capacity for penetration that the incisive wedge-shaped steel tool has. If the wheel be forced too deeply the particles simply become choked, or *glazed*, and cease to be operative. The depth of cut is limited by the rate at which material can be removed, and this is governed by the efficient action and duration of the edges of the cutting particles, and this again by freedom of escape of the abraded material, and also of the grains that lose their cutting power. This partly explains why, in the best modern grinding, floods of water are directed on the areas being ground to wash away the swarf. Another reason for the water is that the rate of grinding is dependent on the heat generated, which also follows from the abrasive character of the operation, and which is greater than that produced by a single-edged cutting tool.

280. DOUBLE FORM-MILLING ON A BROWN & SHARPE MACHINE

**Function of Water.** When grinding, sparks are incessantly given out, even though lubrication be abundant. It is a fact that sparks are emitted even when the amount being removed is inappreciable by any shop measurements, or, say, some very fractional part of  $\frac{1}{1000}$  of an inch. Now, where sparks are produced there is heat, and the generation of heat is one of the greatest difficulties in grinding, and this is the principal reason why water is so freely used. Take a long spindle like that in 284A. A similar piece of work is shown in 291. Such a piece of work under heavy grinding will bend so much as to destroy absolutely both the circular form and the longitudinal accuracy. Though revolving rapidly, one side—that next the wheel for the instant—becomes hotter than the side opposite, and expands and elongates, and the spindle gradually bends, and is ground elliptically. This would always occur but for the fact that extremely light cuts are taken and abundance of water used. The value of water is due to the fact that the risk of distortion is lessened.

But what is lost apparently in the extremely fine depth of cut possible with grinding wheels is largely compensated for by the high speed at which reduction is effected. Grinding wheels have a peripheral speed of about 5,000 ft. per minute, against from 20 ft. to 150 ft. of single-edged cutting tools, and this tells heavily in favour of the grinding wheels, with the result that there is much work now relegated to the grinding machines that was formerly done on the machines using ordinary cutting tools.

#### Grinding by Planet Spindles.

The example given in 280 is that of a spindle being ground while rotating in a machine against a wheel. But very often such rotation of work is not possible.

Then it might seem as though the work must go to the shaper or slotter or drilling machine to be tooled by one of the devices illustrated in the previous article. That, however, is not necessary, for it can still be ground in another kind of machine in which the wheel moves round the work [281] by what is termed a *planet motion*.

There are several types of machines made in which the wheel itself, rotating on its own axis, has also a movement of its axis in a circle. Obviously, it is then also easy to grind internal surfaces, bores, as at 283, the wheel only moving. This system, originally used for bush grinding in such work as locomotive rods and link motions, is now employed for larger work, specially for the bores of motor cylinders, formerly done in a lathe or boring machine.

291. CYLINDRICAL GRINDING (Cincinnati Machine)

It will be observed that the condition which renders the planet movement of the spindle essential is that the work, whether pin or hole, be fixed, because its size or shape prevents revolving being conveniently effected. This is a different condition from that which exists when the work can be rotated as in 282. This last is identical with external grinding [280], so that the grinding wheel may rotate on a fixed axis, and so be fed perpendicularly towards the rotating work as the grinding proceeds. With the work fixed [281, 283], the axis of the wheel must move in a circle, but the diameter of this circle is made capable of micrometric regulation in the machine, so that precision grinding within a fraction of a thousandth of an inch is possible. The diagrams 230 and 282 and 281 and 283 clearly show the essential distinction between the two kinds of circular grinding.

It need hardly be stated that the attempt to grind out a hole with a wheel of the correct size (in boring tool fashion) could not be adopted, because of the constant reduction in the diameter of the wheel owing to wear.

**Miscellaneous Examples.** Succeeding figures show the general relations of work

292. CUTTER GRINDING (Cincinnati Machine)

and wheel in plain cylindrical grinding. The piece of work A [284] is being driven on *dead centres* by the pulley B against the grinding wheel C. This dead centre grinding is conducive to accuracy, because the headstock mandrel does not revolve, but the pulley B only rotates the work on the conical centres as shown. Provision

is made for rotating the mandrel when necessary, such as for work which must be held in a chuck. Tapers are ground readily, whether external [285] or internal, provision being made in the machine for setting work and wheel spindles to any degrees of angle by graduated scales. The traverse of the wheel is still essential.

Much work is held in chucks, exactly like lathe chucks, for grinding holes [286], and flat discs [287]. Traverse is imparted to the wheel axially in 286, and transversely, or across the face, in 287, the wheel being indicated at A. Another way of grinding faces is seen in 288, by the shouldered face of a wheel. Here the piece of work, a bush, A, is having a face trued up squarely with the wheel B, the wheel being traversed in a direction perpendicularly to the axis.

All these operations will be recognised as legitimate work for the lathes, and some of them also for the drilling and boring machines. Yet they are regularly done on the grinders on hardened pieces as well as soft, and the important point is, with greater accuracy, often combined with greater rapidity than they can be effected in lathes or drills.

**Hardened Work.** Then there is a class of work, that which is hardened, that can be done only by the grinding wheel, because common cutting tools will not touch it. Although it might seem as though this fact could not increase the volume of work produced by grinding, yet it has done so in this way: Many spindles and bearings are now hardened that were formerly left soft in the days when precision machines had not been developed so extensively. The result is greater accuracy, combined with durability in service. There is no alternative to grinding when hardened work is in question; lapping with loose grains of powder on a lead lap or plug has but a limited use, and is disappearing before the competition of solid wheels. Grinding is not only used for hardened steel spindles, but for case-hardened pins and links and the edges of cutters, and the wheels grind these as easily as the softest brass.

**Cutter Grinding.** There is one great department of grinding which has been practically created by the growth of the milling machine, that of *cutter grinding*. The accuracy of the work of milling cutters depends on the accuracy and uniformity of their teeth. These

(such as the type in 268) are ground with emery, corundum, or carborundum wheels in special machines which contain provisions for presenting the wheels in various positions to the teeth of the cutters, no matter what the shape of the latter may be. Each tooth is ground along separately, a stop arresting the tooth and locking it in position, so that the wheel grinds one after another successively until the circle is complete, as in 292. The sharpening may sometimes be between the teeth, instead of on their edges, in the case of "formed" cutters. This is a sub-department of the machine shop, and it includes the grinding of the flutes of taps and reamers.

**Varieties of Grinding Wheels.** Much of the skill of the grinder consists in selecting wheels of suitable grades for different metals and alloys. There are about 60 grades made—hard and soft—coarse and fine, but about a dozen of these suffice for the work of the machine shop. Afterwards the essentials are the speeds most suitable, the rates of feed, the width of wheel, and certain little adjustments of wheels to work effected by the slides of the machine, which can be gathered only in actual working.

The reasons of the fine precision and uniformity of results in the grinding machine, therefore, do not lie in the same category as those of the turret lathes. The grinder at present does not rank as a roughing machine, though it probably will in the near future. Its value lies in fine and precise finishing, exceeding in minuteness that which is commercially possible in the lathe or planer or milling machine. It therefore supersedes the hand scrape with which the work of these machines has been supplemented, and accomplishes the results in a fractional part of the time occupied in scraping. It renders possible the use of hardened spindles and slides in place of softer articles, and without any material increase in cost, because the wheel is as well adapted to operate on hard as on soft materials. But precision grinding requires machines the movements of which will operate with great accuracy. These have much developed in recent years, and are still being improved upon. Grinding is not yet employed to the same extent as milling is, but it is advancing very rapidly, and a few years more will see it employed for work that is still done mostly in the old machines.

*Continued*

# SHORT DICTIONARY OF MACHINE & FITTING-SHOP TERMS

This Dictionary embraces only operations carried on. Definitions relating to the various lathes, machine tools, tools, chucks, and other appliances are given when dealing with those subjects.

**ADJUSTABLE STRIPS**—Metal strips by which compensation for wear of machine slides is effected.

**Adjustments**—Slight movements and corrections effected during the setting of work in machines, and during its subsequent erection.

**Angle Plate**—A casting having two faces at right or other angles, and used for the attachment of work on machines.

**Angles of Tools**—The angles included between the two faces of cutting tools. They range from just below 90° to about 20°.

**Angular-hole Drilling**—Producing square, triangular, and other pentagonal holes by means of a cutter, which is moved in a path corresponding with the shape in plan of the hole.

**Angular Thread**—A screw thread, the section of which is an acute angle, as distinguished from a square thread.

**Annealing**—Softening hard steel to relieve it of internal tension, or to render it easy to machine.

**Arbor**—A spindle or mandrel for holding cutters or work upon.

**Arboring**—Facing a boss around a hole, with a cutter termed an *arboring tool* held in a stem.

**Arc of Contact**—The distance occupied by a pair of gear teeth in mutual contact, the measurement being taken on the pitch line.

**Arc Pitch**—The pitch of gear teeth measured round the arc of the pitch line.

**Automatic**—A movement, operation, or arrest of motion, embodied in a moving mechanism without direct intervention of the attendant.

**Axial Pitch**—The pitch of a single helix in a multiple-threaded screw, measured in the longitudinal axis.

**BACKING OFF**—Imparting clearance back from the cutting edges of tools and cutters. Applied specifically to milling cutters, reamers, and taps. Also termed *relieving*.

**Back Steady**—A support for long, slender work being turned in the lathe, or to similar work being ground. It may be a fixed or a travelling steady.

**Bare**—Signifies that a dimension is very slightly below absolutely correct dimensions.

**Bedding**—Making a proper fit of an element of mechanism on another, or of a mechanism on its foundation.

**Bench**—A bench provided with a vice and drawer is used by fitters. It has a timber top carried on supports of iron or wood.

**Between Centres**—Setting work for turning or grinding between the point centres of the fast and loose headstocks.

**Bevel Gears**—Toothed gears, the pitch planes of which are conic frustra.

**Black Bars**—Bars of iron or steel used as they leave the rolls.

**Black Holes**—Cored or forged holes, as distinguished from those which are drilled.

**Black Nuts**—Nuts which are not machined or polished.

**Black Work**—Castings and forgings which are not machined.

**Blank**—A piece of metal or alloy machined in readiness for subsequent detailed operations in other machines.

**Blank Flange**—A flange which closes the end of a pipe.

**Bob**—The weight on the plumb line. A polishing bob.

**Bolt**—A screwed fastening having a head solid with the shank, and a nut tapped to fit the screwed end.

**Bore**—A hole. To *machine* a hole is to bore it.

**Boring**—Usually the enlargement of a hole already existing.

**Boring Collar**—A cone plate.

**Borings**—The chips removed by a drill or boring tool.

**Boss**—A circular piece through which a hole is made. The boss gives the necessary depth or thickness to the hole.

**Bossing**—Turning the outsides of bosses in a lathe, a drilling, or a boring machine.

**Bracket**—An angular casting or forging which carries some form of bearing or anchorage.

**Brasses**—The loose linings of shaft bearings made in that alloy or in gunmetal.

**Brass Work**—Steam or water fittings made in the copper alloys.

**Bright Bars**—Bars which are planished or polished, so that they have not to be turned in the lathes and automatics, except where reduction is necessary.

**Bright Nuts**—Nuts which have been machined and polished.

**Bright Work**—Work which is machined and polished.

**Buff Wheel**—A polishing wheel of wood covered with leather or emery-powder. The work is termed *buffing*.

**Burnisher**—A piece of smooth steel, or a half-round file with the teeth ground out. It is used for polishing filed work by friction, termed *burnishing*.

**Bush**—The internal lining of a bearing. It is of copper alloy or a white metal, and is fitted by driving in, termed *bushing*.

**CAP**—The cover of a divided shaft bearing.

**Card Wire**—A brush made of steel wires used for cleaning the teeth of files.

**Carrier**—A looped piece of steel which clips an object to be driven between centres. Also termed a *dog*. See *driver*.

**Cast Steel**—Used for cutting tools in all shops.

**Catch Plate**—A small face plate which holds a driver. See *driver*.

**Centre Line**—Dimensions on circular and other bodies are generally taken from centre lines, which are the first dimensions to be laid down.

**Centre Pops**—Dots marked by a centre punch along the course of dimension lines.

**Centre Punch**—A pointed tool struck by a hammer to produce shallow conical depressions, or *pops*, and centres.

**Centres**—The mathematical point whence circles are described. The term also signifies the conical supports used in lathes and other machines for the support of work, either revolving or fixed.

**Centring**—Marking the centres on shafts, bars, and other work.

**Chalk**—Used for whitening the rough surfaces of castings and forgings, to show up the lines and centres scribed by the liner-off.

**Chatter**—Vibration during machine operations due to insufficient rigidity of the tool, work, or machine.

**Checking In**—Fitting parts one within the other by a projection and a seating. Also termed *registering*.

**Check Nut**—A lock nut.

**Chipping**—Cutting metal with a cold chisel driven with hammer blows.

**Chipping Strips**—Strips standing slightly above a broad surface, to be levelled by chipping, instead of by cutting over the whole area of the surface.

**Chord Pitch**—The shortest distance between the centres of adjacent teeth of gear wheels.

**Chucking**—The attachment of work to the chucks or holders.

**Chucking Reamer**—A reamer with a parallel shank to be held in a self-centring chuck.

**Circular Nut**—A round nut with holes drilled in it for a Tommy. Used on many machine spindles.

**Circular Pitch**—Equals the division of the circumference of the pitch line of a wheel by the number of its teeth.

**Clams**—The soft loose jaws of vices.

**Clean Cut**—A cut surface which is smooth and not striated in any way.

**Coarse Feed**—A large relative amount of traverse imparted to a cutting tool.

**Cold Chisel**—A chipping chisel.

**Collar**—A ring encircling a shaft or spindle.

**Cutter**—A small loose cutting tool fixed in a bar instead of being provided with a solid shank.

**Cutting Angle**—The angle included between the two faces of a cutting tool.

**DEAD LEVEL**—Absolutely level.

**Dead Size**—Work produced to an exact dimension.

**Diametral Pitch**—Equals the number of teeth in a wheel to one inch of the pitch diameter.

**Dog**—A carrier. Jaw of a lathe chuck.

**Double-threaded Screw**—A screw with two helices half a pitch apart.

**Draw Filing**—Smoothing a surface by working a file along it nearly at a right angle, and parallel with the work.

**Drawing-on**—Pulling wheels over their axles.

**Drilling Template**—A templet of sheet or cast metal having holes in it as guides for drilling by.

**Drip Can**—A can containing soapy water which drips on the points of a cutting tool, so lubricating and keeping it cool.

**Driven**—A wheel or pulley which is actuated by another.

**Driver**—A wheel or pulley which actuates another, or others. An appliance for rotating lathe work.

**Driving Fit**—A shaft or bush which fits in such a way that hammer blows are required to drive it into place.

**Drum**—A wide belt pulley; also a hoisting barrel.

**Drunkon Screw**—A screw thread which has a wavy outline.

**EMERY**—Used for abrading and polishing, in the form of paper, cloth, powder, and consolidated in the form of wheels.

**Erecting**—The final putting together of mechanisms, following the preparation of their individual sections in other departments.

**Even Pitch**—The pitch of a screw being cut in the lathe is even when it has the same number of threads as the lead screw, or some aliquot parts of the same.

**Expanding Mandrel**—A mandrel capable of slight enlargement to suit bores of different sizes.

**External Thread**—A screw cut on the outside of a cylinder.

**FACING**—Turning a plane surface. A definite area standing above the general surface of a casting, or forging.

**Fair or Flush**—Signifies that surfaces are in one plane.

**False Key**—A key in the form of a pin driven into a hole drilled half way into a spindle and half way into the bore.

**Feed**—The amount of traverse of a tool, or work, during cutting.

## MACHINE AND FITTING-SHOP TERMS

**Feed Screw**—A screw which imparts feed to a machine tool.

**Female**—A recessed or internal portion of a fitting, as a female gauge, or female screw.

**Fine Feed**—A small amount of traverse imparted to a tool in a machine.

**Finishing Cut**—The removal of the last portion of metal from a piece of work, being usually a slight amount.

**Fitting**—The minor adjustments of pieces of work previously prepared in other departments.

**Flange**—An expansion or extension on a casting or forging, used as a means of attachment with screw bolts.

**Flesh Side**—The rough side of leather belts.

**Following Steady**—A travelling stay. See *back steady*.

**Form, or Former**—A templet or guide by which a tool is controlled in producing work of irregular outlines.

**Fractional Pitches**—In screw cutting, pitches which are not aliquot parts of the pitch of the lead screw of the lathe.

**Frosting**—Light scraping done at various angles for good appearance.

**Full**—Signifies that a dimension is slightly over an absolute dimension.

**Full-size Drawing**—One that represents the actual dimensions of an object.

**Full Thread**—A thread which is cut to its proper depth.

**GAS THREADS**—Screw threads of finer pitch than the Whitworth, and made in a much smaller range of number of threads per inch.

**Gauging**—Measuring work by methods of contact instead of by a rule.

**Gears**—Any arrangements for the production of motion, as belts, toothed wheels, valve motions, etc.

**Gear Wheels**—Toothed wheels.

**Glut**—A block by which pressure is imparted, or by which wear is taken up, or a false key.

**Grain Side**—The smooth side of leather belting.

**Grinding**—Usually understood as that done on emery-wheel grinding machines with precision movements.

**Grindstone**—Used chiefly for grinding cutting tools with single edges.

**Gromet**—A washer made of spun yarn, in the form of a ring, used in making water-tight joints under bolts.

**HACKING**—Truing a grindstone with a chisel-like hammer.

**Hard Metal**—Metal which is tooled with difficulty.

**Heating**—The rise in temperature of journals and their bearings, due to insufficient lubrication.

**Heavy Cut**—A deep cut, combined with a coarse feed.

**High-speed Tools**—Tools of self-hardening steel that cut rapidly, and which are not injured when working at a high temperature.

**Honing**—Imparting a fine edge to a cutting tool on a hone or oil stone, subsequent to grinding.

**Hub**—A boss.

**Hunting Cog**—An extra tooth in one gear wheel of a pair, to prevent the same teeth coming together regularly into engagement.

**IDLER or IDLE WHEEL**—One which changes the direction of motion or fills a space, without affecting velocity ratios.

**In Gear**—Toothed wheels having their teeth intimately engaged are in gear.

**In Line**—Signifies numerous centres or facings in one horizontal plane.

**Insertion**—Sheets inserted between flanges to render metallic joints steam tight.

**Interchangeable**—The fitting of identical parts as they leave machines, without any correction by hand.

**JACKING UP**—The lifting and adjusting heavy work through small distances by the erectors.

**Jam Nut**—A lock nut.

**Jenny**—A short crowbar, or pinch bar.

**KEYING UP**—Securing wheels and pulleys to their axes by the insertion of keys.

**Key Bed, or Key Seat**—The groove formed for the reception of a key.

**Keywaying**—Cutting keyways.

**Kink**—An abrupt bend or angle in a piece of metal.

**LAGGING**—Covering engine cylinders with a casing of sheet metal, or of strips of wood.

**Lap**—A body of lead, tin, or wood charged with emery powder.

**Lapping**—Grinding and polishing by means of a lap.

**Lath**—A strip of wood used for taking a dimension.

**Lathe Dog**—A carrier.

**Lathe Work**—The work of the turnery.

**Lead Hammer**—Used for hammering polished metal without bruising it.

**Lead Screw**—The lathe screw, the pitch of which is the first factor in screw cutting.

**Left Hand**—Relates to the direction of some screw threads, of spirals of drills, and of bending in single-edged tools.

**Light Cut**—The removal of a small quantity of metal in a machine.

**Lining Off, or Lining Out**—Marking the working lines on castings and forgings as a guide for the turners and machinists.

**Live Spindle**—A spindle which rotates. Specifically the spindle of a lathe driving headstock.

**Loose Centres**—Machine centres.

**MACHINE TOOL**—A machine by which cutting tools are operated by power.

**Machining**—Cutting metal by the aid of machine tools of all kinds.

**Main**—The principal element, as main belt, main pulley, main screw, etc.

**Male**—An external element, as a male gauge, male screw.

**Mandrel, or Mandril**—A spindle on which bored work is carried for turning. Also an *arbor*. The lathe spindle.

**Marking Off**—The same as *lining off*.

**Marking-off Table**—A cast-iron table, on which work is marked out.

**Milling**—Shaping metal with milling cutters. Knurling the heads of screws.

**Multiple Cutting**—Machine operations employing several tools simultaneously.

**NOSE**—The front end of a spindle or mandrel.

**OIL FEED**—The means adopted for feeding oil to bearings.

**Oil Grooves**—Grooves cut in the faces of journal bearings to distribute the oil over the journal surface.

**Out of Gear**—Toothed gears having their teeth disengaged.

**Out of Truth**—Denotes a condition of inaccuracy in work.

**Over All**—A dimension which is the sum of numerous smaller dimensions in one plane.

**PICKLING**—Immersing castings in dilute sulphuric and nitric acids to remove scale previous to machining.

**Pitch**—The distance between centres of adjacent wheel teeth measured on the pitch line.

**Pitch Chain**—Chain composed of flat links. Used for much machine driving.

**Pitch Line**—Corresponds with the velocity lines of toothed wheels.

**Plumb**—Truly vertical.

**Poker Filing**—Draw filing.

**Press Fit**—A fitting of parts that requires considerable pressure.

**Prising**—Turning or moving an object with a crowbar.

**RAKE**—The angles of cutting tools; as front, bottom, or side rake.

**Reamering**—Smoothing and finishing drilled holes with reamers.

**Reboring**—Smoothing, with enlargement of the bores of cylinders which have become inaccurate by wear.

**Rechucking**—Putting work into a new position in a lathe chuck to present a fresh portion for turning.

**Resetting**—Turning a piece of work into a new position in a machine to present a fresh portion for tooling.

**Roughing Cut**—A first cut taken on a casting or forging. It is coarse and heavy by comparison with the finishing cut.

**Rust Joint**—A water-tight joint made between iron and iron. Iron borings and sal-ammoniac are used.

**SCRAPING**—A finishing operation following filing, planing. It is adopted when very true plane surfaces are required, as for machine slides.

**Screw Cutting**—Generally denotes the cutting of screws in a lathe, with a single tool.

**Screwing**—The cutting of screws with dies in stocks, or in screwing or automatic machines.

**Scribing**—Marking lines with a scriber point held in the hand, or in a scribing block, or surface gauge.

**Self Acting**—Relates to automatic movements in machine tools.

**Sliding Fit**—A mutual fitting of parts which permits of easy sliding, but without appreciable slackness or stop.

**Soapsuds**—Soft soap used for the lubrication of cutting tools.

**Soda**—Used in water for the lubrication of grinding work to prevent rusting.

**Solid Tools**—Tools with shanks, as distinguished from cutters.

**Speeding**—Calculating the speeds of pulleys, gears, and their sizes.

**Sponge Cloths**—Used for wiping oil from machines and work.

**Straining Line**—A fine wire strained between points to obtain a true plane test, for setting or checking the alignment of objects.

**Surfacing**—The same as *faring*.

**TAKING UP**—The making of adjustments to compensate for the wear of slides and other elements.

**Tapping**—Cutting internal screw threads with screw taps.

**Tapping Hole**—A hole drilled to the size of the bottom of a screw thread to be cut in the hole. Also the operation of cutting the thread.

**Templet**—A pattern from which a piece of work is lined out or machined.

**Tommy**—A round bar used for insertion in the holes in circular nuts to turn them by.

**Tool Holder**—A bar for holding and operating loose cutters.

**Transverse Cut**—Cutting done at right angles with the axis of a piece of work.

**Truth**—Accuracy in machining and fitting.

**Turning**—Includes the production of all plain external cylindrical surfaces, and plane faces in lathes of all kinds.

**Turnings**—The shavings and comminuted chips removed in lathes.

**Turret Work**—All work done in turret lathes and automatics.

**VEES, VEE STRIPS**—Angular strips by which adjustments are effected to compensate for wear.

**WIRE EDGE**—The slight arris which is turned over in sharpening a cutting tool.

**Work**—Commonly used as a noun, to denote any piece on which operations are being performed.

# EVOLUTION AND INDICES

Square Root of a Multinomial. Index Laws Proved for Positive, Fractional, and Negative Indices. Examples

Group 21

ALGEBRA

continued from page 2294

By HERBERT J. ALLPORT, M.A.

## EVOLUTION

106. The process of forming a power of a given quantity is called *evolution*. The reverse of this—i.e., the operation of finding a root of a quantity—is called *evolution*.

It is clear that there is only one quantity which is equal to, say, the third power of 2; namely, 2<sup>3</sup>, or 8. But, on the other hand, there are three cube roots of 8.

For, let  $x$  denote the cube root of 8, so that

$$x^3 = 8;$$

or

$$x^3 - 8 = 0.$$

Then  $(x-2)(x^2 + 2x + 4) = 0$ , from which we find  $x = 2$ , or  $x^2 + 2x + 4 = 0$ . The roots of this latter equation are *imaginary*. [See Article 98.] Their values are

$$\frac{-2 \pm \sqrt{-12}}{2}$$

Thus, one cube root of 8 is *real*, the other two are *imaginary*.

We cannot then, strictly, speak of the  $n$ th root of a given expression. But we may take the following as our definition: If an expression, when raised to the  $n$ th power, becomes equal to a given expression, it is called an  $n$ th root of the given expression.

107. The  $n$ th power of a monomial expression is obtained by multiplying the index of each of its factors by  $n$ . For

$$(a^x)^n = a^x \cdot a^x \cdot a^x \dots \text{to } n \text{ factors,}$$

and each of these  $n$  factors,  $a^x$ , consists of  $x$  letters multiplied together, so that altogether we have

$$(a^x)^n = a \cdot a \cdot a \cdot a \dots \text{to } nx \text{ factors} = a^{nx}.$$

Similarly, we see that

$$(a^x b^y c^z \dots)^n = a^{nx} \cdot b^{ny} \cdot c^{nz} \dots$$

It follows, conversely, that to obtain an  $n$ th root of a monomial expression we must *divide* the index of each factor of the expression by  $n$ .

Examples. One value of

$$\sqrt[3]{x^6 y^3 z^3} \text{ is } x^2 y z.$$

One value of

$$\sqrt[n]{a^x b^y c^z} \text{ is } a^{x/n} b^{y/n} c^{z/n}.$$

## SQUARE ROOT OF A MULTINOMIAL

108. In Article 32 we saw that the square of a binomial is made up of the square of each of the terms and twice the product of the terms.

Thus

$$(x \pm a)^2 = x^2 \pm 2ax + a^2.$$

Conversely, we obtain the square root of a trinomial which is a complete square as follows: Arrange the expression in either ascending or descending powers of some letter, take the square root of the first term and of the third

term, and place between them the sign of the middle term of the trinomial.

Example 1. Write down the square root of

$$9a^2 + 12ab^2 + 4b^4.$$

The expression is already arranged in descending powers of  $a$ . The square root of the first term is  $\pm 3a$ , and of the third term is  $\pm 2b^2$ . Hence the square root of the trinomial is

$$\pm 3a \pm 2b^2, \text{ or } \pm (3a + 2b^2).$$

Although, as we have pointed out, there are two square roots of an expression, we generally consider only the root whose first term is positive. Thus, the square root in Example 1 would be  $3a + 2b^2$ .

Example 2. Find the square root of

$$\frac{1}{4}x^4 y^2 + \frac{1}{2}y^6 - \frac{3}{4}x^2 y^4.$$

Arranging in descending powers of  $x$ , we have

$$\frac{1}{4}x^4 y^2 - \frac{3}{4}x^2 y^4 + \frac{1}{2}y^6.$$

The square root of the first term is  $\frac{1}{2}x^2 y$ , and of the third is  $\frac{1}{2}y^3$ ; the sign of the middle term is  $-$ . Hence the required square root is  $\frac{1}{2}x^2 y - \frac{1}{2}y^3$ .

109. If a *multinomial* contains only two powers of some particular letter, we can find the square root in the same way.

Example. Find the square root of

$$4a^2 + 9b^2 + c^2 - 6bc - 4ca + 12cb.$$

The expression involves  $a$  in two powers only, the first and the second. Arranging in powers of  $a$  we have

$$4a^2 + 4a(3b - c) + 9b^2 - 6bc + c^2;$$

or

$$4a^2 + 4a(3b - c) + (3b - c)^2.$$

The required square root is therefore  $2a + (3b - c)$ , i.e.,  $2a + 3b - c$ .

Thus, however many terms an expression has, we can write down its square root by inspection, provided that the expression involves some particular letter in two powers only.

110. To find the square root of any algebraical expression we use the same principle as in Arithmetic [page 1439, Article 142]; that is, from the given expression we first subtract the square of a monomial, then we complete the subtraction of the square of a binomial whose first term is the term already used. Next we complete the subtraction of the square of the trinomial of which the first two terms form the binomial already used. And so on, until there is no remainder. The required square root is the expression whose square we have subtracted from the given expression. Now

$$(a + b)^2 = a^2 + 2ab + b^2 = a^2 + b(2a + b).$$

Therefore, in order to subtract  $(a + b)^2$ , we first subtract  $a^2$ , and then subtract the product

## MATHEMATICS

of  $(2a + b)$  and  $b$ . It is now clear that, given  $a^2 + 2ab + b^2$ , we can find the terms  $a$  and  $b$  of the square root. Thus

$$\begin{array}{r} a^2 + 2ab + b^2(a + b) \\ \underline{a^2} \phantom{+ 2ab + b^2} \\ 2a + b) \phantom{+ 2ab + b^2} \\ \underline{2ab + b^2} \phantom{+ 2ab + b^2} \\ 0 \phantom{+ 2ab + b^2} \end{array}$$

**EXPLANATION.** The square root,  $a$ , of the first term gives the first term of the required square root. Subtract the square of  $a$ , and the remainder is  $2ab + b^2$ . To get the second term of the root we take twice the term already found, i.e.  $2a$ , and divide it into the first term,  $2ab$ , of the remainder. This gives  $b$  for the second of the square root. Adding this to the  $2a$ , we get  $2a + b$ , the expression we have shown had to be multiplied by  $b$  and subtracted from the remainder, in order to complete the subtraction of  $(a + b)^2$ . On subtracting  $(2a + b)$  multiplied by  $b$ , we have no remainder, so that  $a + b$  is the square root of the expression  $a^2 + 2ab + b^2$ .

111. We shall now apply the method to one or two examples.

**Example 1.** Find the square root of

$$x^4 - 6x^3 + 11x^2 - 6x + 1.$$

First see that the expression is arranged in ascending or descending powers of  $x$ .

$$\begin{array}{r} x^4 - 6x^3 + 11x^2 - 6x + 1(x^2 - 3x + 1) \text{ Ans.} \\ \underline{x^4} \phantom{- 6x^3 + 11x^2 - 6x + 1} \\ 2x^2 - 3x \phantom{+ 1} \\ \underline{2x^2 - 6x + 1} \\ -6x^3 + 11x^2 - 6x + 1 \\ \underline{-6x^3 + 9x^2} \phantom{- 6x + 1} \\ 2x^2 - 6x + 1 \\ \underline{2x^2 - 6x + 1} \\ 0 \end{array}$$

**EXPLANATION.** The square root of  $x^4$  is  $x^2$ . This is the first term of the answer. Subtract the square of  $x^2$  from the given expression. The remainder is  $-6x^3 + 11x^2 - 6x + 1$ . Double  $x^2$ , the term already found; this gives  $2x^2$ . The second term of the root is found by dividing  $2x^2$  into  $-6x^3$ , the first term of the remainder. Hence the second term of the root is  $-3x$ . Put  $-3x$  in the answer, and also write  $-3x$  after the  $2x^2$  in the divisor. Multiply  $2x^2 - 3x$  by  $-3x$ , and subtract. We have now completed the subtraction of  $(x^2 - 3x)^2$ . The remainder is  $2x^2 - 6x + 1$ .

Repeat the process; that is, double  $x^2 - 3x$ , the part of the root already found. This gives  $2x^2 - 6x$ , and on dividing the first term of the remainder, viz.,  $2x^2$ , by the first term of  $2x^2 - 6x$ , we get 1 for the third term of the root. Write 1 in the answer, and also after  $2x^2 - 6x$  in the divisor. Multiply  $2x^2 - 6x + 1$  by 1 and subtract. This completes the subtraction of  $(x^2 - 3x + 1)^2$ . There is now no remainder. Hence the given expression must be equal to  $(x^2 - 3x + 1)^2$ , i.e., its square root is  $x^2 - 3x + 1$ .

**Example 2.** Find the square root of

$$4x^4 + \frac{4}{x^4} - 4x^2 + \frac{4}{x^2} - 7.$$

The expression arranged in descending powers of  $x$  is  $4x^4 - 4x^2 - 7 + \frac{4}{x^2} + \frac{4}{x^4}$ . The reason that

this is so will be seen in the section on Indices. The work is the same as for Example 1.

$$\begin{array}{r} 4x^4 - 4x^2 - 7 + \frac{4}{x^2} + \frac{4}{x^4} \left( 2x^2 - 1 - \frac{2}{x^2} \right) \text{ Ans.} \\ \underline{4x^4} \phantom{- 4x^2 - 7 + \frac{4}{x^2} + \frac{4}{x^4}} \\ -4x^2 - 7 \phantom{+ \frac{4}{x^2} + \frac{4}{x^4}} \\ \underline{-4x^2 - 7} \phantom{+ \frac{4}{x^2} + \frac{4}{x^4}} \\ 0 \phantom{+ \frac{4}{x^2} + \frac{4}{x^4}} \end{array}$$

Notice that it is not necessary to write down every term of the remainder at each stage, as was done in Example 1.

## EXAMPLES 31

Find the square roots of

1.  $a^2 - 2ab + 4ac + b^2 - 4br + 4r^2$ .
2.  $a^2 + 2ab + (b^2 - 4ac)x^2 - 4brx^3 + 4c^2x^4$ .
3.  $\frac{x^4}{36} + \frac{x^3}{9} - \frac{2x^2}{9} - \frac{2x}{3} + 1$ .
4.  $12x^3 - 4x^4 + 9 - 6x + x^2 + 4x^6$ .
5.  $x^4 - 2x^3y + 5x^2y^2 - 4xy^3 + 4y^4$ .
6.  $\frac{25}{x^2} - 12x + \frac{16}{x^3} + 4x^4 - \frac{24}{x}$ .

## FRACTIONAL AND NEGATIVE INDICES

112. Up to the present, any index we have used has been a positive whole number. For, from the definition, the index shows the number of letters which are multiplied together to give some particular power.

It is now necessary to extend the meaning of  $a^n$  so as to include values of  $n$  which are either fractional or negative.

Now, when  $m$  and  $n$  are positive integers, we know that

$$a^m = a \cdot a \cdot a \cdot \dots \text{to } m \text{ factors,}$$

and

$$a^n = a \cdot a \cdot a \cdot \dots \text{to } n \text{ factors.}$$

Therefore,

$$\begin{aligned} a^m \times a^n &= (a \cdot a \cdot a \cdot \dots \text{to } m \text{ factors}) \times (a \cdot a \cdot a \cdot \dots \text{to } n \text{ factors}) \\ &= a \cdot a \cdot a \cdot \dots \text{to } (m + n) \text{ factors} \\ &= a^{m+n}. \end{aligned}$$

This is the fundamental index law.

It follows that

$$a^m \times a^n \times a^p = a^{m+n+p} \text{ or } a^m \times a^n = a^{m+n},$$

and so on, however many powers of  $a$  may be multiplied together. Again,

$$\begin{aligned} (a^m)^n &= a^m \cdot a^m \cdot a^m \cdot \dots \text{to } n \text{ factors} \\ &= a^{m+n} \text{ or } a^{mn}, \text{ by what has just been proved,} \\ &= a^{mn}. \end{aligned}$$

Also

$$\begin{aligned} (ab)^m &= ab \times ab \times ab \dots \text{to } m \text{ factors} \\ &= (a \cdot a \cdot a \cdot \dots \text{to } m \text{ factors}) \\ &\quad \times (b \cdot b \cdot b \cdot \dots \text{to } m \text{ factors}); \text{ since the factors of a product may be taken in any order} \\ &= a^m \times b^m. \end{aligned}$$

Similarly,

$$(abc \dots)^m = a^m \times b^m \times c^m \times \dots$$

Thus, the  $m$ th power of a product is equal to the product of the  $m$ th powers of the factors.

We have now proved that

$a^m \times a^n = a^{m+n}$ ,  $(a^m)^n = a^{mn}$ , and  $(ab)^m = a^m \cdot b^m$  when  $m$  and  $n$  are positive integers.

**113.** In order to find a meaning for  $a^n$  when  $n$  is not a positive integer we assume that the meaning must be such that the fundamental index law is always true, i.e., we assume that whatever values  $m$  and  $n$  may have, the meaning of  $a^m$  and  $a^n$  is such that  $a^m \times a^n = a^{m+n}$ .

For example, the meaning of  $a^{\frac{1}{3}}$  must be such that

$$a^{\frac{1}{3}} \times a^{\frac{1}{3}} \times a^{\frac{1}{3}} = a^{\frac{1}{3} + \frac{1}{3} + \frac{1}{3}} = a^1 = a.$$

Hence  $a^{\frac{1}{3}}$  must mean the quantity whose cube is  $a$ ; i.e.,  $a^{\frac{1}{3}}$  means  $\sqrt[3]{a}$ .

**114.** To find a meaning for  $a^{\frac{m}{n}}$ , where  $m$  and  $n$  are positive integers.

Since we have assumed that the index law is always true, we must have

$$\begin{aligned} a^{\frac{m}{n}} \times a^{\frac{m}{n}} \times a^{\frac{m}{n}} \times \dots \text{to } n \text{ factors} \\ = a^{\frac{m}{n} + \frac{m}{n} + \frac{m}{n} + \dots \text{to } n \text{ terms}} \\ = a^m = a^m. \end{aligned}$$

Thus,  $a^{\frac{m}{n}}$  is the quantity which, raised to the  $n$ th power, gives  $a^m$ . That is,  $a^{\frac{m}{n}}$  is the  $n$ th root of  $a^m$ ; or

$$a^{\frac{m}{n}} = \sqrt[n]{a^m}.$$

For example,

$$\begin{aligned} a^{\frac{1}{3}} &= \sqrt[3]{a} \\ 9^{\frac{1}{3}} &= \sqrt[3]{9} = \sqrt[3]{27} = 3. \end{aligned}$$

**115.** To find a meaning for  $a^0$ .

By the index law we know that

$$a^0 \times a^n = a^{0+n} = a^n.$$

Dividing both sides by  $a^n$ , we get

$$a^0 = a^n : a^n = 1.$$

Hence, any quantity raised to the power 0 is 1. [See Article 39, page 2151.]

**116.** To find a meaning for  $a^{-n}$ , where  $n$  has any positive value.

By the index law

$$a^{-n} \times a^n = a^{-n+n} = a^0 = 1. \quad [\text{Art. 115.}]$$

Therefore, dividing both sides by  $a^n$ , we have

$$a^{-n} = \frac{1}{a^n}.$$

For example,

$$8^{-\frac{1}{3}} = \frac{1}{8^{\frac{1}{3}}} = \frac{1}{\sqrt[3]{8}} = \frac{1}{2} = \frac{1}{2^1} = \frac{1}{16}.$$

**117.** By assuming that the index law  $a^m \times a^n = a^{m+n}$  is always true, we have found that  $a^n$  has an intelligible meaning, whatever the value of  $n$  may be. We have now to show that, with these meanings,

$a^m \times a^n = a^{m+n}$ ,  $(a^m)^n = a^{mn}$ , and  $(ab)^m = a^m b^m$  are true for all values of  $m$  and  $n$ , and not

merely when  $m$  and  $n$  are positive integers, as in Article 112.

(A.) To prove that  $a^m \times a^n = a^{m+n}$  for all values of  $m$  and  $n$ .

We have already proved the case in which  $m$  and  $n$  are positive integers.

Next, let  $m$  and  $n$  be positive fractions,  $m$  being equal to  $\frac{p}{q}$ , and  $n$  to  $\frac{r}{s}$ . Then,

$$\begin{aligned} a^m \times a^n &= a^{\frac{p}{q}} \times a^{\frac{r}{s}} \\ &= a^{\frac{ps}{qs}} \times a^{\frac{qr}{qs}} \\ &= \sqrt[qs]{a^{ps}} \times \sqrt[qs]{a^{qr}} \quad [\text{Art. 114}] \\ &= \sqrt[qs]{a^{ps} \cdot a^{qr}} = \sqrt[qs]{a^{ps+qr}} \\ &= a^{\frac{ps+qr}{qs}} = a^{\frac{ps}{qs} + \frac{qr}{qs}} = a^{\frac{p}{q} + \frac{r}{s}}. \end{aligned}$$

Again, when  $m$  and  $n$  are positive, we have

$$a^{-m} \times a^{-n} = \frac{1}{a^m} \times \frac{1}{a^n} = \frac{1}{a^{m+n}} = a^{-(m+n)}.$$

And, if  $m$  is greater than  $n$ , so that  $m-n$  is positive, we have

$$a^{m-n} \times a^n = a^{m-n+n} = a^m.$$

But

$$a^{m-n} \times a^{-n} \times a^n = a^{m-n+n} = a^m.$$

Therefore,

$$a^{m-n} = a^m \times a^{-n}.$$

Finally, if  $m$  is less than  $n$ , so that  $m-n$  is negative,

$$\frac{1}{a^{-m-n}} \times \frac{1}{a^n} = \frac{1}{a^{m+n}}$$

by the case just proved; i.e.,

$$a^{m-n} \times a^{-n} = a^{m-n-n} = a^{m-2n}.$$

Thus, we have proved that  $a^m \times a^n = a^{m+n}$ .

(i.) When  $m$  and  $n$  are positive integers.

(ii.) When  $m$  and  $n$  are positive fractions.

(iii.) When  $m$  and  $n$  are both negative.

(iv.) When one is positive and the other negative.

Hence,

$$a^m \times a^n = a^{m+n}$$

is true for all values of  $m$  and  $n$ .

NOTE. Since the law is true for all values of the indices, we have

$$a^{m-n} \times a^n = a^{m-n+n} = a^m.$$

Therefore,

$$a^m = a^{m-n} \times a^n$$

for all values of  $m$  and  $n$ .

(B.) To prove that  $(a^m)^n = a^{mn}$  for all values of  $m$  and  $n$ .

First, let  $n$  be a positive integer. Then, whatever be the value of  $m$ , we know from (A) that

$$\begin{aligned} (a^m)^n &= a^m \cdot a^m \cdot a^m \dots \text{to } n \text{ factors} \\ &= a^{m+m+m+\dots \text{to } n \text{ terms}} \\ &= a^{mn}. \end{aligned}$$

Next, let  $n$  be a positive fraction, equal to  $\frac{r}{s}$ , where  $p$  and  $q$  are positive integers. Then

$$\begin{aligned} (a^m)^n &= (a^{\frac{p}{q}})^{\frac{r}{s}} = \sqrt[s]{(a^{\frac{p}{q}})^r} \\ &= \sqrt[s]{a^{\frac{pr}{q}}}, \text{ since } p \text{ is a positive integer} \\ &= a^{\frac{mpr}{qs}} \\ &= a^{mn}. \end{aligned}$$

# MATHEMATICS

Again, let  $n$  be negative, and equal to  $-p$ . Then

$$(a^m)^n = (a^m)^{-p} = \frac{1}{(a^m)^p} \text{ [Art. 116]}$$

$$= \frac{1}{a^{mp}}$$

$$= a^{-mp} = a^{mn}.$$

Hence,  $(a^m)^n = a^{mn}$  whatever values  $m$  and  $n$  may have.

(C.) To prove that  $(ab)^m = a^m b^m$  for all values of  $m$ .

The case in which  $m$  is a positive integer was proved in Article 112.

Let  $m$  be a positive fraction, equal to  $\frac{p}{q}$ . Then,

$$(ab)^m = (ab)^{\frac{p}{q}}$$

$$= \sqrt[q]{(ab)^p}$$

$$= \sqrt[q]{a^p b^p}, \text{ since } p \text{ is a positive integer.}$$

And,

$$(a^m b^m)^q = a^{mq} \cdot b^{mq}, \text{ since } q \text{ is a positive integer}$$

$$= a^p \cdot b^p;$$

so that

$$a^m b^m = \sqrt[q]{a^p b^p}.$$

Thus, since

$(ab)^m$  and  $a^m b^m$  are each equal to  $\sqrt[q]{a^p b^p}$  we have

$$(ab)^m = a^m b^m.$$

Finally, if  $m$  be negative, equal to  $-r$ , say, then,

$$(ab)^m = (ab)^{-r} = \frac{1}{(ab)^r} = \frac{1}{a^r b^r} = a^{-r} b^{-r} = a^m b^m.$$

Thus  $(ab)^m = a^m b^m$  for all values of  $m$ .

118. Having proved our three formulæ for all values of the indices, we see that quantities involving fractional or negative indices can be treated exactly as if the indices were positive  $(2x^{\frac{2}{3}} - 14x^{-1} + x^{-2})$  integers.

The following examples illustrate the principles we have been investigating.

Example 1. Find the value of

$$\left(\frac{64}{125}\right)^{\frac{2}{3}}$$

$$\left(\frac{64}{125}\right)^{-\frac{2}{3}} = \frac{125^{\frac{2}{3}}}{64^{\frac{2}{3}}} = \left(\frac{125^{\frac{1}{3}}}{64^{\frac{1}{3}}}\right)^2$$

$$= \left(\frac{\sqrt[3]{125}}{\sqrt[3]{64}}\right)^2$$

$$= \left(\frac{5}{4}\right)^2 = \frac{25}{16} \text{ Ans.}$$

Example 2. Simplify

$$\left(\frac{x^{-3}y}{x^4y^{-2}}\right)^2 + \left(\frac{xy^{-2}}{x^3y}\right)^3.$$

Given expression

$$= (x^{-3}y^{1-(-2)})^{-2} + (x^{1-(-3)}y^{-2-1})^3$$

$$= (x^{-7}y^3)^{-2} + (x^4y^{-3})^3$$

$$= x^{14}y^{-6} + x^{12}y^{-9}$$

$$= x^{14-12}y^{-6-(-9)} = x^2y^3 \text{ Ans.}$$

After a little practice we can omit all the intermediate steps, and write down the indices of  $x$  and  $y$  at once. We have only to remember that to multiply two powers of  $x$  we add the indices, to divide two powers we subtract the indices, and to raise a power to a power we multiply the indices. The entire working would appear as follows:

Given expression

$$= x^{14-12}y^{-6-(-9)} = x^2y^3 \text{ Ans.}$$

Example 3. Multiply

$$x^{\frac{2}{3}} - x^{\frac{1}{3}}y^{\frac{1}{3}} + y^{\frac{2}{3}} \text{ by } x^{\frac{1}{3}} + y^{\frac{1}{3}}.$$

$$x^{\frac{2}{3}} - x^{\frac{1}{3}}y^{\frac{1}{3}} + y^{\frac{2}{3}}$$

$$x^{\frac{1}{3}} + y^{\frac{1}{3}}$$

$$x^{\frac{2}{3}} - x^{\frac{1}{3}}y^{\frac{1}{3}} + x^{\frac{1}{3}}y^{\frac{1}{3}}$$

$$+ x^{\frac{2}{3}}y^{\frac{1}{3}} - x^{\frac{1}{3}}y^{\frac{2}{3}} + y^{\frac{2}{3}}$$

$$\hline x^{\frac{2}{3}} + y^{\frac{2}{3}} \text{ Ans.}$$

Arrange the work as in ordinary multiplication. First multiply by  $x^{\frac{1}{3}}$ . We have

$$x^{\frac{2}{3}} \times x^{\frac{1}{3}} = x^{\frac{2}{3}+\frac{1}{3}} = x^1 = x,$$

and so on.

Example 4. Find the square root of

$$x^4 - 14x^{\frac{3}{2}} + 49 - 2x^{-\frac{1}{2}} - 14x^{-1} + x^{-2}.$$

The expression is already arranged in descending powers of  $x$ . Proceed as in Article 111, remembering that to get the square root of a power of  $x$  we must halve the index, so that the square root of  $x^4$  is  $x^2$ , and so on.

$$x^4 - 14x^{\frac{3}{2}} + 49 + 2x^{-\frac{1}{2}} - 14x^{-1} + x^{-2} \left( x^2 - 7 + x^{-1} \right) \text{ Ans.}$$

$$2x^{\frac{3}{2}} - 7$$

$$- 14x^{\frac{5}{2}} + 49$$

$$- 14x^{\frac{3}{2}} + 49$$

$$2x^{-\frac{1}{2}} - 14x^{-1} + x^{-2}$$

$$2x^{-\frac{1}{2}} - 14x^{-1} + x^{-2}$$

## EXAMPLES 32

Find the value of

$$1. 27^{\frac{2}{3}}.$$

$$3. 8^{\frac{3}{4}}.$$

$$2. 9^{\frac{1}{2}}.$$

$$4. \left(\frac{9}{16}\right)^{\frac{3}{4}}.$$

Simplify

$$5. (x^{\frac{1}{2}}y^{-\frac{3}{4}})^3.$$

$$6. x^{\frac{1}{3}} \times x^{-\frac{1}{2}} \times x^{\frac{7}{6}}$$

$$7. (x^6)^2 \times (x^6)^2 \times (x^{-6})^2.$$

$$8. (x^{-2}y)^{-3} \times (x^{-3}y^2)^5.$$

$$9. \text{ Multiply } 2x^{\frac{2}{3}} - 3x^{\frac{1}{2}}y^{\frac{2}{3}} + y \text{ by } x + x^{\frac{1}{2}}y^{\frac{1}{3}} - y^{\frac{2}{3}}.$$

$$10. \text{ Divide } x + 1 \text{ by } x^{\frac{1}{2}} + 1.$$

$$11. \text{ Find the square root of } 25x^2 - 12x + 16x^{-4} + 4x^4 - 24x^0.$$

$$12. \text{ Find the square root of } 4x^4 + 4x^{-4} - 4x^2 + 4x^{-2} - 7.$$

$$13. \text{ Square } x^{\frac{1}{2}} - 1 - x^{-\frac{1}{2}}.$$

# Answers to Algebra

## EXAMPLES 28

1. 3 or -5.
2. 5 or 21.
3.  $\frac{1}{5}$  or  $\frac{5}{3}$ .
4.  $\frac{1}{5}$  or  $\frac{1}{3}$ .
5.  $\frac{a}{\beta} + \frac{\beta}{a} = \frac{a^2 + \beta^2}{a\beta} = \frac{(a+\beta)^2 - 2a\beta}{a\beta} = \frac{p^2 - 2q}{q}$ .
6.  $\frac{1}{a^3} + \frac{1}{\beta^3} = \frac{a^3 + \beta^3}{a^3\beta^3} = \frac{(a+\beta)(a^2 - a\beta + \beta^2)}{a^3\beta^3} = \frac{p(p^2 - 3q)}{a^3\beta^3}$   
 $= \frac{(a+\beta)(a^2 + \beta^2 - 3a\beta)}{a^3\beta^3} = \frac{p(p^2 - 3q)}{a^3\beta^3}$   
 $= \frac{(p^2 - q)\sqrt{p^2 - 4q}}{a^2\beta^2}$
7.  $\frac{a}{\beta} - \frac{\beta}{a} = \frac{a^2 - \beta^2}{a^2\beta^2} = \frac{(a-\beta)(a+\beta)}{a^2\beta^2} = \frac{p(p^2 - 3q)}{a^2\beta^2}$   
 $= \frac{(p^2 - q)\sqrt{p^2 - 4q}}{a^2\beta^2}$

8.  $2x^2 - 4x + 3 = 0$ .

9. Let  $a, \beta$  be the roots of  $x^2 + px + q = 0$ . Then the roots of  $x^2 + p^2x + q^2 = 0$  are to be  $a^2$  and  $\beta^2$ . Hence, by Article 100 we have four equations  $a + \beta = -p, a\beta = q, a^2 + \beta^2 = -p^2, a^2\beta^2 = q^2$ . The second and fourth of these are identical, so that we are left with three equations from which to eliminate the two unknown quantities  $a, \beta$ . Now, since  $a^2 + \beta^2 = (a + \beta)^2 - 2a\beta$ , we have, from the three equations  $-p^2 = p^2 - 2q$ , or  $p^2 = q$ , which is the required condition.

## EXAMPLES 29

1.  $x = 4, y = 2$ , or  $x = 2, y = 4$ .
2.  $x = 5, y = 3$ , or  $x = -3, y = -5$ .
3.  $x = 7, y = 5$  or  $x = -7, y = -5$ .
4.  $x = 4, y = 1$ , or  $x = -1, y = -4$ .
5.  $x = 6, y = 1$ , or  $x = -1, y = -6$ . The question should read  $x^2 - y^2 = 215$ .
6.  $x = \pm 3, y = \pm 2$ ; or  $x = \pm \frac{5}{\sqrt{2}}, y = \pm \frac{1}{\sqrt{2}}$ .
7.  $x = 5, y = 2$ , or  $x = \frac{13}{3}, y = \frac{14}{9}$ .
8.  $x = 4, y = 3$ , or  $x = \frac{34}{5}, y = -\frac{27}{5}$ .

## EXAMPLES 30

1. 13 and 17.
2. If  $x =$  the smaller number, then  $x + 1 =$  the other. Hence,  $\frac{1}{x} + \frac{1}{x+1} = \frac{23}{132}$ , giving  $x = 11$  or  $-\frac{12}{23}$ . Therefore the two numbers are 11 and 12.
3. Let  $x =$  number of yards. Then  $\frac{50}{x} =$  price per yard in shillings. If the price were 10d. less, i.e.,  $(\frac{50}{x} - \frac{5}{6})$  shillings per yard, he

would get  $50 + (\frac{50}{x} - \frac{5}{6})$  yards for the same money. Hence,  $x + 3 = \frac{50}{\frac{50}{x} - \frac{5}{6}}$ , or  $x + 3 = \frac{60x}{60 - x}$ , whence,  $x = 12$  or  $-15$ . Therefore, he bought 12 yards for 50s., i.e., 12 yards at 4s. 2d. per yard.

4.  $x$  yards = the length. Then  $(x - 5)$  yards = breadth. Therefore,  $x(x - 5) = 6,750$ , whence,  $x = 90$  yards.

5. If  $x$  miles per hour = rate of train, then  $\frac{200}{x} =$  number of hours taken.

Similarly,  $\frac{200}{x+1} =$  number of hours when the rate is  $x + 1$ . This is  $\frac{1}{15}$  of an hour less than the first time. Therefore,  $\frac{200}{x} - \frac{200}{x+1} = \frac{4}{15}$ , from which  $x = 27\frac{1}{2}$  or  $-28\frac{1}{2}$ . Thus the rate is  $27\frac{1}{2}$  miles per hour.

6. Let  $\frac{x}{y}$  be the proper fraction. Then  $x$  must be less than  $y$ . We have the two equations  $2y - x^2 - 9$  and  $y^2 - x^2 = 264$ . Hence, by subtraction,  $y^2 - 2y - 255 = 0$ ; so that  $y = 17$  or  $-15$ . The denominator is therefore 17, the numerator is  $\sqrt{34 - 9}$ , or 5. Hence, the fraction is  $\frac{5}{17}$ .

7.  $1\frac{1}{2}$  acres = 8,470 square yards. Let  $x$  yards = length,  $y$  yards = breadth. Then  $xy = 8,470$ , and  $(x + 11)(y - 7) = 8,470$ . Subtract the first equation from the second, then  $11y - 7x - 77 = 0$ . Find  $x$  in terms of  $y$  from this, and substitute in  $xy = 8,470$ . The solution is 110 yards length, 77 yards breadth.

8. Let  $x$  be the smaller number. Then  $(x + 1)^3 - x^3 = 724$ , whence,  $x = 15$  or  $-16$ . Thus, the numbers are 15 and  $15 + 1$ , i.e., 15 and 16.

9. Let  $x$  shillings per dozen be the original price. Then  $\frac{20}{x} =$  number of dozens for £1.

Similarly,  $\frac{20}{x+2} =$  number of dozens for £1 when the price is raised. This is half dozen less than in former case. Hence,  $\frac{20}{x} - \frac{20}{x+2} = \frac{1}{2}$ , or  $x^2 + 2x - 80 = 0$ , whence,  $x = 8$  or  $-10$ . Required price therefore is 8s. per dozen.

10. Let  $x$  miles per hour = slow train's rate. Then  $x + 15 =$  other's rate. Their times, to go 63 miles, are  $\frac{63}{x}$  hours and  $\frac{63}{x+15}$  hours. Hence,  $\frac{63}{x} - \frac{63}{x+15} = \frac{42}{60}$ , whence,  $x = 30$  or  $-45$ . The required rates are therefore 30 miles per hour and  $30 + 15$ , or 45 miles per hour.

Continued

# BRANCH AND COST ACCOUNTS

Profits of Departments and Branches. Branch Books. Manufacturers' Cost Sheets. Stores. Plant. Establishment Expenses. Contractors' Accounts

By J. F. G. PRICE

MANY wholesale and retail trading concerns have distinct departments, each working independently of the others. Where this is the case it is necessary for the proprietors to know, not only the result of the trading as a whole, but also the results of the operations of the separate departments. The reason for this is that while a general profit and loss account might show that the whole business was being carried on at a profit, it would not disclose what might be the fact—viz., that this was owing to one or two departments earning good profits, while others were being carried on at a loss.

**Departmental Accounts.** A system of accounts has, therefore, to be formulated which will show, not only the general result, but also the profit or loss on each department. To achieve this, a separate trading account for each department must be prepared, and the best method of doing this is to so arrange the books of original entry that the information required for the purpose is readily available. In a business such as is now being considered, it is usually sufficient for the object in view to ascertain only the gross profit on each department, leaving general establishment expenses to be debited to a general profit and loss account. If it is desired to arrive at the actual net profit of each, a simple method is to charge the departments with a percentage of the general expenses, such as rent, rates, lighting, counting-house salaries, etc., such percentage being based either upon the amount of wages paid or the amount of turnover.

The case of a business will be taken having four departments—viz., mantles, dress materials, felts, and trimmings. The first step is to so arrange the purchases book that it shows the amount of goods bought for each department as well as the total. This object can be attained by having separate purchases books for each department, but it is generally found more convenient to have one book only, ruled in the following form, with such modifications as may be required by the particular business for which it is used:

| Date. | Invoice No. | Name. | It Lcd Folio. | Total of Invoice. | Mantles. | Dress Materials. | Felts. | Trimmings. |
|-------|-------------|-------|---------------|-------------------|----------|------------------|--------|------------|
|       |             |       |               |                   |          |                  |        |            |

The amount of the invoices will be posted to the credit of 'the sellers' accounts in the bought ledger in the ordinary way, while the totals of the columns relating to the four departments

will be respectively posted to the debit of an account opened in the general ledger for each department. The salaries and wages book will be ruled in such a manner as to show the amount paid to the employees in each department separately, or else the book must be dissected monthly. Whichever course is adopted the amount attributable to each department must be posted to the debit of the respective departmental accounts.

**Departmental Sales.** With regard to sales, separate books will be required for cash and credit sales, and the method of keeping them necessarily differs. The cash sales will be made over the counter, and salesmen will be allocated to the various departments. Each salesman will have his own book, in which he will make out a bill for each transaction, which may, in some instances, include goods from all the departments. The books will contain the bill forms in duplicate, in order that carbon copies may be taken. The original bill is receipted and handed to the customer, and the duplicate is sent to the cashier. At the end of the day each salesman's cash must agree with the total of his duplicate bills in the possession of the cashier. In many firms the money received from the customer is handed at once to the cashier, with the original and duplicate bills. He receipts the former, which is handed to the customer, while the latter is retained with the cash. The salesman's duplicates are entered by the cashier in the cash sales book, which is ruled with columns for each department and for the total.

If the number of transactions justify it, a separate page will be set apart for each salesman. The columns will be totalled daily, and the cashier must agree his total cash received with the total of the sales during the day. At the end of the month the daily totals of the departmental columns are extracted, and their aggregates posted to the credit of the departmental accounts in the general ledger.

The credit sales will be dealt with in the same manner as in a business where there are no departmental accounts, except that the sales

books will be ruled with columns for the various departments in the same way as in the case of the purchases book. The totals of the columns will be posted monthly to the credit of the

departmental accounts in the general ledger, while the separate items are posted daily to the debit of customers in the sold ledger.

### Departmental Trading Accounts.

The results of the posting of the original books in this manner will be that separate trading accounts for the various departments will exist in the books, while the trading account of the business as a whole can be made out in the form shown here.

The preparation of the trading account in this form enables the proprietor to see at a glance, not only the gross profit of the whole business, but also that of the separate departments. The result is that a failure by any department to earn the rate of profit which may reasonably be expected is disclosed. In the case with which we are dealing it is apparent that there is something wrong with the felts department. The mischief is in either the stock, purchases, or sales. Stock may have been taken too high at the end of the last trading period, or too low now. If it is neither of these things, then the department may have been buying too dear, or selling too cheap. The system of accounts has done its duty and disclosed the existence of the defect. It is for the proprietor to discover the cause and the remedy.

### Branch Accounts.

The reason which renders the keeping of departmental accounts desirable applies with even greater force to branch accounts. It scarcely needs stating that the proprietor of a business with several branches requires to know the result of the

trading at each of them. The methods of keeping the accounts of branches differ according to the requirements of the business; but there are general principles which can be observed in every case. Let us assume that a branch has been opened and a manager installed. A quantity of goods, and a supply of cash for petty expenses, are sent by the head office to the branch, where a set of books will be kept in which entries will be made recording those facts. The goods and cash accounts in the branch ledger will be debited with the value received, and an account opened for the head office will be credited. All goods and cash received from the head office during the year will be similarly treated; while, if the manager is authorised to purchase goods himself for the branch, he will debit goods account with the amount purchased and credit the sellers.

### Branch and Head Office Returns.

All the cash received for sales must be banked daily, and weekly returns of all business done sent to the head office every Monday morning. If sales are allowed on credit, details must be furnished to the head office, as it is usual for accounts to be rendered from there. If cash is received by the head office from branch debtors, the branch must be notified in order that the amounts received may be credited to the customers, the head office, of course, being debited with the amounts as the receipt of them is notified. Payments to creditors for goods supplied to the branch direct will probably be rare, and will, as a rule, be made by the head office. This will render necessary entries in the branch ledger, debiting the creditors with the amounts they receive, and crediting head office account with the amount paid for the branch. The result will be that the head office is credited with all goods and cash supplied to the branch, and with payments made on its behalf, while it is debited with all cash paid into the bank, and with all amounts received from debtors for goods supplied by the branch.

**Head Office Entries.** In the head office books the entries will be the reverse of those in the branch ledger. All goods and cash supplied will be debited to an account opened in the name of the branch, the cash and goods accounts, of course, being credited. Any goods returned by the branch will be debited to goods and credited to the branch. Payments made for the branch will be debited to the branch office account and credited to cash, while amounts received by the head office for the branch will be debited to cash and credited to the branch account.

At the end of the trading year a trial balance of the branch ledger will be prepared by the manager. It will contain in the debit column the balances of wages, purchases, discounts, cash and any expenses accounts, as well as the customers' balances; while on the credit side will appear sales and creditors' balances. The balance of the head office account will also appear in one of the columns. This trial balance will be sent to the head office, and, if the balance of the head office account shown therein agrees

with the balance of the branch account as appearing in the head office ledger, a trading account of the branch will be prepared and the balance thereof transferred to the head office account in the branch ledger. If the result is a profit, it will be entered on the credit side of the account; if a loss, on the debit side.

The reason for the agreement of the two accounts in the respective books should be apparent, but in order to make the matter quite clear the summarised accounts are given on the next page.

If there are any fixed assets of the branch, such as lease, fixtures, furniture, etc., they are not included in the branch ledger, but are debited to their respective accounts in the head office ledger. When the balance-sheet of the business as a whole is prepared, they are included therein with other assets of a like nature. The floating assets of the branch, consisting of debtors' stock and cash, are also incorporated with similar assets belonging to the head office and to other branches, and are brought into the general balance-sheet instead of being shown as a debit balance owing by the branch to the head office.

**Cost Accounts.** It is necessary in all businesses having for their object the manufacture or production of commodities that there shall be an efficient system of accounts enabling the proprietor to arrive at the cost of the article produced. The main cause from which this necessity arises is that the manufacturer must know the cost of what he produces in order that he may fix a price at which to sell, or to give an estimate for a contract for similar work in future. There are two principal classes of

undertaking in which a system of cost accounts is of the utmost importance—*viz.*, (1) those engaged in the production of a particular article, *e.g.*, collieries, ironworks, brickworks, etc.; (2) those in which the business consists of the carrying out of a definite piece of work, known as a contract, where knowledge of the actual cost of each contract is required.

For both classes of undertaking the general principles to be observed are the same, and consist of the careful subdivision of the various heads over which the cost of performing the work is spread. In both kinds of business the cost of the finished article or of the contract is made up of (1) materials, (2) labour, (3) general expenses necessarily incurred in carrying on the business, including wear and tear of machinery and plant in producing the article or executing the contract. The records to be kept in order to obtain the desired result necessarily vary in different businesses. In a manufacturing concern, where one class of article is produced, the cost account is in the nature of the debit side of a trading account for a limited period, frequently a week or a month; while in the case of a contractor a separate cost account is kept for each contract undertaken. In the former class, however, the items are more highly classified than in the trading account of an ordinary business.

**Manufacturing Cost.** The wages paid are analysed over the different classes of workmen or according to the various stages of the work, and the cost of supervision directly attributable to the performance of the work is also included. The materials and stores used are charged at cost, and a charge is also

made for what may be termed Indirect Expenses, or, as they are usually called, Establishment Expenses. These consist of the depreciation naturally arising from the continual using of the machinery and plant in the production of the article, and also of the cost of upkeep of the business apart from the direct cost of manufacture or production. They include rent, rates and taxes of the factory and workshop, the salaries of the factory managers, and the cost of motive power. Many businesses draw a line here, while others add general office expenses, discounts, bad debts, commissions, etc., before arriving at a figure which is deemed to be the cost.

In this class of business this periodical summary is generally called a *cost sheet*, and gives a comparison between the current month and the preceding one. In the case of collieries, brickworks, etc., a statement is added showing the cost per unit during the month. In a colliery the unit is the ton, in a brickworks, 1,000 bricks. Cost accounts or sheets on somewhat similar lines, but of a more elaborate nature, are also prepared in the case of tramway, gas, water, electric light and railway companies for the purpose of ascertaining the cost per unit.

For the purpose of making the figures required for the final cost account or summary easily obtainable, the subsidiary books must be suitably ruled. The wages book is kept in tabular form, and shows not only the amounts paid weekly for the different classes of labour, but also the amount which is attributable to each contract or department. Care must be taken to ensure that the amounts charged in the various cost sheets or contract accounts agree in total with the amount actually paid. It will sometimes be found that the whole of the wages paid cannot be allocated over the various processes or jobs. In such a case the balance of wages must be regarded as part of the general establishment expenses.

**Stores.** The detail which, as a rule, gives more trouble than any other in connection with cost accounts is that of stores—i.e., materials used in the process of manufacture of which a certain stock is kept on hand. The cause of the trouble is the difficulty in agreeing the amount of stores on hand at any time with the amount that should be there, having regard to the purchases and the amount used according to the cost sheets. The deficiency is to some

extent caused by waste, for it is impossible to take most kinds of stores into stock in bulk, and hand it out in small quantities without some shrinkage. But the chief danger is from leakage by pilfering, and to guard against it several devices have been adopted. One in very general use is that stores are only handed out by the storekeeper upon written requisitions signed by properly authorised persons. The requisitions state the purpose or contract for which the stores are required, and after the demand has been complied with they are sent by the storekeeper to the counting house, where the stores are charged out in accordance with the particulars given on the requisition.

The best way of ensuring that this is accurately done is to have a summary of the stores issued during a given period prepared in columnar form. The columns are headed with the name or number of the department, or contract, for which the stores are required, and at the end of the week or month the total of each column is posted to the debit of the cost account indicated. The stores are priced out at cost, and this step should be carefully checked, as improper pricing might open the door to considerable fraud. For this reason the pricing is better left to the counting-house staff than to anybody handling the stores.

**Stores Accounts.** In some establishments stores accounts of a more or less elaborate design are kept, showing both quantities and prices of stores received and issued. Where these are accurately kept—and there is no reason why, with care, they should not be—they are of considerable value in operating as a check upon the stores in hand. Even when the accounts under this system are properly kept, there will be differences, but they should be small in amount. If any great discrepancy were discovered between the stores appearing by the accounts to be in hand, and those actually in stock, as ascertained by stocktaking, searching inquiries would be made to ascertain the cause.

Any stores not required for the purpose for which they were issued are returned into stock, with a note of their quantity and the job from which they are returned. Separate accounts will, of course, be required for the various kinds of stores, and as it will be of assistance to the student in the proper understanding of the subject, a specimen ruling for an account is given hereunder:

**CLERKSHIP**

Most large contracts require that special materials shall be purchased for them. These materials do not pass through the stores accounts, but are charged to the contract accounts direct from the purchases book.

**Plant.** In the case of a contractor, the plant used on the works in progress will be dealt with in a similar manner to the stores, so far as charging it out to contracts or departments is concerned ; but it is not so usual to keep plant accounts as store accounts. A good method of recording the movements of plant is that mentioned above in connection with stores, by which it is only issued against proper requisitions, which are summarised periodically, and the totals charged out to the different jobs where the plant is being employed. In regard to plant, a point arises which also affects stores to a limited extent. When plant has been in use for perhaps several months on a contract, where it has been exposed to the weather, it naturally deteriorates in value, and is not worth as much when returned as it was when issued. The depreciation in value is made to fall against the contract by the plant being credited to the contract account at a lower rate than that at which it was originally charged. It thus goes back into stock at its diminished value.

**Contract Accounts.** It is convenient to keep the accounts of contracts in tabular form, in order that the expenditure under the various heads may easily be ascertained at any time. The headings will vary according to the nature of the business, and that given on this page is a useful form in the case of a builder.

When the contract is completed, the account is closed, as shown, by crediting the amount due from the person for whom the work has been carried out, and also the then value of any plant and stores returned. The difference between the two sides of the account is obviously the profit or loss upon the contract. The debit to the owner of the work is shown on an account in a ledger known as the contract ledger.

This ledger, being used for keeping the accounts of persons for whom work is being done, and who are, therefore, indebted to the business, it would naturally be supposed that the balances therein were debit balances. It usually happens, however, that payments on account of the work are made by the owners during the progress of the contract. When this is the case, the amounts received are debited to cash and credited to the payer in ordinary course. As the owners of the various works are not debited with the contract price until the completion of the contracts, it follows that their accounts in the meantime show credit balances, against which have to be set the several debits on the contracts accounts.

**Establishment Expenses.** The nature of establishment expenses has been explained, but nothing has yet been said upon the manner of apportioning them between the various jobs in the case of a contractor, or between the various departments or processes in a manufacturing concern. The practice upon this point differs, and it depends to some extent upon the nature of both the business and the particular expense. It will be sufficient for the present purpose to indicate the various systems, as no rule can be laid down for general application. There are three principal methods of charging the department or contract—viz. : (1) such a proportion of the total establishment expenses as the cost of the contract bears to the cost of all the firm's work ; (2) a similar proportion based on the time charged ; and (3) a proportion calculated in the same way upon the basis of wages paid. The object is that each department or work should be called upon to bear its fair share of the general expenses of the upkeep of the establishment, and that method is adopted which is best calculated to bring about this result.

# ELECTROPLATING

Preparation of Solutions. Preparation of Work. Silver-plating, Nickel-plating and Electrotyping. Current Strengths for Various Deposits

Group 10  
ELECTRICITY

24

Continued from page  
3282

By Professor SILVANUS P. THOMPSON

**Electrodeposition.** The general name of *electrodeposition* is given to every process for the deposition of metals from solution by the aid of the electric current. The term, therefore, includes silvering, gilding, coppering, nickelling, or depositing a layer of any metal upon the surface of any other piece of metal. It also includes the process of *electrotyping*—that is, the deposition by electricity of a type or shell of metal upon a prepared mould. Such general principles as govern the deposition of metals by the current will readily be comprehended by those who have mastered the previous article on Electrolysis [page 3258]. It will suffice to recapitulate here the main points that enter into the theory of the subject.

**Metallic Solutions.** The first point is that the metal to be deposited must be brought into a state of solution. For instance, if silver is to be deposited, a solution of silver must be prepared. If silver be boiled in nitric acid it dissolves, giving off fumes, and the silver remains in solution as nitrate of silver. Or dry crystals of nitrate of silver (a whitish solid) can be bought from the chemist, and dissolved in pure water. But the nitrate of silver, though silver can be deposited from it, is not a very suitable salt, as the layer of metal is apt to be crystalline, and experience shows that a smoother deposit is obtained from a solution of cyanide of silver than from a solution of nitrate of silver. To procure the cyanide solution, cyanide of potassium is added to the nitrate solution. This throws down the silver as a dirty precipitate, which is collected and re-dissolved in an excess of cyanide of potassium, forming a yellow liquid. (Cyanide of potassium is excessively poisonous, and therefore precautionary measures must be adopted.)

Electroplaters call the liquid so prepared, containing in solution the required metal, *the bath*, meaning the liquid in which the article to be plated is to be immersed. The articles to be plated they term *the work*.

In the article on Electrolysis it was shown how the electric current in passing through the liquid decomposes it, and carries the metallic constituent to the *kathode*. Hence, any object that is to receive the metal deposit over it must be arranged as the kathode of the depositing tank. In other words, it must be connected by a return wire to the negative pole of the dynamo or battery. If an insoluble anode were used, such as a plate of carbon, the liquor in the tank would become steadily impoverished of the metal in solution, and would become acid. To avoid this there is usually employed a soluble anode of the same metal that is to be deposited; for then, if all goes right, as much metal is dis-

solved off from the anode as is deposited at the kathode, and the liquid preserves its proper strength.

**Preparation of Work.** From what has been said it is evident that any surface which is to receive an electrolytic deposit must itself be a conducting surface, and, if not of metal, must be made conductive by being metallised before being put into the bath. Of this process more will be said below. But in the case of the plating of a thin layer of metal on another, as nickel on iron or silver or German-silver, it is not enough simply that the surface to receive the deposit should be of metal; it must be scrupulously clean, and the necessary processes for preparing the work are various and elaborate. Good deposits cannot be obtained unless this preliminary preparation is thoroughly carried out. In the electroplaters' workshop great use is made of *scratch-brushes*—which are brushes made of stiff brass bristles, and with which the surface of the work is scrubbed. Some scratch-brushes are worked by hand. More usually they are made to be attached to a rapidly-revolving spindle, like a lathe, and are driven at a high speed, while the object to be scrubbed is held against them. These scratch-brush removes any film of oxide and covers the surface over with minute scratches, giving the appearance of a dull polish. Some kinds of work are prepared by rubbing them bright with powdered pumice-stone on a wet rag. Some are cleaned by pickling them in acid. Old lacquer on the surface of brass can be removed by dipping into a boiling solution of caustic soda. Soda will also remove grease and dirt. But soda must not remain on the surface, and must be washed off in running water. Only experience can teach what is the best procedure for each kind of work. After pickling or scratch-brushing and a cleaning in soda, any work that is going to be treated in an acid bath should be washed off in very dilute nitric acid, and any work that is going to be treated in an alkaline or cyanide bath should be washed off in a very dilute solution of cyanide of potassium. After the last washing the object should neither be allowed to dry, nor to be fingered, but should be kept in the washing liquor or in running water until the moment when it is placed in the depositing tank. Care must be taken that it is properly connected metallically (by wires twisted about it, or even soldered to it) to the metal hook or wire by which it is suspended in the bath, and as this attachment involves fingering it should be made before the final washings.

**Silver-plating.** To make a gallon of the solution,  $3\frac{1}{2}$  oz. of nitrate of silver and 4 oz.

of cyanide of potassium (of 98 per cent. purity) are needed. When objects of copper, brass, or German-silver are to be plated, they should be polished, then hung for a few minutes in a hot solution of potash (1 lb. of American potash to the gallon), swilled with hot water, dipped for a few seconds into a weak cyanide solution, then scrubbed with wet Sheffield lime; next rinsed in water, then *quickly* by being plunged into a dilute solution of cyanide of mercury; again scoured with Sheffield lime, moistened with cyanide, then rinsed in hot water, and at once removed to the plating vat, through which the current should be already passing. The anode is a thin sheet of silver. All this sounds very elaborate, but it must be realised that electro-deposition is *an art* rather than a science, and that success is attainable only by long experience or by following carefully the skill of experience. For plating silver on soft metals, such as pewter or Britannia metal, even greater precautions are necessary, and the work must first either receive a thin deposit of brass in a brassing solution, or else it must be plated while hot with a thin flashing of silver in a dilute hot silver-bath with a strong current, after which it is removed to the ordinary silver bath to complete the plating.

**Brass-plating.** To make a gallon of brassing solution there are required 4 oz. of sulphate of copper, 4 oz. of sulphate of zinc, 8 oz. of carbonate of potash, 8 oz. of carbonate of ammonia, and about 8 oz. of cyanide of potassium (purity, 98 per cent.). The sulphates are dissolved in a flask in hot water. To this are added a few drops at a time of a solution of the carbonate of potash to precipitate the mixed hydrated metals. The precipitate is washed, and then a solution of carbonate of ammonia is added in sufficient quantity to redissolve the precipitate, forming a dark blue liquid. To this a solution of the cyanide of potassium is added, little by little, with stirring until the colour disappears. Then excess of cyanide is added, and the whole is boiled. An anode of brass is used. Great care must be exercised in regulating the strength of the current. If the current be too strong in proportion to the number of square inches of surface of the work, the deposit will be black or grey. If it be too weak, the brass deposited will be too red, like copper.

**Nickel-plating.** To make a gallon of nickelling solution, dissolve in hot water 12 oz. of the green crystals of the double sulphate of nickel and ammonia, filter, and add water to make up the gallon. As anode, use a sheet of pure nickel; do *not* use a carbon anode, as was formerly the fashion. The greatest care is necessary in the previous polishing and cleansing of the work, otherwise the nickel film may strip off, or show streaks. Also, the bath must not be allowed to become acid, otherwise the deposit will become spotty. Litmus paper should be used from time to time to test for acidity. Acidity is inevitable if carbon anodes be used. It can be corrected by adding a little solution of carbonate of ammonia. It is important to begin

with a strong current, to ensure that a deposit is flashed over the surface, after which the strength of the current should be reduced.

**Electrotyping.** This name is given to the deposition of copper upon a prepared mould. The Continental name is *galvanotype*, or *galvanoplastic*. [For the special applications of electrotyping in the printing trade, see the course on PRINTING.] The present article deals only with electrotyping as applied to the production of copies of medals, busts, statues, plaques, and the like. The first thing to be done is to make a mould of the object. The mould must then be *metallised* over its surface. Lastly, the copper is deposited on the metallised mould in the bath.

**Moulds for Electrotypes.** For nearly flat objects, such as coins and plaques, moulds can be made in gutta-percha, wax, or sealing-wax. For solid objects like busts and statues, special piece moulds must be made by a skilled moulder. For undercut objects in high relief, elastic moulds of gelatine may be made. We may describe gutta-percha moulding. The composition consists of one-third of tallow or fat, with two-thirds of gutta-percha. The fat is first melted, and the gutta-percha in small pieces is slowly added and stirred in, the utmost care being taken not to overheat the composition. The object to be moulded—for example, a metal medallion—is cleaned with naphtha, and laid down on a piece of board, with a surrounding rim of card or clay luted with plaster, to confine the gutta-percha. The object is then heated in an oven to dry the plaster. While still hot, some of the hot melted gutta-percha composition is brushed over it, and the composition is ladled over it to the required thickness and left to cool.

**Metallising the Mould.** Not until the mould has been cool for some hours should it be parted from the object. Its face must then be carefully brushed with a camel-hair pencil-brush charged with fine bronze-powder, which is gently rammed into the surface with the brush held perpendicular. All superfluous powder is removed, and the mould washed under the tap. It is then treated with a slightly acid solution of nitrate of silver, which turns the bronze grey. Then copper suspending wires are stuck into the edge of the mould in contact with the metallised surface, when it is ready to be hung in the coppering solution in the bath.

**Proper Strength of Current.** The following are the suitable densities of current:

| Process.                         | Amperes per 100 sq. in. |
|----------------------------------|-------------------------|
| <b>COPPER-TYPING.</b>            |                         |
| Best tough deposit .. ..         | 1½ to 4                 |
| Good and tough .. ..             | 4 to 10                 |
| Good solid deposit .. ..         | 10 to 25                |
| Solid deposit, sandy at edges .. | 25 to 40                |
| <b>SILVERING</b> .. ..           | 1 to 3                  |
| <b>GILDING</b> .. ..             | ½ to 1                  |
| <b>BRASSING</b> .. ..            | 3 to 3½                 |
| <b>NICKELLING</b> .. ..          |                         |
| At first, for few minutes ..     | 9 to 10                 |

TECHNICAL DRAWING  
continued from  
page 2269.

By JOSEPH W. HORNER

**Pulleys.** Pulleys are made either of cast iron, mild steel, or wood. Cast-iron pulleys may have straight arms, as 68, single curved arms, as 69, or double curved arms, as 70; sectional views are given in 71 and 72. The object in making the arms curved is to ensure a safe casting, since a straight arm does not yield so readily to accommodate the unequal contraction of rim and boss when the casting cools. The usual section of pulley arm is oval, as 73,

and B is the width of the section, and a safe stress for cast-iron pulleys is 2,000 lb. per square inch. Pulleys are, to a large extent, standard articles, and are manufactured for stock, consequently they are made to cover a wide range of loads. The table given below shows the average proportions of arms and rims for pulleys varying from 6 in. to 60 in. diameter and from 3 in. to 20 in. wide; the section of the arm as given is measured at the boss, the dimensions at the rim

are two-thirds of those values; the number of arms may be four for pulleys up to, say, 24 in. diameter and six for pulleys above 24 in. Looking at the sections 72 and 73, single arms are used up to 12 in. wide and double arms up to 20 in. wide. The length of the boss may be one and a half to two and a half times the

68. STRAIGHT-ARM CAST-IRON PULLEY 69. SINGLE CURVED-ARM CAST-IRON PULLEY

and it tapers from the boss to the rim. The forces acting on the arms tend to break them off, as in the case of the railway axle. The bending moment is found by multiplying the driving force on the rim of the pulley by the radial length of the arm and dividing by the number of arms. The modulus of an oval section is  $-\frac{3 \cdot 1416}{32} \times BA^2$ , where A is the depth

diameter of the shaft, while the thickness may be .45 times the diameter of the shaft; the boss and the inside of the rim should taper slightly in order to facilitate moulding. The rim of a pulley is slightly rounded, as shown in 74, and as dimensioned in the table. A belt will run on a *flat faced* pulley, but is safer when running on a *convex surface*; flat-faced pulleys are used in cases where the belt is to be moved

## DRAWING

sideways from a fast pulley to a loose one, as in 75, which represents a common device used for starting and stopping countershafts in connection with machine tools, etc.

**Wrot-iron and Steel Pulleys.** A wrot-iron pulley is shown in 76, 77 and 78; it is built in halves, and consists of a cast-iron boss and wrot-iron or steel arms and rim. The boss may be cast with the arms

The rim is curved on the face, and is formed with the edges bent round so as to combine stiffness with lightness; in the example given [79], the rim is doubled on itself so as to give a specially strong rim for extra heavy duty. The boss and rim are in halves and are bolted together as

75. FAST AND LOOSE PULLEYS

placed in position in the mould, or alternatively the latter may be screwed and tapped into the boss; the outer ends of the arms have solid collars and are cold riveted into the rim; a joint plate is fitted where the half rims meet. Cast-iron pulleys are also made in halves in a similar manner, but flanges are cast under the rims instead of using joint plates. The number of arms in a wrot-iron pulley varies from six to twelve according to diameter and thickness of rim; double arms [78] are used with this class of pulley when a width of 9 in. is exceeded; the diameter of the arm varies from  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in. These pulleys are generally made with a flat rim, but can be machined to a convex surface.

A pressed-steel pulley is illustrated in 79; the arms and rim are cold pressed into shape from steel plates; the arms are dished in cross section in order to give side stiffness, and also at the end where they are attached to the boss in order to relieve the rivets from shearing forces. An interlocking plate is riveted between the arms, where they are attached to the rim; this plate enters the rim and so helps the two outer rivets.

76. WROT-IRON PULLEY

shown; the whole pulley is a strong yet elegant example of its kind, the patent rights of which are held by the Phillips Company, of Philadelphia, United States of America.

**Relative Speeds of Pulleys.** A belt may not only be regarded as an agent for the transmission of power but also as a means of giving a certain speed to a shaft. Taking the case of a belt drive where both pulleys have

77. SECTION OF SINGLE-ARM

78. SECTION OF DOUBLE-ARM

the same diameter as 80, it is evident that both shafts will revolve at the same speed if "slip" be neglected; but if it be desired to drive one shaft at twice the speed of the other then one of the pulleys must be twice the diameter of the other; the circumferential speed of both pulleys

79. PRESSED STEEL PULLEY 24 INCHES IN DIAMETER

# DRAWING

80 BELT DRIVE—EQUAL PULLEYS

81 BELT DRIVE—UNEQUAL PULLEYS

Fig. 81, together with the following calculations, illustrate the above rules:

$$\text{Diameter of driven pulley} = \frac{36 \times 150}{270} = 20 \text{ in}$$

$$\text{Speed of driven shaft} = \frac{36 \times 150}{20} = 270 \text{ r.p.m.}$$

$$\text{Diameter of driving pulley} = \frac{20 \times 270}{150} = 36 \text{ in}$$

The thickness of the belt affects the calculations to a slight extent, because the true belt speed should be measured on the centre line of the belt; when a belt bends round a pulley its inner surface is compressed and its outer surface is extended,

but the centre line remains unaltered and is, consequently, the theoretical driving line. The difference is not very appreciable with single belts and medium velocity ratios; but in speeding up from a slow running shaft to a high-speed fan or dynamo it may upset the calculation to the extent of 3 per cent or even 5 per cent.

To find the diameter of a driven pulley to give a certain speed to a shaft, the diameter and speed of the driving pulley being known

Rule: Multiply the diameter of the driving pulley by its speed in revolutions per minute, and divide the result by the required speed of the driven shaft in revolutions per minute

To find the speed of a driven shaft having the diameters of both pulleys given as well as the speed of the driver

Rule. Multiply the diameter of the driving pulley by its speed in revolutions per minute, and divide the result by the diameter of the driven pulley

To find the diameter of a driving pulley, the diameter of the driven pulley and the speeds of both being given

Rule: Multiply the diameter of the driven pulley by its speed in revolutions per minute, and divide the result by the speed of the driving shaft in revolutions per minute.

pressed and its outer surface is extended, but the centre line remains unaltered and is, consequently, the theoretical driving line. The difference is not very appreciable with single belts and medium velocity ratios; but in speeding up from a slow running shaft to a high-speed fan or dynamo it may upset the calculation to the extent of 3 per cent or even 5 per cent.

**Speed Cones.** When it is desired to drive a machine at various speeds from a shaft running at a constant speed it is usual to employ speed cones as illustrated in 82, they are arranged opposite each other, so that the smallest pulley of one set is abreast of the largest one of the other set, the added diameters of any two

82 SPEED CONES

pulleys abreast of each other is a constant—i.e.,  $A + C' = B + B' = C + A'$ ; the driving belt can then be readily slipped from one set to another, and the speed of the driven set altered accordingly. Assuming the shaft D to be the driver, and to be running at 150 revolutions per minute, then when the belt is on A and C' as shown [82], the speed

of shaft E is  $\frac{150 \times 6}{12} = 75$  r.p.m.; when the belt is on B and B' the speed of shaft E is  $\frac{150 \times 9}{9} = 150$  r.p.m.; when the belt is on C and

A' the speed of E is  $\frac{150 \times 12}{6} = 300$  r.p.m. The

section of the cones is shown dotted; there are no arms except when the large cone is of a considerable diameter, or when there are a great number of steps, a boss and arms are then arranged to support it as shown in 83.

**Open and Crossed Belts.** Open and crossed belts are used on planing machines, screw-cutting lathes, etc., for the purpose of reversing the motion of a shaft after a certain operation has terminated. A typical example occurs in 84, where A is the driving pulley, B, C, and D are driven pulleys, B and D being keyed on the shaft and C running loose; the "open" belt is marked E and the "crossed" belt is marked F. Suitable striking gear is arranged to move both belts sideways at the same moment; when the belts are in the position shown [84], the open belt is driving the pulley B in the direction of the arrow G, whilst the crossed belt is driving the loose pulley only; upon striking the belts the open one drives the loose pulley and the crossed one drives pulley D, but in a reverse direction.

**Rope Driving.** Cotton and hemp ropes are used for the transmission of power in a similar manner to belts, but usually for main drives only. The textile mills of Lancashire afford numerous examples of direct rope driving from main engine shafts to line shafts on the various floors, the flywheel itself doing duty as the driving pulley. Ropes are made by twisting three "strands" together in a right-hand direction; each strand is formed of "yarns" twisted together in a left-hand direction, the yarns themselves being spun from cotton or hemp fibres in a right-hand direction. The diameter of the finished rope varies from  $\frac{3}{4}$  in. to 2 in.; the sizes in most frequent use are  $1\frac{1}{2}$  in. to  $1\frac{3}{4}$  in. diameter. The ultimate or breaking strength of a rope ranges between 7,000 lb. and 11,000 lb. per square inch. The safe working load is, however, only taken at 140 lb.

per square inch, or, say,  $\frac{1}{10}$  of the average breaking load, and unless this large factor of safety be allowed the life of the rope is short. A main driving rope should last from five to eight years.

83. SECTION OF LARGE CONE PULLEYS

The stress of 140 lb. per square inch does not represent the actual stress upon the fibres of the rope, but only that on the driving side due to the power transmitted. In addition to this, the rope has to sustain forces due to the wedging of the rope in the grooves of the pulleys and also the stress due to centrifugal action. This latter stress increases as the square of the speed of the rope—that is, if the speed be doubled the tension on the rope due to centrifugal force is increased four times, and if trebled is increased nine times; a speed is soon reached beyond which it is not economical to go, because the strength of the rope would be wasted in overcoming this force instead of transmitting power. The highest economical

84. OPEN AND CROSSED BELT

speed lies between 4,000 ft. and 5,000 ft. per minute, and at this speed the effective load on the rope is about 200 lb. per square inch instead of the 140 lb. per square inch due to the driving tension of the power transmitted.

**Powers of Ropes.** At 4,800 ft. per minute the powers which various ropes can transmit are as follow:

|                        |                      |                         |                       |
|------------------------|----------------------|-------------------------|-----------------------|
| $\frac{3}{4}$ in. rope | 8 $\frac{1}{2}$ h.p. | $1\frac{1}{2}$ in. rope | 29 $\frac{1}{2}$ h.p. |
| $\frac{7}{8}$ " "      | 11 $\frac{3}{4}$ " " | 1 $\frac{1}{2}$ " "     | 34 $\frac{3}{4}$ " "  |
| 1 " "                  | 15 $\frac{1}{2}$ " " | 1 $\frac{3}{4}$ " "     | 40 $\frac{1}{2}$ " "  |
| $1\frac{1}{4}$ " "     | 19 $\frac{1}{2}$ " " | 1 $\frac{7}{8}$ " "     | 47 $\frac{1}{2}$ " "  |
| $1\frac{1}{2}$ " "     | 24 " "               | 2 " "                   | 61 $\frac{1}{2}$ " "  |

These figures represent the maximum powers to be obtained from ropes at any speed whatever; further increase of speed does not result in an increased horse-power transmitted, but on the contrary, it steadily declines until at 8,000 ft. per minute the rope can barely withstand the centrifugal forces alone. Below 4,800 ft. per minute the power transmitted of course decreases, but not in exact ratio of speed, because as the speed becomes less, so the centrifugal forces decrease; at half the above speed—

DRAWING

viz., 2,400 ft. per minute, the following powers can be transmitted :

|   |   |
|---|---|
| $\frac{3}{4}$ in. rope = 6 h.p.           | $1\frac{1}{4}$ in. rope = 20 h.p.         |
| $\frac{1}{2}$ " " = 8 " "                 | $1\frac{1}{2}$ " " = 24 " "               |
| $1$ " " = 10 $\frac{1}{2}$ " "            | $1\frac{3}{4}$ " " = 28 " "               |
| $1\frac{1}{4}$ " " = 13 $\frac{1}{2}$ " " | $1\frac{7}{8}$ " " = 32 $\frac{1}{2}$ " " |
| $1\frac{1}{2}$ " " = 16 $\frac{1}{2}$ " " | $2$ " " = 42 $\frac{1}{2}$ " "            |

Since the capacity of a single rope is limited to a comparatively small horse-power, it is necessary to use a number of ropes on one pulley in order to transmit the required power, which may amount to several thousand horse-power in some cases. Small engines have from 3 to 10 ropes, larger ones 10 to 30, whilst some engines have been fitted with wheels having 50 and even 60 ropes.

**Rope Wheels.** The wheels are usually of cast iron and have machined grooves in the rim as shown in 85, the proportions of which are given in the table. The diameter of a rope pulley should not be less than 30 times the diameter of the rope, otherwise the life of the rope is shortened by the constant bending on too small a diameter. Rope pulley arms are usually oval in section, and may be calculated in a similar manner as described for belt pulleys; these pulleys are, however, more carefully designed and manufactured on account of their weight and of the higher speeds at which they run. Main driving pulleys on an engine frequently attain the enormous weight of 70 or 80 tons apiece. They are built up of a number of separate castings,

bolted or cottared together. Such pulleys are made from 20 ft. to 34 ft. diameter; smaller ones down to 12 ft. diameter are made in halves, but the rims are frequently built up in segments; from 12 ft. to 8 ft. diameter they are simply made in halves, whilst 8 ft. pulleys are cast in one piece. The object in building up the larger sizes is to ensure a wheel free from initial stress due to contraction; the stresses arising from centrifugal action alone when such heavy masses are moving at a high speed are very considerable, and, in fact, it is not wise or safe to exceed 5,000 ft.

per minute with a cast-iron rim. Heavy wheel rims have been known to burst at 4,500 ft. per minute. As the design of rope-driving pulleys is closely allied to flywheel design, it is more fully discussed under that heading in a later lesson.

**Arrangements of Ropes.** There are two methods of arranging the ropes for a given drive.

The usual plan adopted in England and on the Continent is to use a separate rope for each groove in the pulley, the ropes being spliced to as nearly the same length as possible. In America a different arrangement is extensively employed: a single rope is wound continuously in a spiral round the pulleys and is made to pass over a weighted pulley, which gives a certain tension to the ropes; by such means it is ensured that each rope element is taking its share of the drive. A great disadvantage of this method is that if the rope breaks the whole drive is at a standstill, and in all probability the rope becomes so entangled that a serious loss of time occurs before it can be got clear and a new rope reeved on.

Wherever possible the driving side of the rope should occur underneath, then the sag of the slack or top side increases the arc of contact and so adds to the efficiency of the drive. The length of a rope drive—i.e., the distance from centre to centre of the pulleys—should be as great as possible—from 20 ft. up to 80 ft. or 100 ft.; it is best to arrange it horizontally, or at most at an angle of 45 degrees. The sag of a rope follows a curve termed a "catenary" which approximates a parabola, and this latter curve may be used when drawing out a rope drive to determine clearances. Single-rope drives are used occasionally for special machinery and for overhead travellers; the ropes are then small in diameter in order to keep the pulleys down to a convenient size.

RAILWAY CONSTRUCTION  
continued from page 3259

By R. W. WESTERN

A ROAD of rails, although a great advance upon any other kind of road, differs from it in no essential principle. In the most primitive forms of transport the load is carried by man or animals, and sometimes dragged along the ground. The North American Indians carried their property over the prairie upon poles to which horses were hitched at one end as to shafts, the ends of the poles being allowed to trail upon the ground. When a load is placed upon any form of skid and drawn along, three results ensue: (1) the resistance due to friction and vibration; (2) the destruction of the surface of the ground passed over; and (3) the wear of the skid itself both from friction and jolting. The introduction of so simple a mechanism as the wheel effects a great improvement. The greater part of the friction can be concentrated at the hub thereof, where particular care can be taken to maintain conditions that reduce it to a minimum; also, since the friction is less, the destruction and wear is less, both of the vehicle and of the ground over which it passes.

**A Prepared Track.** Any considerable load, nevertheless, will force the wheel into the ground, causing resistance to progression and destruction of the surface of the ground unless it is very hard; also the disadvantages of jolting are but little reduced. The next step is to establish a prepared surface of ground to receive the wheel. This involves the disadvantage of confining the movement to the prepared surface, but the out-weighing advantages consist in the great diminution of resistance due to jolting, together with diminished destruction and wear of the vehicle and surface traversed.

The Romans are alleged to have conquered the known world by the introduction of good roads. The road of rails was an advance of almost equal importance. Here the surface over which the wheels pass is so confined and narrow that the hardest metal can be utilised and perfect smoothness insured, thus reducing the resistance due to wear and vibration to the lowest point attained.

**Resistance and Traction.** A steady pull equal to the weight of 70 lb. will move a ten-ton truck along a level stretch of railway at about ten miles per hour. On a smooth pavement a pull five times as great would be necessary to move a wagon weighing ten tons. On an ordinary macadamised road twice as much or 700 lb. would be needed. Over grass, perhaps 3,000 lb. or a ton and a half would suffice, while in the absence of wheels the load would be almost immovable.

If the speed of railway trains were confined to ten miles per hour, a comparatively slimy con-

struction would be strong enough, but at the high speeds which actually prevail, the action of the locomotive passing over the line is like that of an immense hammer—a steam-hammer, in fact.

Were the rail that carries the train to be supported directly upon a hard rock foundation, that rail, whatever its material, would be hammered out of shape or broken.

**Principles of Construction.** The rail, therefore, though held in a cast-iron chair to keep it steady, is supported by a wooden sleeper with some "give" in it. The principle of this is easily illustrated. Place a nut upon a hard surface and strike hard enough to crack it. Place it now on a thick piece of indiarubber; the same blow will not suffice to break it. If railway sleepers were placed upon a hard surface, even they would soon be broken up. Sometimes in rough countries they are placed upon the earth, but then the earth soon gives way under the hammering of passing trains, and a further objection is that contact with earth accelerates the rotting and decay of sleepers. The proper plan is to seat the sleepers upon a layer of broken stone called *ballast* or *metal*. It was discovered by the old road-makers Telford and Macadam that stone broken into fragments readily fits itself into a pretty compact mass, and while the stones rock a little under a blow, and thus absorb some of its energy, the pressure is transmitted in rapidly widening circles to the substance beneath them.

**Purpose of Ballast.** In the same way, upon a railway good ballast receives the shock from the sleepers and protects the earth beneath by distributing the shocks over its whole surface, thus subjecting the comparatively frail earth to pressure of an intensity within its capacity to sustain without flinching. It is this flinching or movement which must at all costs be avoided; if any material of construction, whether it be earth or ballast, will not remain where it is first placed, the integrity of the structure is at an end.

Complete immobility is, of course, unattainable. The aim of the engineer is to make any movement as gradual and uniform as possible; the effect of it will then be rather to strengthen and solidify the road as time goes on, provided that the packing and renewals of ballast are properly kept up.

**Drainage of the Road-bed.** The chief agency in causing undue and uneven movement in the road-bed is, again, water. Every precaution must be taken to keep the ballast and the earth beneath as dry as possible. For this reason a good slope is given to the latter [see 31 and 33, pages 3257 and 3258] so that any water

entering the ballast may quickly drain away. In addition to this, the surface of the ballast over the sleepers is sometimes smoothed over with a fine material, so that the greater part of a heavy rainfall is shed off from the surface at once, and has no time to enter the ballast.

**Description of Ballast.** The best material for ballast is a hard stone broken into irregular fragments of a size sufficient to pass through a ring two inches in diameter. This however, is often too expensive to use, and the

pounded into the earth, at the same time unduly depressing the centre part of the line, so that a long trough, in which water accumulates, is formed. This water soaks in and softens the middle of the earthwork until the bank may become little better than a raised reservoir of mud, liable to burst at any moment. It is therefore best to allow time for an embankment to become consolidated before laying down ballast, and, in any case, it is necessary to ensure proper drainage.

37 SECTION OF TRUCK, SHOWING TWO VARIETIES OF SLEEPERS

next best material is clean, coarse gravel. In any case, at least a foot must be interposed between the bottom of the sleepers and the ground or formation level in order effectually to distribute the pressures imposed, and two feet is commonly allowed between formation level and the top of the rails. In stations and yards where men and sometimes horses must walk over the line a great deal, a covering of cinders is placed over the sleepers almost up to the rail level, but in other parts the sleepers are often left uncovered.

**When to Lay Ballast.** It is usually undesirable to lay ballast down upon an embankment until some time—perhaps a year—after it has been completed. The rails and sleepers may, during this interval, be laid direct upon the earth. Of course, fast traffic cannot be put over the line while it is in this state, but the advantages of the method usually outweigh this drawback. The ballast is most economically laid by bringing it up in trucks by the engine and dropping it between and beside the rails. The sleepers are then lifted and propped up, and the ballast packed beneath them. If this be done too soon, while the earth of the embankment is soft, the soil quickly works up into the ballast, or, rather, the ballast is

**Permanent Way.** Typical sections of the permanent way of a railway are given in 31 and 33 [pages 3257 and 3258]. In these the ballast is shown carried out to the edge of the slope, which is very flat. The ballast is, however, generally stopped short of this, leaving a margin of about 18 in., called the *berm* or *cess*.

Sleepers in this country are usually of pine, 9 ft long, 10 in broad, and 5 in deep. The edges should be squared, because if they are rounded off there is danger that they have been cut from a tree not sufficiently large to allow of the section being squared, and this is usually objected to, since the wood near the bark of the tree is unduly encroached upon, and the nearer the wood is to the bark of the tree the softer it is, and the more liable to decay.

Chairs to carry the rails are almost universal throughout England. They may weigh  $\frac{1}{2}$  cwt each, and should, in that case, present a bearing area to the sleeper of 95 sq. in. and a bearing area to the rail of 10 sq. in. Two varieties of chairs are shown in 37. The chairs are fastened to the sleepers by nails, two of which are often of wood. A sketch of these is shown in 38. Usually neither are made with any taper. The keys by which the rails are wedged into the chairs may be made of some hard wood, or

38 NAILS FOR FIXING CHAIRS TO SLEEPERS

preferably of oak, and are commonly subject to pressure before being supplied for use. For a 56 lb. chair their dimensions would be 7 in. by 3½ in. deep by 2 in. thick, the taper being 1 in 16.

**The Position of the Keys.** The keys are commonly placed upon the outside of the rail, an arrangement by which a more elastic road is secured, though at the expense of several disadvantages. First of all, there is greater risk of the keys becoming loose, and, although this may be prevented by inserting keys of compressed wood in a very dry condition, this introduces stresses of considerable magnitude tending to rupture the chair, and chairs of defective casting frequently fail from this cause. Secondly, in the event of two or three consecutive keys coming out, the gauge of the line is affected in a more dangerous way than if the keys had been placed inside the rail. Thirdly, when inspecting a line of way a single inspector must walk twice over the ground, up one side and down the other instead of once down the centre, which would be sufficient if the keys had been placed between the rails.

**Rails.** The rails in such a line as we are considering would have a sectional area of about 8½ sq. in., and weigh 86 lb. per yd. They are usually rolled in lengths of 30 ft., though the present tendency is to make them longer in order to reduce the number of joints; but when heavy rails are made in great lengths it requires a large gang of men to handle them. In addition to rails of the normal length, it is necessary to provide a number 3 in. or 4 in. shorter for the inner edge of the curves. The object of this is to ensure that the joint on one rail shall come even with the joint of the other rail. The platelayers therefore insert one of these shorter rails whenever a curve is reached, and

39. RELAYING GANG PLACING A RAIL LENGTH IN THE CHAIRS

it is well to remember that approximately 1 in. of difference in the length of the rails of the two sides is required for each degree of curvature.

#### Laying the Rails.

The method of laying rails is as follows: First of all the sleepers are brought in trucks or waggons, and laid down approximately according to eye, 11 to every 30 ft., or as many as may be required for the spacing contemplated. It is better to make a mistake by having too many rather than too few, since the sleeper is not always at hand when required. The sleepers having been thus arranged, the chairs are fixed in the proper places upon them, first to those sleepers which are at the extremities

40. GAUGING HORIZONTAL ALIGNMENT OF TRACK

of the rails. The keys are then driven into the chairs of these sleepers, fixing them to the rails at the proper distance from their extremities.

The ends of the rails are then brought opposite each other, and the fish-plates are loosely bolted on to ensure the correct longitudinal position of the rail. Small pieces of steel are also placed between the ends of the rails to ensure that they are fixed at the correct distance apart to allow for expansion. The rails being now attached to sleepers at each extremity, the intermediate sleepers are shifted about until they are as nearly as possible in the positions they are ultimately to occupy. Fig. 39 illustrates a gang of men placing a rail length on the chairs.

The chairs are then slipped into position between the sleepers and the rails, and fastened upon the sleeper. This is done by two men; the first precedes with an auger, boring the holes, the second of which follows to drive in the trenails. It will be seen that by this manner of laying the rails the correct position of the chairs upon the intermediate sleeper depends upon the straightness of the rails, and as the rails are not always perfectly straight, it

41. INSPECTOR GAUGING THE TRACK

frequently occurs that the chairs are better fastened upon the sleepers before the latter are placed into position. If this be done, it is impossible to get a crooked or bent rail into position at all unless the rail laid parallel to it happen to be bent in exactly the same way. After the permanent way has been laid down in the manner described, the bolts tightened up and the keys driven home, a gang of 10 or 12 men go along the line to remove the slight lateral unevenness unavoidable at the first laying. The men are provided with crowbars [40], and when it is required to shift the lines they stand with their backs to the direction in which the movement is to be made, half the gang on each rail, and, putting the crowbar between their legs, they make a fulcrum of the ground beneath the rail, and so, leaning back together, displace it in the required direction. The ganger or head of the gang walks about 100 yd. behind them in order that he may by looking along the rails be able to tell them readily at what place to stop, as well as the direction and the amount of displacement required. Fig. 41 illustrates an inspector gauging the track.

**Essential Features of the Permanent Way.** It will be seen that the essential features of the permanent way are the rails, the fastenings of the rails to each other, the sleepers, the fastening of the rails to the sleepers, and the ballast. These are, of course, repeated mile after mile over the whole extent of the railway. The result of so much multiplication is to magnify enormously the importance of any modification in the design or relation of the parts, and however slight this may seem it requires the closest attention.

The type of permanent way already described is the one that is commonly used in Great Britain, and it has been found by experience to answer best under the conditions which obtain here. In other parts of the world different arrangements and designs have found favour.

**Other Types.** In India, where timber of all kinds is subject to the attack of white ants and other pests, cast-iron pot or plate and steel cross sleepers have been used with success. In North America the use of chairs is almost unknown. The rails are of the Vignoles section already described, and are fastened to the sleeper by spikes or nails, as explained when treating of the temporary way, though, of course, the work is much more carefully executed.

**Weakness of Vignoles Type.** A road so constructed is most likely to fail by the rails spreading, and thus allowing the wheels to run off the rails, especially at curves, where the centrifugal tendency of the rolling stock causes a heavy lateral pressure on the outside rail. This takes place, not because there is any tendency for the rail to slip sideways on the sleeper—frictional force alone is enough to withstand this—but because the rail tends to turn over about the

edge of its outer flange and crush the wood beneath it, as well as to draw the dog or spike on the inside. This tendency is commonly met by placing between the rail and the sleeper a bearing plate having holes through which the dogs or spikes are driven. An illustration of this is shown in 42.

**General Considerations of Design.** The several component parts of the permanent way are dependent one upon the other. To carry locomotives of a given weight at a prescribed speed, no one can be reduced below the standard formed by experience to be sufficient without increasing another. Thus, if the weight of the rails be reduced, the size of the sleepers and their number must be increased. And both the rails and the sleepers need to be of greater weight per mile of road if for any reason the quantity and quality of the ballast be inferior.

**Choice of Ballast.** In deciding upon the ballast to be used for a new line, the main consideration is generally the cost of obtaining the various kinds from which choice can be made.

Part of the cost of obtaining the ballast will be the expense entailed in bringing it to the spot where it is to be laid down, and this is often an item sufficiently important to cause different types of ballast to be chosen for different parts of the railway. In building a single line of way, the least quantity of ballast that can be employed without involving greater disadvantages than can be compensated for by the saving to be effected by using less amounts to 1,760 cubic yards per mile, which is a cubic yard for each yard of line.

In the absence of hard, durable stone, or satisfactory gravel, slag from the blast furnace in angular pieces is a very suitable material.

In places where every kind of hard substance is difficult to obtain, it is often sought to manufacture such a substance by burning a locally obtained clay. In every case in which an artificial material of this kind is adopted it is necessary to make sure that the burnt substance is both hard and likely to be durable. And it must be remembered that many rocks to be met with in Nature, though hard enough and tough enough to require the use of explosives to obtain them, will nevertheless prove most unsatisfactory in use. They may soften as the result of exposure to wet; they may scale away and split up under the influence of frost and change of temperature; or they may, in service, produce an undue amount of dust, the effect of which is most detrimental to the rolling stock. Hard limestones and sandstones, and, of course, granite and cognate material, is always to be relied upon. The railway built under conditions in which a plentiful supply of such material is available is a railway built under conditions favourable for economy in maintenance.

**Arrangement of Ballast.** Many engineers prefer to found the ballasting of a line

42 BEARING PLATE FOR SLEEPERS

on a layer of large stones, and so provide a solid foundation upon which to place the smaller material upon which the sleepers rest. Such stones, when laid together or *packed* by hand, form a structure known as *stone-pitching*. This device is, of course, expensive, and for this reason suitable only for exceptional situations where, from either the presence of an unusual amount of water or extraordinary traffic conditions, special measures are demanded. Experience shows that, unless the *packing*—i.e., adjusting the ballast beneath the sleepers—of the sleepers is accompanied by ample renewals of ballast these large foundation stones are apt to leave their places, and in subsequent operations of *packing* to be found near the surface, if not upon it, and interfering with this operation, as on account of their size they can be fitted beneath the sleepers with difficulty. This disadvantage is accentuated if the packed course be laid upon an embankment which is not sufficiently settled and solidified. As well as the ballast beneath the sleeper, it is usual in this country and in many other parts of the world to cover the sleepers with a finer material, reaching to the lower surface of the rails and extending some inches beyond the ends of the sleepers at the sides of the line of way. This is commonly referred to as *boxing-in* ballast; it adds to the weight of the permanent way, and is considered to preserve the sleepers. Doubts have been cast upon its utility, and it has been shown that the boxing-in ballast makes no increase in the resistance of the permanent way to lateral displacement. The merit of this covering-in material as a means of shedding off heavy rain has already been referred to. It may be added that in practice the finer top ballast is very likely from want of care to become mixed up with the layer ballast below it, thus reducing the efficiency of both.

### Spacing of Sleepers.

**Spacing of Sleepers.** The distance apart of the sleepers cannot well be less than 3 ft. from centre to centre, or there will be a difficulty in packing the ballast beneath them to keep a level line. The Americans do space their sleepers more closely but the latter are rather narrower, thus allowing more room for the packing tool to be used between them, and they are also shorter. In the United States, in fact, timber has been relatively cheaper than metal, and it is to such variations

### 43. HALF PLAN OF A SATISFACTORY METHOD OF SPACING SLEEPERS AT A DOUBLE CROSSING

in conditions that an engineer must look in order to decide what divergencies from the standard his design of permanent way should show.

The spacing of sleepers at the places where two lines of railway cross one another, or where a line of railway bifurcates, is always reduced. At such places the course pursued by a train is interrupted. When two lines cross, there is the inevitable jolt at the spot where the flanges of the wheels pass through the gap in the other lines made for that purpose. When bifurcation takes place, an angular lateral deviation of the course of the train is necessarily brought about, creating extra pressures that must be met with extra material. A satisfactory spacing for sleepers at a double crossing is shown in the half plan seen in 43.

**Wear of Sleepers.** A sleeper has to be removed from the line ultimately, either because, from the pressure and vibration of passing trains, the fibres of the wood have become separated and broken, or because, from exposure to weather, insects, and other influences, it has decayed. One cause is just as conclusive as the other, consequently there is no object in taking measures for protecting a sleeper from decay for a period longer than it takes to wear it out.

There are several methods of preserving timber, and of these creosoting is the most common. If the wood of which the sleeper is composed includes any *sap wood* of the tree—as the wood near the bark is called—some preservative method is usually essential. If, on the other hand, only *hard*, or *heart wood*, or wood cut from the centre of the tree, is contained in it, or if the sleeper is to be placed in a situation where the speed and density of the traffic is very great, it is often found that preservative processes are a useless expense, as the sleeper is pounded to pieces by the heavy driving-wheels of the locomotive before the decay begins. The use of chairs between the rails and sleepers enables some economy in the section of the rail, and also increases the life of the sleeper by distributing the pressure upon it over a larger area. The life of sleepers is very variable—anything from 5 to 20 years, according to conditions and circumstances.

### Selection of Sleepers.

**Selection of Sleepers.**  
In this country the supply of sleepers is a special branch of the timber

trade. The wood is imported for the most part from parts of Northern Europe, being cut from the forests of fir which abound there. Ability to distinguish between spruce and fir at a glance is very desirable, as the former cannot be recommended for permanent structures out of doors, though on account of its freedom from large knots it is preferred for scaffold poles and such purposes.

Sleepers should be of uniform size, as this assists in securing a uniform support to the rail. They should have a fairly clean surface, since a woolly or ragged surface sometimes left by the saw offers a readier harbour to the organisms of decay. They should, of course, be free from ring shakes, star shakes, and every other form of shake. The spiral grain to be found in many trees commonly converted into sleepers should also be avoided.

**Points for Guidance.** The twisted fibres frequently cause warping, which interferes with the proper seating of the sleeper upon the ballast beneath. Large knots so frequently found in fir are undesirable. They constitute, in any case, weak places where they occur, and when at or close to the part of the sleeper in which the spikes must be driven they afford reason enough for rejecting the sleeper for any but temporary purposes. The colour of the knots is in fir an indication of the quality of the wood.

Bright knots are signs of robust growth and plenty of resin, which discourages organic life. Dull, dark knots have a contrary significance. Sleepers

which have not undergone a preservative process, such as vulcanising, creosoting, burnettising, kyanising, etc., should be void of all sap wood, or their durability will be very short. Sleepers which have been so treated may contain sap wood, but it is important to make sure that the whole of the sap wood has been reached by the process which is intended to preserve it.

**Varieties of Sleepers.** Specifications sometimes require that but one sleeper shall be cut from a single length of tree trunk, thus forming what in the United States of America is called a *pole-tie*. The centre of the tree is then the centre of the tie or sleeper. Such sleepers are considered to be particularly long-lived.

A *slab-tie* is one of two cut from the same length of tree trunk, the centre of the tree coming at the centre of one of the faces of the sleeper, and this face should be placed upon the ballast when the sleeper is in position on the line. The expression *quarter-tie* in the light of the above explains itself. None of these distinctions are of great importance when a process preservative of the timber has been adopted.

In the Colonies, and for light railways in this country, it is not uncommon to use half-round sleepers. This is simply a trunk cut in halves

longitudinally, and the bark removed. It is always important to see to the latter even in the roughest construction, since fermentation is apt to be set up within the bark, which quickly leads to the destruction of the wood.

**Sleeper Dimensions.** Although the standard dimensions for sleepers in the United Kingdom are 9 ft. by 10 in. by 5 in., these sizes are not always followed in other countries, even when the line is of our standard gauge—4 ft. 8½ in. In America from 8 ft. to 8 ft. 6 in. is more usual for the length, 8 in. to 9 in. for width, and 6 in. to 7 in. for depth. American sleepers are therefore shorter, narrower, and deeper than ours. The reduction of length has already been referred to. It is partly explained by the fact that the earthwork on American railways is often skimped, and there is no room for a longer tie. The reduction of width enables the sleepers to be placed closer from centre to centre than would otherwise be the case, and in the absence of a chair avoids too long a bearing surface for the rail. It will easily be understood that the tendency of the rail to bend under the weight of the train passing over it causes it to bear with uneven pressure upon the sleeper. The pressure is greatest first on one edge of the sleeper and then on the other.

**Supporting the Rail.** The broader the sleeper, or the longer the piece of the rail that bears upon the sleeper, the more accented is this effect, with the result that the sleeper rocks on the ballast and works itself loose,

44. LONGITUDINAL SLEEPER AND RAIL

while the rail works on the sleeper and cuts across its fibres until the spikes get loose. The introduction of a bearing plate, as explained and illustrated [42], obviates the latter, but not the former tendency. A complete remedy is only to be found in the chair, which not only permits the use of a broad sleeper, but, by distributing the pressure of the rail over the whole surface of the base of the chair, enables the use of a sleeper not so stiff as is found necessary in America, where the sleepers are shorter and more numerous. The explanation of this divergence of practice must be sought in the relative cost of materials. A little reflection will show that by means of the same weight of timber a larger bearing surface of the sleepers upon the ballast would be effected in England in comparison with the usage in America. Thus, timber is economised at the expense of the cast iron used for the chairs.

**Treatment of Sleepers.** A usual length for sleepers is one and three-quarter times the width of gauge. When building a line of railway through land upon which timber suitable for sleepers is growing and available for the purpose, at economical prices, it is well to provide that they shall be hewed on two sides, that the two sides thus hewed shall be parallel, and that all bark shall be

removed and the ends sawn off square. The trees should be felled as far as possible in mid-winter; midsummer is the next best season. The sleepers should be piled up along the line 7 ft. or 8 ft. from the rails. The piles should rest on two pieces of waste wood or defective sleepers, and should consist of layers of sleepers placed alternately in directions at right angles with each other, allowing plenty of space for the circulation of air between. The sleepers should be so piled six months, if possible, before they are laid down.

**Life of Sleepers.** In deciding the quality of sleepers to be adopted upon a line, it is necessary to form some opinion regarding the probable life of the various kinds from which

that it remains a longer time before it must be renewed, thus obviating the necessity of so frequently disturbing the track, and in this way favouring smooth running of the trains and less wear and tear on the rolling stock and permanent way.

In Great Britain, where timber is dear and money relatively cheap, preservation of sleepers is almost universal. In Canada, where contrary conditions obtain, the reverse is the rule.

**Longitudinal Sleepers.** The subject of sleepers cannot be dismissed without referring to the system of longitudinal sleepers, which at one time had a great vogue, and is not yet entirely abandoned, particularly as the reason which led to their adoption and the reasons that

45 OLD READING STATION WITH LONGITUDINAL SLEEPERS

choice may be made. If a hard-wood sleeper is expected to last twice as long as another and is quoted at a price half as much again, it becomes a matter of calculation which is really the cheaper of the two, the calculation should not be evaded because the data upon which it must be based is usually somewhat vague in its character. The same applies to processes of preservative treatment. The life of an untreated soft-wood sleeper may be six or eight years, and that of the same sleeper properly preserved 12 or 14 years in similar situations; upon this an estimate of the relative economy of the two may be based, remembering that the longer-lived sleeper has this in its favour,

have since determined their abandonment are good examples of how changes in conditions affect railway design.

An illustration of the longitudinal sleeper and the form of rail associated with it is given in 44, and also in the reproduction of the photograph [45]. Large balks of timber are placed lengthways beneath the rails, giving continuous support. The sleepers are connected every 6 ft. or 8 ft. by transoms of wood, 4 in. by 6 in. These are notched into the sleepers and held by bolts, so that the gauge of the line may be maintained with certainty. Thin pieces of hard wood are laid with the grain crossways between the rail and the sleeper, to prevent the latter being cut into

Of course these large balks of timber, having to be cut from large trees, are relatively more expensive than the smaller wood that is used for cross sleepers, and drainage is more difficult, as water tends to run along the line of the sleepers. This involves better ballast and more of it. These considerations have been found to outweigh its manifold advantages, and have brought about its disuse, at all events for the time. Less cogent reasons are found in the cumbersomeness of the heavy timber, and the necessity of removing a whole rail when a sleeper had to be replaced in making repairs on the line. Reference to the satisfactory nature of the joint that is made possible by the use of longitudinal sleepers will be made in dealing with the subject of rail joints generally.

**Iron Sleepers.** An immense variety of iron sleepers have been devised. In some, the sleeper and rail have been combined in one longitudinal piece. In others wrought-iron rails have been joined to cast-iron posts. One of the most used forms is the steel sleeper shown in 46. The illustration explains itself. The arrangement is very useful for temporary work, as it is very light. There are cases also where the material for the permanent way has to be transported so far that the saving in freight of the lighter weight of steel sleepers has caused their adoption. Under ordinary circumstances, however, the relative prices of wood and steel being what they are, the use of steel for sleepers is not economical for the permanent way, unless, as in certain tropical countries, the white ant, or some analogous pest, is to be contended with. In such situations, it is also advantageous to use steel keys in the chairs, if the design of the permanent way adopted requires the use of keys. In fact, keys being in many situations more exposed to the attacks of animal and vegetable organisms than sleepers, it is often found economical to use steel keys with wooden sleepers.

**Function of Rails.** Rails give the name to the whole construction. All bridges, earthworks, and stations owe their existence to the rails, and the remainder of the permanent way is there for the purpose of supporting them. A railway consists essentially of nothing more than two strips of metal over which the wheels of the rolling stock may run smoothly and easily. Being constructed of steel, rails are able to withstand the blows and abrasion of all the passing traffic concentrated upon the narrow surface they present to it. The excessive pressures to which this surface is subjected, which

under fast traffic would quickly destroy any substance weaker than steel, are, by the arrangement and design, so spread out in transmission that they reach the earth below sufficiently diminished in intensity to be without appreciable effect upon it.

The earliest iron rails were simply strips of iron laid down upon wooden stringers with the object of reducing the amount of wear which obtained with rails made entirely of wood. It still remains a most important part of the function of a modern steel rail to provide metal for the wear occasioned by the traffic, but its function has long been very much extended. A rail must offer a sufficient resistance to bending under

a pressure from above to enable that pressure to be extended over several sleepers. Thus the blow delivered upon the rails by a jolt of an engine, which is received at the surface of the rails on the minute area over which the wheels are in contact with the metals, comes to be distributed over an area as broad as the permanent way itself and longer even than it is broad. This is so important that it must be insisted upon even at the risk of repetition. Just as a battleship is armoured against the blows of shot, the earth is armoured against the blows of the engine, otherwise it would be destroyed very quickly.

**Sections of Rail.** The two most common sections of rail, the *Bull-head rail* and the *Vignoles*, are shown with dimensions in 47 and 48. It will be easily understood that a very minute divergence in the form of the cross-section being continued throughout the mileage of a railway becomes a matter of great importance. Each square inch in the cross section accounts for 10 lb. per linear yard, so that in weight of material alone a small difference may greatly affect the cost. Consequently, it is important that the cross section of the rail should be designed so that every portion of it may contribute equally to the useful work of the whole. In order to allow for the quick wear, rails that will have to bear a very great deal of traffic, though not heavy fast traffic, will need a greater proportion of metal in the head of the rail

than would otherwise be provided. Rails that are to be laid down in thinly populated districts are apt to suffer more from rust than other causes. In such a case, and where the rails may be subject to the action of corrosive gases and other causes of decay, a greater comparative weight of metal in the web—the portion which joins the upper and lower flanges—will conduce to a longer life.

46. STEEL SLEEPER IN PLAN AND SECTION

47. BULL-HEAD RAIL

The Vignoles rail, for all round purposes, is usually rolled with 42 per cent. of the metal in the head; 21 per cent. of the metal in the web; and 37 per cent. of the metal in the foot or lower flange. With the bull-head rail practice is not so constant. The similarity of the upper and lower flanges in this case naturally suggests that the rail should be made reversible, so that when the metal provided for that purpose is worn off the head, the rail can be turned over to present another new surface to the abrading action of the wheels. This plan has often been tried but not continued. By the time the upper flange or head has been sufficiently worn to require the turning of the rail, the pounding of the traffic has, by hammering the lower flange upon the seat of the chair, so indented and fatigued the metal that it is no longer in a condition to serve as the head of the rail. It requires the passage of 15 to 25 million tons to wear away  $\frac{1}{16}$  in.—i.e., 1 lb. per yard (linear)—off a steel rail.

**Wear on Curves.** Rails laid down on curves of the line are subjected to special wear. The wheels of a railway's rolling stock are not arranged like those of road carriages. The wheel of a road vehicle turns round on its axle independently of the other wheel. The wheels of railway carriages and waggons are, on the contrary, fixed fast to the axles, and it is the latter that revolve in bearings provided for the purpose. This allows of a much stronger construction, but a result is that the two wheels fixed at each end of the axle are no longer independent, and must turn together or scrape along the rail.

In going round a curve it will easily be seen that one wheel (that on the outside rail of the curve) has further to go than the other, consequently one or both of them must slip. This slipping action has a very important influence in deciding the alignment of a railway. On a six-degree curve it may double the wear on the rails and affect the even flanges to an even greater degree, besides increasing the force required to draw the train. The effect of wear due to this action which obtains on curves is shown in 50. The effect of wear on straight portions of the line is shown in 49. Wear is most marked on the outside rail against the inner side of which the flange of the wheel is driven by what is known as centrifugal force. The grinding of the flanges of the wheels wears away the head of the rail at the side as well as at the top of the head. But the inside rail

is also ground in a less degree, because as the rectangle formed by the lowest points of the four wheels of a truck is going round a curve it has a tendency to stick, as any other square body that just passed easily between two parallel walls would tend to stick or jamb if the walls made a bend. Altogether the wear on the rails due to curvature amounts to about  $\frac{1}{4}$  lb. per degree of curvature, per linear yard per 10,000,000 tons passing over it in gross.

**Length of Rails.** Though the most usual length for rails is 30 ft., lengths of 45 ft. and even 60 ft. have been made and used, and warily advocated.

Obviously, the longer the rail, the fewer the joints; and joints are a source both of weakness and expense to a railway. Of course, increased length gives increased weight, and rails of a large cross-section are very heavy to handle. This, however, is not sufficient to balance the advantage of fewer joints. The chief drawback to very long rails lies in the difficulty of providing means for expansion due to change of temperature. Long rails are therefore of special value only in situations where the range of possible temperatures is moderate.

In laying down the permanent way the plate-layers place a small piece of metal, which is often

called a *skim*, between the ends of the two rails at each joint to ensure that they shall be laid at a distance apart suitable to allow for the changes of length brought about by variations of temperature. Where 30 ft. rails are being laid, the thickness allowed may be  $\frac{1}{8}$  in. for the coldest weather and  $\frac{1}{16}$  in. for the very hottest. About  $\frac{1}{4}$  in. is required for every 20° F. in the range of temperature.

When laid upon a curve the length of one rail must be increased or reduced a little, or, since the inner rail is the shorter of the two, the joints on this rail will gain upon the joints on the outer rail. If  $\theta$  be the angular divergence of the curve and  $r$  ft. the radius of the outer rail, the difference in length

will obviously amount to  $\theta r - \theta (r - 4.83)$  for a line of standard gauge. Thus the difference

for each degree becomes  $4.83 \times \frac{\pi}{90} = .084$  ft. or

1 in. nearly. Hence, it is common to provide a number of rails cut 4 in. shorter than the rest, i.e.,—29 ft. 8 in., and to allow three for every 12 degrees of curvature.

48. VIGNOLES RAIL.

49. WEAR OF RAIL ON A STRAIGHT TRACK

50. WEAR OF RAIL ON A CURVED TRACK

# FROM SCOTT TO STEVENSON

Being a Short Study of English Prose Fiction, chiefly of the Victorian Era.  
Bulwer-Lytton, Disraeli, Thackeray, Dickens, the Brontës, George Eliot, etc.

By J. A. HAMMERTON

**I**F we ever had any measure of doubt as to the importance of the novel in the literature of our country, we could have gone but a little way in the study of nineteenth century fiction ere we realised that one of the chief glories, if not, indeed, the chief glory, of English letters during that period was the novel. We have seen how the novel originated, how it was acclimatised in England, and how in the prose fiction of Scott it reached, so soon in its history, the very height of its possibilities. In the present study we shall follow its development from the time of Scott to the close of the last century, but confining our attention only to the novelists whose careers have been rounded off by death. Perhaps the most striking fact disclosed by this survey is the evolution of what was originally a form of amusement into an instrument of social, political, and religious propaganda. One often hears about "the novel with a purpose," as though it were a new thing; but long ago Dickens and Charles Reade proved that the novel was a powerful means—perhaps the most powerful—of awakening the conscience of the nation. Although the novel with a purpose has flourished and still flourishes with us, "The Jungle" being the latest example, on the whole there are signs towards the close of the period dealt with of a return to romance.

**Contemporaries and Disciples of Scott.** One of Scott's contemporaries and followers in fiction was JOHN GALT (b. 1779; d. 1839). Galt wrote a long series of Scottish tales, and was the real progenitor of the so-called "Kailyard School" of Scots fiction, which came so much to the front in the last decade of the century. The pathetic "Autobiography of Mansie Waugh," often attributed to him, was, however, the work of DAVID MACBETH MOIR (b. 1798; d. 1851). THOMAS HOPE (b. 1770; d. 1831) in his "Anastatius" showed what could yet be made out of the storied East. JAMES JUSTINIAN MORIER (b. 1780; d. 1849) also wrote several Oriental romances. In "The Adventures of Hajji Baba in Ispahan" his intimate knowledge of Persian life is displayed to advantage. The art of romance writing is also exemplified in "Salathiel," "Tales of the Great St. Bernard," and "Marston" of the REV. GEORGE CROLY (b. 1780; d. 1860). JOHN WILSON (b. 1785; d. 1854), the "Christopher North" of "Blackwood's Magazine," was, like Galt, a follower of Scott. His "Lights and Shadows of Scottish Life" and "The Trials of Margaret Lindsay," on which his reputation as a fiction writer may be said to rest, are, however, but little read to-day. THOMAS LOVE PEACOCK (b. 1785; d. 1866)

poured no little wit and knowledge of character into the seven novels which stand to his name—"Headlong Hall," "Melincourt," "Nightmare Abbey," "Maid Marian," "The Misfortunes of Elphin," "Crotchet Castle," and "Cryll Grange." These works remain, like those of Landor, caviare to the general reader, but must not be neglected by the student. Their whimsical humour is set off by the songs and lyrics scattered through them.

**The Early Lady Novelists.** FRANCES TROLLOPE (b. 1780; d. 1863), the mother of Anthony Trollope, was an industrious writer, of whose many novels "The Vicar of Wrexhill" and "The Widow Barnaby" are best remembered. Her books will always appeal to students of the manners and the temper of one of the most interesting periods of modern English history. SUSAN EDMONSTONE FERRIER (b. 1782; d. 1854) was a caustic but kindly-hearted delineator of old maids, pretty inanities, gauche doctors, and mock heroes. Like Maria Edgeworth and Fanny Burney, Miss Ferrier, in "Marriage," "The Inheritance," and "Destiny," laid bare the "humours" of her time. A gifted satirist of her sex, she found a wealth of material in the society amidst which she moved in Edinburgh. Some of her works are still occasionally reprinted, and the general reader as well as the student will find profit in them. The character not less than the literary gifts of SYDNEY LADY MORGAN (b. 1785; d. 1859) are well illustrated in her novel, "The Wild Irish Girl." MARY RUSSELL MITFORD (b. 1787; d. 1855) wrote "Our Village," a series of delightful sketches which enshrine the life of the little hamlet of Three Mile Cross, near Reading, with a fidelity borrowed from Crabbe, a smoothness that recalls Miss Austen's pictures of Steventon, and a pleasant humour that was all her own.

**The Romance of the Sea.** With WILLIAM NUGENT GLASCOCK (b. 1787; d. 1847) began the modern novel of the sea, which developed in the hands of MICHAEL SCOTT (b. 1789; d. 1835), author of "Tom Cringle's Log" and "The Cruise of the Midge," two of the best sea stories ever written, though discursive and lacking literary grace; JAMES HANNAY (b. 1827; d. 1873); EDWARD HOWARD (d. 1841), who wrote "Rattlin the Reefer"; and CAPTAIN FREDERICK CHAMIER (b. 1796; d. 1870), the author of "Ben Bracco"; and culminated in the extravagant but popular romances of CAPTAIN FREDERICK MARRYAT (b. 1792; d. 1848) and WILLIAM HENRY GILES KINGSTON (b. 1814; d. 1880). Marryat's "Peter Simple," "Jacob Faithful," and "Mr. Midshipman Easy" are, perhaps, the best and most popular of his

many works. Their author owed much to his study of Smollett, whose influence is also revealed in the novels of THEODORE EDWARD HOOK (b. 1788; d. 1841), the author of "Jack Brag." Hook's gift for satirical caricature was probably not without influence on Dickens.

#### Some "Half - forgotten" Novels.

RICHARD HARRIS BAHAM (b. 1788; d. 1845), author of the ever entertaining "Ingoldsby Legends," and friend and biographer of Hook, wrote one novel in his later years, "My Cousin Nicholas." MARGUERITE, "the most gorgeous" COUNTESS OF BLESSINGTON (b. 1789; d. 1849) was the butterfly of a day. Her numerous novels, together with the "Keepsakes" and "Books of Beauty" which she edited, are now forgotten. The veil of oblivion has also fallen over the historical novels of ANNA ELIZA BRAY (b. 1790; d. 1883) and the tales of ANNE MARSH CALDWELL (b. 1791; d. 1874). EDWARD JOHN TRELAWNEY (b. 1792; d. 1881), the friend of Shelley and Byron, will long be remembered through his delightful "Adventures of a Younger Son," a novel which is largely of an autobiographical character.

**The Romance of War.** With WILLIAM HAMILTON MAXWELL (b. 1792; d. 1850) we come into touch with a school of military novelists which also included GEORGE ROBERT GLEIG (b. 1796; d. 1888), CHARLES JAMES LEVER (b. 1806; d. 1872), author of "Charles O'Malley" and some three dozen other rollicking Irish stories, many of them extremely entertaining and extremely untrue to life, and JAMES GRANT (b. 1822; d. 1877), of whose fifty-odd works "The Romance of War" and "Adventures of an Aide-de-camp" are still worth reading. The "Traits and Stories of the Irish Peasantry" will represent WILLIAM CARLETON (b. 1794; d. 1869); and of the writings of SAMUEL LOVER (b. 1797; d. 1868), another Irish novelist, "He Would be a Gentleman" and "Handy Andy" are among the best. JOHN BANIM (b. 1800; d. 1842) and MICHAEL BANIM (b. 1796; d. 1874) collaborated in "The O'Hara Tales," a series of melodramatic stories illustrating Irish life, also reflected in the novels of Mr. S. CARTER HALL (b. 1800; d. 1881). MARY WOLLSTONECRAFT SHELLEY (b. 1797; d. 1851) wrote in "Frankenstein" a novel which, despite its horrible theme—the creation by a student of a semi-human monster—possesses sufficient of the elements of human interest to preserve it from oblivion. CATHERINE CROWE (b. 1800; d. 1876), authoress of "Susan Hopley," was another novelist with a leaning to the supernatural.

**A Word on Melodrama.** The historical novels of GEORGE PAYNE RAINSFORD JAMES (b. 1799; d. 1860) possess little interest to-day save that they illustrate how a man with sound knowledge but little imagination may imitate the example of such a genius as Scott without conveying a scintilla of the vivacity or charm of the model. Much the same may be said of the romances of WILLIAM HARRISON AINSWORTH (b. 1805; d. 1882), except that Ainsworth may be considered as the father of the novel which depends upon a succession of exciting incidents

for its popularity—that is to say, the melodramatic novel. Much of the fiction which is most popular to-day is sheer melodrama, and possesses no likeness to life. Merely to invent "situations" and bend the whole tale to fit these incidents is to produce a low, but always popular and often readable, form of fiction.

**George Borrow and Others.** Passing the "society" novels of THOMAS HENRY LISTER (b. 1800; d. 1842) and CATHERINE FRANCES GORE (b. 1799; d. 1861), the one novel ("Deerbrook") of HARRIET MARTINEAU (b. 1802; d. 1876), and the essays in fiction of DOUGLAS WILLIAM JERROLD (b. 1803; d. 1857) we find much that is worthy of careful study in the works of GEORGE HENRY BORROW (b. 1803; d. 1881), whose "Lavengro" and "The Romany Rye" did so much to inspire "the renaissance of wonder." They are splendid in the virile simplicity of their style and charm by reason of the intense interest which the reader immediately feels in the narrative, which is largely autobiographical.

**The Novels of Bulwer - Lytton.** EDWARD GEORGE EARLE LYTTON BULWER-LYTTON (b. 1805; d. 1873) was in a sense a parent of the penny novelette. With a versatility akin to genius he turned his hand to many kinds of literary work, and succeeded, for a time at least, in nearly all that he attempted. There were two exceptions—he failed as a poet and he made a sad hash of his private life by an ill-advised marriage. One of the most prominent and, during his lifetime, one of the most popular of the Victorian novelists, he played a part in fiction similar to that fulfilled by Byron in poetry. He posed as the man of the world in "Pelham," as the man of feeling in "Ernest Maltravers" (which Miss Barrett admired against Browning's severer judgment), and as the man of mystery in "Zanoni." The novel of horrors has in "A Strange Story" a supreme example; than "The Haunted and the Haunters," contributed to a magazine which had hailed Lytton as a charlatan, no better ghost story has been written. Lytton essayed the historical romance in "The Last Days of Pompeii," "The Last of the Barons," "Rienzi," and "Harold"; the criminal novel in "Paul Clifford" and "Eugene Aram"; and the novel of domestic life and ambition in "The Caxtons," "My Novel," and "What Will He Do With It?"

It is easy to condemn Lytton, as it was easy, once the trick of his style had been caught, to imitate or to satirise his work; but this work has a certain importance for the student of literature of the period in which Lytton wrote, and of the evolution of the English novel. For a time Lytton's success eclipsed the popularity of Scott; that Scott came to his own again, and that Lytton now occupies quite a minor place in English letters, are facts the reasons for which will soon be fairly obvious to any conscientious student.

ROBERT SMITH SURTEES (b. 1803; d. 1864)—"Jorrocks"—wrote a number of sporting sketches which are believed to have suggested to Dickens the plan of the "Pickwick Papers."

**Lord Beaconsfield as a Novelist.**

A writer who, with Ainsworth and Lytton, came under the lash of Thackeray's pungent satire, but who was a much greater man than either, was BENJAMIN DISRAELI (b. 1804; d. 1881). Disraeli's career and versatility afford a parallel to the life and activities of Lytton; but the author of "Vivien Grey," "The Young Duke," "Contarini Fleming," "Henrietta Temple," "Venetia," "Coningsby," "Sybil," "Tancred; or, the New Crusade," "Lothair," and "Endymion," won greater distinction as a statesman than as a novelist, and his works are valuable chiefly as so many keys to the secret of his extraordinary progress from obscurity to power and place. "Coningsby," "Sybil," "Tancred," "Lothair," and "Endymion" possess permanent interest for the student of politics.

**Mrs. Gaskell and Others.** Between Disraeli and the next great figure on our list come the names of JULIA PARDOE (b. 1806; d. 1862), whose sketches of Eastern life are of some value; SAMUEL WARREN (b. 1807; d. 1877), the author of "Passages from the Diary of a Late Physician" and "Ten Thousand a Year"; ANNE MANNING (b. 1807; d. 1879), who wrote a series of tales of sixteenth century life; PHILIP MEADOWS TAYLOR (b. 1808; d. 1876), the author of several capital tales of Indian life, including the "Confessions of a Thug"; and ELIZABETH CLEGHORN GASKELL (b. 1810; d. 1865). Mrs. Gaskell's "Mary Barton," a story of factory life, and "Cranford" form a link between the work of Jane Austen and that of Charlotte Brontë, whose biographer she was.

**The Two Aspects of Thackeray.**

WILLIAM MAKEPEACE THACKERAY (b. 1811; d. 1863) has to be considered, as Scott is considered, in two aspects—as a great novelist and as a great moral influence. No one who knows his Thackeray can ever misinterpret the meaning of the word "gentleman," or, with Thackeray in his mind, fail to distinguish the real from the sham in character or in sentiment. Thackeray has been lightly called a cynic. The word applied to him is wholly misused. No writer since Scott had so true or gentle a heart as Thackeray had, and his works are indeed, like Scott's, "a liberal education." At the same time there is a great deal of force in the contention that, whilst Thackeray saw, loved, felt, and makes us love the higher, brighter, purer side of life, he had a surer hand when depicting what was base and artificial. For explanation of this we must look to the political and social circumstances of the time in which he lived and wrote, and to his peculiar sensitiveness to all around him. Thackeray was no cynic, but he is the greatest of English satirists, a man who gibbeted snobbery for all time, having first of all dissected its anatomy and laid its organs bare.

**Thackeray's Philosophy and Realism.**

With Thackeray, philosophy worthy of the name first showed itself in English fiction; by the side of Thackeray's work, what Lytton passed off as philosophy is seen to be mere (even if unconscious) affectation. Of Thackeray's

novels, "Pendennis," "Esmond," and "The Newcomes" are unquestionably the masterpieces. They reflect life. As Professor Saintsbury says: "Every act, every scene, every person in these three books is real with a reality which has been idealised just up to, and not beyond, the necessities of literature. It does not matter what the acts, the scenes, the personages may be. Whether we are at the height of romantic passion with Esmond's devotion to Beatrice, and his transactions with the duke and the prince over diamonds and title-deeds; whether the note is that of the simplest human pathos, as in Colonel Newcome's deathbed scene; whether we are indulged with society at Baymouth and Oxbridge; whether we take part in Marlborough's campaigns or assist at the Back-kitchen—we are in the House of Life, a mansion not too frequently opened to us by the writers of prose fiction." Of the much-debated "Vanity Fair" it must suffice if we say that it admirably exemplifies Thackeray's creed, which, simply put, is that goodness, however it may be scorned, is its own sufficient great reward. One of the giants of English letters in the last century, it is, of course, unnecessary to say that the whole library of his works must attract the student and the general reader alike.

**Charles Dickens.** Before turning to the works of CHARLES DICKENS (b. 1812; d. 1870), the young student could not do better than read the "Life" of Dickens by Forster. Although often criticised, that is an excellent biography, ample in its information, intimate in its knowledge, and the reading of it is wonderfully stimulating. It is beyond all computation how many have been helped to smile through their tears and to take their courage in both hands under the influence of the inimitable, imperishable humour of Charles Dickens. Dickens saw the soul of goodness in things evil; his was the saving grace of humour; and his books, appealing to a far wider circle than the works of Thackeray, are among the best examples English literature has to show of the novel with a purpose. Where Thackeray inspires our admiration, Dickens compels our love. He has enshrined in his wonderful portrait gallery not only the short and simple annals of the poor of a period happily now no more, but he has shown us the possibilities of goodness and of happiness even in the most unlikely circumstances and characters. He has moulded and fashioned common clay till we see its relationship to that which goes to the making of the finest porcelain. Through him the rich have come to understand the poor, and the poor have arrived at a clearer realisation of themselves. What Dickens stood for in a social sense has been long since largely attained; and the pose that affects to find his writings coarse or obsolete is an unworthy affectation to be pitied, perhaps, more than condemned.

**Dickens's Merits and His Limitation.**

Dickens was "self-educated"; he had obvious limitations, but his absolute genius is even more pronounced than that of Thackeray, of whose pictures of high life Dickens's transcripts from

humble life may be said to form a necessary counterpart. Indirectly, Dickens may be taken as a warning by the young writer. When Dickens, as in "Oliver Twist," wrote of what he knew, he fashioned for himself a permanent niche in the temple of fame. When, as in "Nicholas Nickleby," he attempted to illustrate a phase of life with which he was unacquainted, he failed sadly. After reading the "Life" the student should read "David Copperfield," which is largely autobiographical. Of Dickens's novels it has to be said that they are chiefly tales of town life; that, in the main, their plots are indifferent, though he is not lacking in the element of drama; and that their success depends upon their character studies or "humours," as Jonson would have called them. As he wrote so largely of social conditions which have passed away, later generations may find their interest in his works less readily excited than was the case with our fathers; for the present generation is not quite so devoted to Dickens study as the last; but his novels are among the imperishable possessions of our national literature and command the attention of every student of English fiction.

#### From Reade to Kingsley.

CHARLES READE (b. 1811; d. 1884), who, like Dickens, "wrote with a purpose," but who, unlike Dickens, was a scholar of no mean attainments, attacked prison scandals in "It is Never Too Late to Mend," private lunatic asylums in "Hard Cash," and coffin ships in "Foul Play." He has left us a vivid picture of factory life in "Put Yourself in His Place," but his greatest book is indubitably "The Cloister and the Hearth," a mediæval romance based on the "Colloquies" of Erasmus. JOSEPH SHERIDAN LE FANU (b. 1814; d. 1873) was an Irish novelist with a strong bent towards the "uncanny." He wrote some sixteen books in all, of which "Uncle Silas" is perhaps the best. No one has excelled him in the writing of the

ghost story; not even R. L. Stevenson could "achieve the grue" with such weird success as Le Fanu. ANTHONY TROLLOPE (b. 1815; d. 1882) should be approached first of all in his "Autobiography." His innumerable novels, of which "Barchester Towers," "Framley Parsonage," and "Orley Farm" are the chief, contain some charming studies of women, and represent very faithfully English clerical life. They are invaluable to the student of the Victorian era, and will almost certainly enjoy in the future far greater popularity than they have had since Trollope passed away. CHARLOTTE BRONTË (b. 1816; d. 1855) struck

in "Jane Eyre," "Shirley," and "Villette" the first clear bell-note of modern English womanhood. Her work is part of her own pathetic life-story. EMILY JANE BRONTË (b. 1818; d. 1848) also displayed exceptional if morbid power in "Wuthering Heights"; and Charlotte's youngest sister, ANNE BRONTË (b. 1820; d. 1849), wrote two novels, "Agnes Grey" and "The Tenant of Wildfell Hall," which, while they gain in interest from their personal associations, vividly picture moorland scenery and the life of a governess. Before taking up the works of the three sisters the student should read Mrs. Gaskell's classic "Life" of Charlotte Brontë, and Mr. Clement Shorter's interesting little book on "Charlotte Brontë and Her Sisters."

#### SOME NOVELISTS OF THE VICTORIAN ERA

*Photograph of Trollope by London Stereoscopic Co.*

CHARLES KINGSLEY (b. 1819; d. 1875) was a follower of Frederick Denison Maurice and Thomas Carlyle, and a manly exponent of "muscular Christianity," or "Christian Socialism." His books possess the prime quality of stimulus: "Alton Locke" and "Yeast," in particular. "Westward Ho!" and "Hereward the Wake," fine historical romances, will always have a warm place in the hero-loving, adventure-seeking heart of youth. HENRY KINGSLEY (b. 1830; d. 1876), the brother of Charles, wrote several novels, chiefly of Colonial life. His masterpiece was "Ravenshoe," which

deserves to be remembered with the best work of the author of "Westward Ho!" and in the judgment of some critics is superior to any of Charles Kingsley's novels.

**A Great Woman Novelist.** GEORGE ELIOT (MARIAN EVANS) (b. 1819; d. 1880) is one of the greatest of English women novelists. As was the case with Jane Austen, and even more the case with Charlotte Brontë, George Eliot put herself and her actual experiences into what she wrote. Her books are, for the most part, real, sincere, earnest. Her genius flowered late; some of her writings have the effect of finished buildings from which all the scaffolding has not been taken down; but her contributions to the novel of manners, and particularly of the rural life of her native Warwickshire, are of lasting and living merit. With George Eliot the writing of fiction was the art of thinking aloud, the novel was a form of philosophy; but in the forefront of her philosophy, which, like Carlyle's, was devotion to duty, her characters stand out with lifelike fidelity. She was influenced more, perhaps, than any other English woman writer has been by her foreign, and especially German, studies. The "Scenes of Clerical Life," "Adam Bede," "The Mill on the Floss," and "Silas Marner" display her genius at its best. "Romola," a story of the Italian Renaissance, will always have its admirers. It betrays scholarship of no ordinary kind; but it was brilliant task work, and its author said afterwards that she was a young woman when she began the book and an old one when she finished it. "Daniel Deronda," another piece of task work, should be studied with Disraeli's "Tancred" by those interested in the mysteries of the Hebrew character.

**Other Notable Victorian Novelists.** Before passing to the one other great name that must detain us ere we take up a brief study of living novelists, mention must be made of the novels of Mrs. HENRY WOOD (b. 1814; d. 1887), authoress of "East Lynne"; Mrs. LYNN LINTON (b. 1822; d. 1898), who put much autobiographical material into her "Christopher Kirkland"; CHARLOTTE YONGE (b. 1823; d. 1901), authoress of "The Heir of Redclyffe"; DINAH MARIA MULOCK (Mrs. Craik), (b. 1826; d. 1887), who wrote "John Halifax, Gentleman"; MARGARET OLIPHANT (b. 1828; d. 1897), whose life-story is, perhaps, more interesting than any of her novels; ADA ELLEN BAYLY ("Edna Lyall") (d. 1903), authoress of "Donovan"; GEORGE JOHN WHYTE-MELVILLE (b. 1821; d. 1878), who wrote well of life in the "shires"; THOMAS HUGHES (b. 1822; d. 1896), author of "Tom Brown's Schooldays"; WILLIAM WILKIE COLLINS (b. 1824; d. 1889), author of "The Woman in White" and "The Moonstone," models of a long line of detective stories; GEORGE MACDONALD (b. 1824; d. 1905), whose

"Robert Falconer," "Alec Forbes," "David Elginbrod," and "Sir Gibbie" are full of the humour of Scottish life as seen by a devout Calvinist; JAMES PAYN (b. 1830; d. 1898), author of "Lost Sir Massingberd" and "By Proxy"; JOHN HENRY SHORTHROUSE (b. 1834; d. 1903), author of "John Inglesant"; WALTER BESANT (b. 1838; d. 1901), whose "All Sorts and Conditions of Men" prompted the People's Palace, and who collaborated with JAMES RICE (b. 1843; d. 1882) in "Ready-Money Mortiboy" and "The Golden Butterfly," the last-named of which contains many wholesome morals for the literary aspirant on the difference between doing work and thinking about it; WILLIAM BLACK (b. 1841; d. 1898), author of "A Daughter of Hoth"; RICHARD DODDRIDGE BLACKMORE (b. 1825; d. 1900), who wrote nothing better than "Lorna Doone," a romance of his native Devonshire; GEORGE GISSING (b. 1857; d. 1903), to whom culture was no protection against the pessimism that is often the companion of poverty; and HUGH STOWELL SCOTT ("Henry Seton Merriman") (b. 1863; d. 1903), whose novels, though essentially melodramatic, are characterised by a genuine gift of observation.

**Stevenson as a Novelist.** ROBERT LOUIS BALFOUR STEVENSON (b. 1850; d. 1894) crowded many activities into a short life and put a heavy strain on a physique by no means strong. As we have already seen, he essayed other walks than that of fiction; but it is as a novelist that he brought the greatest influence to bear upon contemporary literature. This influence was of a two-fold character. In the first place it was the influence of a writer for whom form was a dominating concern; in the second place the influence was that of one for whom the world was still young, and who, believing that to the young in heart all things are possible, succeeded by the exercise of his genius in reviving the latent spirit of romance. Stevenson was equally at home in dealing with the peculiarly horrible—witness "The Body-Snatcher" and "Dr. Jekyll and Mr. Hyde"; pure adventure, as in "Treasure Island," which first won for him the suffrages of a wide public, and "Kidnapped"; allegory, as in "Will o' the Mill" and "Markheim"; and the purely romantic, as in that haunting story of the South Seas, "The Beach of Falesá." In the serious work of novel writing, distinct from the short story, the phantasy, or the book for boys, Stevenson's gifts are seen at their best in "The Master of Ballantrae." "The uncompleted 'Weir of Hermiston'" is sufficient answer to those who may be inclined to attach any credence to the fear felt by Stevenson towards the close of his short life that his powers were deserting him. He was equally a master of the novel and the short story. Yet he is likely to be remembered in the years to come chiefly for his essays.

## HATTERS

A man's hat proclaims to the expert in hat lore his country, class, and the century in which he lives or lived. Fashions in hats are constantly changing, and in all ages there have been extremists who have either worn the most elaborate headgear or have gone bare-headed. Of late years it has been the fashion during the silly season to make a crusade against the silk hat, and yet it still continues to be the stamp of respectability and smartness. The workman and the sportsman may wear caps, but the aristocrat and the professional man alike appear in silk hats.

It is the duty of the hatter to cater for all classes, and as hats may fairly be considered a universal article of wear, it naturally follows that his business will flourish as long as he supplies the needs of the people. As a general rule, hats are sold by hatters and outfitters, as well as by many tailors, and there is no doubt it is a business that harmonises well with hosiery and general outfitting.

**Premises.** The hatter's premises should be centrally situated because, dealing in only one class of men's wear, he must be easy of access. A good window is essential, two are desirable, and there should be a fair amount of room in the shop interior. Hatters pure and simple are not numerous, but there are a goodly number to be met with in most cities and large towns.

There are many styles of conducting a business of this kind: for instance, a celebrated firm of hat manufacturers has opened a large number of branches in different parts of London to supply a large variety of hats at 3s. 9d. each, keeping nothing higher or lower in price.

As a general rule, however, it is found better to keep a general stock of the various kinds of hats and caps worn in the district at a good range of prices. In some few districts it is possible to make a good business from the sale of some speciality, such as, for instance, sporting styles, hats for riding, or boating, etc. Some retailers make a leading line of clerical hats, while others lay themselves out to supply those special styles worn at Court.

**Buying the Stock.** One of the most important qualifications for success is to know exactly the requirements of the neighbourhood, for the hats and caps sold in Whitechapel differ considerably from those required in Piccadilly. It has also been found that the

range of sizes required in one district varies from those of another, consequently our first and most emphatic advice is to know your prospective customers' requirements as regards size, style, and shape, and to buy accordingly. The hatter who wishes to do a good trade will find it necessary to stock many styles that cannot by any stretch of imagination be called fashionable, for there are always some men in every district who prefer the old styles. On the other hand, he will require a selection of the newest patterns, and in both of these there is a danger of making bad stock, so that at both ends of the range of style it will be well for him to buy as sparingly as possible.

**Classification of Stock.** His stock may be classified as follows:

**SILKS.** Fashionable styles, livery hats, clerical hats.

**STRAWS.** Various shapes, different plaits, assortment of prices.

**FELTS.** Hard and soft, various styles in each, coloured and black.

**CAPS.** Styles to suit districts. Good range of patterns and prices.

**SUNDRIES.** Hat-bands, hat-guards, pads, brushes, cockades.

The range of sizes generally runs from 6½ to 7½ for young men's hats, and 6¾ to 7¼ for older men's styles.

A very small selection of the extreme sizes suffice so that the dozen assortment would run as follows.

|    |    |    |    |   |    |
|----|----|----|----|---|----|
| 1  | 2  | 3  | 3  | 2 | 1  |
| 6½ | 6¾ | 6¾ | 6¾ | 7 | 7½ |

and for the 6¾ to 7 range when only a half-dozen of a kind are stocked, the sizes are assorted on the 1, 2, 2, 1 plan as, for instance:

|    |    |    |   |
|----|----|----|---|
| 1  | 2  | 2  | 1 |
| 6¾ | 6¾ | 6¾ | 7 |

For a medium class of trade the prices would range from 2s. 6d. to 6s. 6d. for felts, 8s. 6d. to 15s. for silks, 1s. 6d. to 3s. 6d. for straws, and 6d. to 3s. 6d. for caps. Of late years caps have come very much to the fore, and much higher priced caps are sold than was formerly the case.

**Hat Sizes.** As we have already stated, the usual run of hat sizes is from 6½ to 7¼, the particular size being found by measuring the length and width of the inside of the hat, adding them together and dividing by two.

## SHOPKEEPING

Stock sizes are made to the following dimensions :

| Size.           | Length.         | Width.          |
|-----------------|-----------------|-----------------|
| 6 $\frac{1}{2}$ | 7 $\frac{1}{2}$ | 5 $\frac{1}{2}$ |
| 6 $\frac{3}{4}$ | 7 $\frac{3}{4}$ | 5 $\frac{3}{4}$ |
| 6 $\frac{7}{8}$ | 7 $\frac{7}{8}$ | 6               |
| 6 $\frac{7}{8}$ | 7 $\frac{7}{8}$ | 6 $\frac{1}{4}$ |
| 7               | 7 $\frac{1}{2}$ | 6 $\frac{1}{2}$ |
| 7 $\frac{1}{4}$ | 7 $\frac{3}{4}$ | 6 $\frac{3}{4}$ |
| 7 $\frac{1}{2}$ | 8               | 6 $\frac{1}{2}$ |

The circumferences of the different sizes are as follow :

| Size.           | Circumference of head. | Circumference of hat. |
|-----------------|------------------------|-----------------------|
| 5 $\frac{1}{2}$ | 18 $\frac{1}{2}$       | 19 $\frac{1}{2}$      |
| 6               | 18 $\frac{1}{2}$       | 19 $\frac{3}{4}$      |
| 6 $\frac{1}{2}$ | 19 $\frac{1}{2}$       | 20 $\frac{1}{2}$      |
| 6 $\frac{3}{4}$ | 19 $\frac{3}{4}$       | 20 $\frac{3}{4}$      |
| 6 $\frac{7}{8}$ | 20                     | 21                    |
| 6 $\frac{7}{8}$ | 20 $\frac{1}{2}$       | 21 $\frac{1}{2}$      |
| 6 $\frac{7}{8}$ | 20 $\frac{3}{4}$       | 22                    |
| 6 $\frac{7}{8}$ | 21 $\frac{1}{2}$       | 22 $\frac{1}{2}$      |
| 6 $\frac{7}{8}$ | 21 $\frac{3}{4}$       | 22 $\frac{3}{4}$      |
| 7               | 22                     | 23 $\frac{1}{2}$      |
| 7 $\frac{1}{4}$ | 22 $\frac{1}{2}$       | 23 $\frac{1}{2}$      |
| 7 $\frac{1}{2}$ | 22 $\frac{3}{4}$       | 24                    |
| 7 $\frac{3}{4}$ | 23 $\frac{1}{2}$       | 24 $\frac{1}{2}$      |
| 7 $\frac{3}{4}$ | 23 $\frac{3}{4}$       | 24 $\frac{3}{4}$      |
| 7 $\frac{3}{4}$ | 24                     | 25 $\frac{1}{2}$      |
| 7 $\frac{3}{4}$ | 24 $\frac{1}{2}$       | 25 $\frac{3}{4}$      |

**Selling.** In selling hats it is often necessary to adapt the outline of the hat to the shape of the wearer's head, and as most hats are stiffened with shellac or other similar substance amenable to heat, it is possible to mould them by slightly warming them and then moulding them to the shape of the head, either by manipulating them by the hand, or by gently pressing them on to the head. Care must be taken not to heat them too much, or the effect will be seen in the brim, which will lose its shape. Sometimes it is necessary to stretch a hat ; some hatters do this by putting it over the knee and pulling it by the hand, but there is a danger of splitting it by this method. The better plan is to have a series of tapered blocks, and to force these into the opening, thereafter warming the hat slightly.

In addition to the regular sale of standard styles, a considerable business may be done in special orders, such as for school and club caps, hats and caps made to order, the supply of club ribands, etc., while special orders are continually cropping up which have to be made specially. Of late years these orders have been greatly facilitated, and it is possible now to get them through in from four to twelve days, whereas it formerly took twice that time. It is very desirable to do business with two or three good houses, one of which should be selected on account of the attention it gives to special orders. It is always well to keep a fully-illustrated price list handy, as orders of this kind are thereby better treated.

**Fixtures and Fittings.** The fixtures and fitting of a hatter's shop are of the simplest kind ; a light frame round the walls with openings

to take hat-boxes will suffice. Some hatters keep all of a style and price together, two or three in a hand-box, but others have special boxes made to hold from six to twelve of the same size. Both plans have features to commend them; the first makes it easier to sort up the stock, the second enables you to bring out an assortment before your customer without trouble.

A good mirror is an essential in the shop ; indeed, if anything like a business is done there should be two or three. Hand glasses are sometimes used, but more often wall mirrors are employed of a size sufficient to enable the customer to get a good view of himself. For the window a variety of hat-stands and brackets are desirable, and a good supply of suitable brackets. An atmospheric gas stove, a supply of hatters' irons and pads, some brushes and whisks, and a sliding hat measure, completes the special fittings required by the hatter.

**Profit.** The hatter's profits do not vary much from that of the ordinary retailer. Goods costing 8s. 6d. to 9s. per dozen are sold at 1s. each, articles costing 18s. 6d. to 22s. 6d. per dozen are sold at 2s. 6d. each, and so on, the minimum profit being 25 per cent. on returns. Trades that do a credit business necessarily charge higher prices ; on the other hand, club and contract orders are often supplied at a very low profit, it being looked upon as a good draw to the shop for other business, and there is no doubt that this view is right.

Most hatters undertake the pressing of silk hats, and although some do this free of charge to their regular customers, others make a charge of 4d. or 6d. for their services. Extra profits are to be made occasionally on special job lines, but as some of these are practically unsaleable, it is questionable whether the general average is higher than for regular stock. We conclude this article by noting the following points.

**Rules for Hatters.** The pile of hats always runs from left to right, with the brim towards you ; they should never be brushed against the pile.

Experience shows that measurements round the head are invariably taken too large, and it is much safer to take the inside measure of the length and width of the wearer's hat by the aid of a hatter's rule.

Keep your stock fresh by ordering frequently, sorting up sizes, rather than by buying large quantities, as stock of this kind soon gets out of condition.

Cockades are secured on the left side of the hat with a hairpin passed through the body of the hat and a cork placed on the inside of the hat.

Royal cockades are quite round, and made of flexible leather. Military cockades are oval and made of stiff leather and ornamented with a fan or comb. Naval and civil cockades are the same as the military, but without the fan. They are looked on as a fashionable adjunct of smart livery.

The terms of trading, advertising, and working expenses in the business of a hat retailer are similar to those of the clothier, the gentlemen's outfitter, and the glover and hosier, all of which are discussed in articles on these trades.

## HERBALISTS

The trade or profession of a herbalist is by no means dead. It flourishes exceedingly, particularly in the Midland and Home counties, and there are many snug livings in the business even at the present day. To be successful in it an instinct for herboristry is a qualification. This was more of a necessity in days gone by, when the dealer in medicinal herbs and simples grew his own stock, dried the plants, and sold them with or without incantations. In these more matter-of-fact times the business may be learned, like any other branch of shopkeeping, in the establishment of a herbalist with a good connection, wholesale or retail, or in a pharmacy, or drug store.

**Hallowed by Antiquity.** Although the origin of the "profession" may be hidden in the mists of antiquity, there is still in force an Act of Parliament which gives the practice of administering herbal remedies a legal sanction. In the third year of Henry VIII. an Act was passed giving permission to others than physicians and surgeons to administer certain medicines externally. This Act, which has never been repealed, shows little respect for doctors. It enacts :

That at all Time from henceforth it shall be lawful to every Person being the King's subject, having Knowledge and Experience of the Nature of Herbs, Roots, and Waters, or of the Operation of the same, by Speculation or Practice, within any Part of the Realm of *England*, or within any other the King's Dominions, to practise, use, and minister in and to any outward Sore, Ulcer, Wound, Apoplexies, outward Swelling or Disease, any Herb or Herbs, Ointments, Baths, Pultices, and Emplaisters, according to their Cunning, Experience, and Knowledge in any of the Diseases, Sores, and Maladies before said, and all other like to the same, or Drinks for the Stone, Strangury or Agues, without Suit, Vexation, Trouble, Penalty, or Loss of their Goods.

That this Act is still recognised is shown by the fact that in 1901 a herbalist in London, who was prosecuted by the Society of Apothecaries of London for an alleged infringement of the Apothecaries Act (acting as an apothecary), successfully convinced the county court judge, by virtue of the Henry VIII. Act, that he was quite within his legal rights in supplying remedies to poor people who came to him for advice. A curious survival of an ancient custom is still extant in London in that, on great occasions, the herbalists to the Corporation of London regularly supply aromatic herbs to be strewn in the Guildhall and in the Old Bailey as the traditional precaution against fever.

**Present-day Practice.** The herb-shop of to-day is much different, however, to that of even fifty years ago. For, except in some districts, the public nowadays prefer their medicines ready-made. The old plan of selling the real herb recommended for a specified complaint and of giving directions to the purchaser how to prepare it, has been superseded by supplying preparations of the herbs in the form of tinctures, fluid extracts, pills, lozenges and even tablets. There are also packed herbs and

herbal preparations of all kinds supplied by wholesale dealers, so that the place has usually more the appearance of a chemist's shop than anything else. The modern herbalist does a considerable amount of prescribing for simple maladies, but he must be careful not to trench on the domain of the apothecary or of the doctor; and his remedies must, of course, be non-poisonous, as by selling scheduled poisons he would bring himself within the purview of the Pharmacy Acts. There is plenty of scope for the careful man, with a genuine knowledge of the properties of herbs and simples, to do a legitimate and lucrative business without treading on dangerous ground.

**Capital and Start.** With a knowledge of the business and a capital of about £100, a very fair start may be made. The best kind of neighbourhood to select is that populated by the working classes. The business is a personal one, and the herbalist must have the ability to please and to gain the confidence of his customers, as well as an intimate knowledge of the medicinal properties of his goods. A ready sympathy and an intelligent interest in the domestic cares that worry the households of his neighbours go far to build up a connection; but discretion in prescribing for simple ailments, and the knowledge when to advise the more skilled treatment of the medical practitioner are very requisite. A shop in a busy street should be selected. A single-windowed shop is quite big enough for a start, and it would be fitted up with shelving, a closed-in window, and cases and drawers in a similar style to that of a chemist. The beginner would, of course, avoid opening in the proximity of an established chemist, whose wares are naturally somewhat of the same order. A number of shop rounds and glass jars are necessary for storing the liquid preparations, ointments, powders and so forth now affected by the herbalist; and tins should be bought for storing the herbs, roots, etc. Enamelled tins, square, with hinged lids, to hold 1 lb. of crude drugs cost about 7d. each; 2 lb., 9d.; 3 lb., 10d.; 4 lb., 1s. 1d. The fittings, all told, should not cost more than £30 to £40, and many useful hints in this particular will be obtained by referring to the article on Chemists and Druggists [page 1651].

**The Herb Stock.** The mainstay of the man we have in mind would be his herbs. For an opening order, therefore, he would select 7 lb. quantities of each of the following herbs: Balm, broom, camomile, centaury, dandelion, ground ivy, hops, horehound, hyssop, parsley-piert, pennyroyal, rue, southernwood, tansy, bearberry, and yarrow. He would also buy similar quantities of juniper berries, marsh-mallow leaves, and quassia wood. Smaller supplies—say two pounds to four pounds of each—would likewise be needed of the herbs of agrimony, angelica, arrach, avens, bittersweet, blue mallow, boneset, brooklime, buckbean, burdock, clivers, cranesbill, cudweed, dog's grass, eyebright, feverfew, fennel, figwort, fumitory, germander, golden rod, hart's tongue, heartsease, ladies' mantle, liverwort, lungwort,

meadow sweet, motherwort, mountain flax, mouseear, mugwort, mullein, nettles, pellitory, peppermint, pilewort, redsage, rosemary, sanicle, self heal, scabious, shepherd's purse, scull cap, sourvy grass, soapwort, speedwell, spigelia, vervain, wood sage, wild carrot, wood betony, woodruff, and wormwood. Like quantities are required of the barks of barberry, bayberry, cascarrilla, oak, poplar, and sassafras, of the leaves of blackberry, blackcurrant, box, buchu, colts-foot, comfrey, ground pine, raspberry, senna, and bearberry, and of the roots of blue flag, burdock, calumba, comfrey, cranesbill, dandelion, elecampane, gentian, liquorice, mandrake, marsh-mallow, red dock, sarsaparilla, tormentilla, valerian, and yellow dock. An outlay of about £10 would suffice for the foregoing.

**Preparations.** So much for the crude herbs, but nowadays much more is required. Liquid preparations of many of the herbs mentioned, in the form of fluid extracts, tinctures (simple and compound), and mixtures must be stocked. A small quantity of each would be purchased ready-made from a reputable wholesale drug house. The fluid extracts of cascara, cinchona, camomile, coca, damiana, fucus vesiculosus, golden seal, etc., would be bought in quarter-pound quantities, and half-pound or one-pound quantities of the more commonly required tinctures, such as aloes, benzoin compound, calumba, capsicum, cardamoms, catechu, chiretta, cinchona, digitalis, gentian compound, ginger, compound lavender, lobelia, myrrh, paregoric (without opium), quassia, quinine (simple and ammoniated), rhubarb compound, serpentary, senna, stramonium, valerian, etc., would have to be bought. In the selection of these things, as well as compound powders—like liquorice composition powder, etc.—the beginner would be guided by his experience, by his knowledge of the probable requirements of his neighbourhood, and by the amount of money he had to spend. A small supply of the pills usually in greatest demand (colocynth, rhubarb, aloes and asafetida, blue, and so forth), of ointments, like zinc, boric acid, gall, spermaceti, cold-cream, white precipitate and red precipitate, had better be secured until the owner has time to make his own stock of galenicals, if he intends to do so. All the official preparations of the Pharmacopœia and many unofficial formulas are now supplied by wholesalers on terms which make it scarcely worth while for the busy man to make his own. It is advantageous in a personal business like a herbalist's, however, to be able to produce preparations, pills especially, that are undoubtedly his own make. Lozenges are a rather important item with herbalists, and a stock of considerable variety should be kept, digestive tablets, blood tablets, cough tablets, throat lozenges, worm lozenges, and others being an everyday demand. As the business grows the lozenges might be augmented by supplies of candies (composition, borehound and aniseed, pepsin, etc.), pastilles, and jujubes. The preparations named, carefully selected and not bought in too large quantities at first, would cost another £10 to £15.

**Packed Goods.** To make a brighter show, another \$5 might be expended on packed herbs and herbal remedies. Sweet herbs for culinary purposes would have to be kept either loose or in packages. Bay leaves have quite a vogue in many Lancashire and Midland towns for cooking herrings. Other necessary sweet herbs are basil, marjoram, mint, parsley, sage, savory, tarragon, and thyme. Then there are packages of mixed herbs for preparing homemade tonics, herb beer, herbal smoking mixture, blood purifiers, fomentation herbs, and so forth. A perusal of the illustrated price lists issued by the wholesalers will help the beginner to secure an attractive series of packed proprietaries, all of which help to fill up the new shop and to attract custom, while the profits even on proprietaries are not to be ignored. The profits on the better known and more widely advertised patent medicines are scarcely tempting enough to induce one to lay in a big stock of them, but as the business progresses a supply of these will probably be found requisite, as well as of the more generally used druggists' sundries, such as feeding-bottles, enemas, breast exhausters, hot-water bottles, and tooth-brushes.

**Profits.** If the beginner has the elements of a good business man, if he knows his business thoroughly, and attends to it strictly, he need fear little for his pecuniary reward. The profit on herbs is considerable, and it is only a question of turnover. The stock of herbs indicated as of everyday sale in a previous paragraph will cost an average of about 6d. to 8d. per pound, and the retail price is usually 1d. per ounce. This means a profit of 100 per cent. on cost price, but it must not be forgotten that the sales are usually small, pennyworths predominating. The preparations, liquid extracts, tinctures, etc., should be sold at an average profit of about 50 per cent., and when the sundries, with much smaller profits, are taken into consideration an all-round average of probably 33½ per cent. on the turnover will be secured. This should be sufficient to pay a £20 to £30 rent, taxes, and other necessities, and leave a fair net profit on the capital invested. A reputable man will have no difficulty in securing three months credit from the wholesale herbalists, of whom there are many in London and the country. Carriage is often paid on wholesale orders over £2.

**Aids to Development.** The adventitious aids to the development of the herbalist's progress are mainly in the way of advertising. The up-to-date man keeps his wares before the public by means of pamphlets, handbills, and a small advertising space in the local newspaper. Smartly written bills telling all about seasonable lines should be distributed freely and periodically in the neighbourhood. For his own use he will have copies of such useful botanical books as Potter's "Cyclopaedia of Botanical Drugs," 2s., published by Potter and Clarke, Artillery Lane, London, E.; Slack's "Herbal," 4s. 6d., obtainable from the same firm, and Squire's "Companion to the British Pharmacopœia," 12s. 6d., published by J. and A. Churchill, New Burlington

Street, London, W. There are a variety of other books which the enterprising herbalist may in time find it profitable to stock and to sell, such as Robinson's "Family Herbal," 2s. 6d.; Stevens's "People's Guide to the Botanic Treatment of Disease," 2s.; "Culpeper's Herbal," 10d.; "Health for the People," 5d., and many others.

### HOUSE FURNISHERS

To a young man there are few trades affording such excellent opportunities as that of general furnishing. Of course, some capital is necessary, but brains are more so, and, given plenty of grit, there is no reason why success should not be attained. No better experience can be gained than that of working through the various departments of some of the very large firms. There, by constantly watching the value of goods—for nowadays nearly every dealer marks the goods in private figures, which are known to most of the employees—the assistant may acquire a general knowledge which will prove eminently useful when the budding shopkeeper starts on his own account. The department which calls for most careful study is the carpet section, for it is only by constantly handling carpets and rugs that the fingers get so sensitive that clever buyers are able to judge these goods so exactly and closely that the small difference of  $\frac{1}{2}$  d. per yard in quality is noticeable to them. The retailing of carpets is discussed in a separate article [page 1625].

**Premises.** Let us now assume that a small shop in one of the suburbs is found, where the rent does not exceed £60 per annum, in which to commence business. What amount of capital is required to stock the shop nicely, and what goods should be placed therein? Well, let us answer the question of capital first. It is much better if the capital be small, for one must remember that the beginner, hitherto an employee, and having had someone to guide him and tell him what to do, will now have to decide the hundred and one things for himself, not only as regards buying and selling, but many things which a servant always refers to his superior. Consequently many mistakes will at first occur; these mistakes will cost money, but experience thus bought and paid for is far better than any advice that can be read in books.

**Stock.** We shall assume that £250 is at the disposal of the beginner—not a large amount, it is true, but far greater than many merchant princes of to-day started with. The first consideration must be that of fixtures. Just a few are absolutely necessary, such as gas fittings, sun-blinds, etc.; the bedstead, bedding, and fender racks must follow later. The question of stock must next be very carefully considered, and a visit paid to the manufacturers, where goods, after a careful inspection, are ordered, the beginner ever keeping in mind that with his modest capital, he cannot afford to buy expensive goods, for they may remain in stock longer than he may expect, but only goods that are wanted every day, such as all classes of japanned bed-room wares. These things cost comparatively

little, but are very effective for making the shop look well and fully stocked. This "well-stocked" effect is a most important point, because people are almost always shy about entering a shop which is not well stocked, even to inquire about a price. Again, in buying upholstered goods, it is just as well to keep in mind that the easy-chair you can retail for 16s. 6d., 18s. 6d. or £1 1s. will sell easily, while those at £5 or £6 may remain in stock, get spoiled, and finally be unsaleable. The customer who wants the higher price class of goods wants a larger selection from which to choose, and hence will go to the tradesmen who especially cater for this class of trade. The stock must be selected so as to include cane, stuffed seat, and Windsor chairs, kitchen, dining, and small occasional tables; about a dozen bedsteads, mostly 3 ft. and 4 ft. wide, cornice poles (bamboo and stained mahogany), with the necessary brackets, etc.; Japanned and veneered mahogany and walnut chests of drawers, wire spring mattresses (upholstered springs have gone out of fashion), kitchen, bedroom, and three or four brass-rail fenders, fire-irons and brasses, made-up tapestry or hemp carpets with a piece or two of  $\frac{3}{4}$  (18 inches) or  $\frac{5}{8}$  (22 $\frac{1}{2}$  inches) stair carpet, a few rugs, Axminster, and black and white goatskin rugs, and a roll or two of linoleum. Of glasses, he must have dressing-table mirrors, cheap bamboo and walnut overmantels. He will also have to select a few cheap fancy suites of five pieces, with perhaps a saddle-bag suite and one or two couches; this, together with a few toilet sets, will give a fair selection of goods.

**The Window.** Now that he has filled the shop, the next step is to dress the window, and possibly to make a show outside. The latter is often a good way to make a stir and assist the turnover. Tickets, bearing prices, must be used so as to induce passers to stop and look. They should be easily read tickets and neatly printed. Keep to one scheme of card—colour, style of lettering and colouring—and have your name on each large card. This helps to characterise and advertise your establishment. At this point let us add that the time spent in dressing a window is not time wasted, for if this part of the work be done thoroughly, it will be found that the man or woman passing the shop daily will look to see what fresh attraction has been made; and thus will far better results be secured by repeated changes. For example, during the first part of the week have a complete bed-room fitted up; for the latter part, a drawing-room display followed by a dining-room exhibit. This may be succeeded by a combined bed-sitting-room display, and it will soon be found that this extra trouble is well repaid.

**Buying.** It will be found that with some houses credit is not difficult to obtain if the retailer has a good name in the trade. This credit usually means that the goods are duly delivered, and on the following tenth of the month a statement is rendered, from which may be deducted 2 $\frac{1}{2}$  or 3 $\frac{1}{2}$  per cent. for prompt cash. Payment in a bill at three or four months' date will lose the discount, but these terms must

always be arranged at the time of opening the account. Now, of the two methods here given for payment which the beginner may take advantage of doubts will necessarily arise in the mind as to which method is the better. And let us say at once both methods are necessary, or will be when the business gets larger; but, for a start, it is much better to pay cash, for the goods will be bought in the markets of the manufacturers, many of whom are very small makers, and thus the buyer will save the factors' profit, a very important matter in these days of keen competition when the public—we allow they do not know so much about the trade as yourself—are sharp enough to go round comparing prices with your larger competitors, and will certainly buy in the shop where prices are lowest.

**Cash in Hand.** Now we have spent in stocking the shop at least £150; another £10 has gone in fixtures, fittings, window-tickets, etc. You may say, "But surely I do not require £90 lying idle at my bank?"—for we presume you will arrange to have an account open at your local branch of some big bank, who may charge you £2 2s. or £3 3s. per annum for keeping your account; and, let us record how important it is that care be used in selecting your bank, for probably you will bank at that place for the rest of your business career. This may seem a small detail, but it is a very important one, because all questions of credit—as to whether you are worth trusting or not—may turn on the reply your bank manager gives to the question that is put through by the wholesale trade when inquiring about your stability in the commercial world. However, we are digressing somewhat from that £90. Trade will not come in quite so fast as you in your optimistic flights of fancy have imagined. It is very possible that during the first week, or even the first six weeks, you will take no more than £10 to £20 per week at the outside. You, and those dependent upon you, will have to live, and it is the first twelve months that needs the greatest care in seeing that the cash you draw from the business is as small as possible, for do not imagine that you are going to earn from two to three hundred per annum with your capital; and hence the advisability of having a reserve on which to fall back.

**Making a Connection.** Still, do not be disheartened, for, although you are not making a lot of money, you should be making a connection among customers who will always be coming to you for little oddments; and do not be too proud to go to your customers' houses to fix up a cornice-pole or a bedstead. It is the extra attention that you can give your customer that will tell in your favour when he has a large order to bestow.

Then, again, you will occasionally find you have tendered goods to people you can trust, and it may be advisable not to ask them for your cash till the end of the month, when you know the breadwinner gets paid. Then is the time that your spare cash proves of tremendous value—in that it enables you to wait; or you may

deliver part of an order, the balance of goods you have to get made. In such cases you will show poor business qualities if you ask for the cash before you complete the order. Moreover someone may come in and want to sell some second-hand goods, because leaving the neighbourhood. A spare £10 note in such cases will probably purchase goods that will realise £20 afterwards. Such plums do not fall to the man who has all his capital locked up in stock.

**Profits.** The profit on new stuff must be fairly uniform of about 33½ per cent. (6s. 8d. in the £) to 40 per cent. (8s. in the £) on cost price, with, perhaps, an extra 5 per cent. on china to allow for breakages. The next very important point to consider is that of accounts. The state of your affairs ought to be apparent at a glance, for you must remember that nearly all small failures occurring in this country are due to carelessness in bookkeeping. The latter word, "bookkeeping," is a veritable bugbear to many; but let us be very candid in this matter, as it is positively dangerous to trade without a proper set of books. They should be of a very simple nature—such as a "day book," to enter all goods that are sent out; a "cash book," for all receipts and expenses; and an "invoice book," for all goods that come in; these must be posted regularly into a ledger. All goods coming in should be entered in your stock book, and those going out deducted from it. Every article, as it comes, should be ticketed with at least its cost price—from which you will, at a glance, see what price to ask on inquiry from a customer without having to turn to your stock book or your invoice; better still if the article be numbered as well, for this will make it easier for you to "mark back" your stock book. The question, whether all goods should be marked in plain figures, is one where we would not advise where practically all sales will be made by yourself, and where a certain amount of exchanges are being made; but, undoubtedly, where the business is of such a size as to permit of the employment of a salesman, it is one of your safeguards to make sure your profit is maintained. It is vitally necessary that this should be done and rigidly adhered to.

**Hire-purchase System.** We cannot imagine a man with a small capital attempting to run a shop by sales on the instalment or hire-system plan, for undoubtedly it would end in disaster; but it may not be out of place to refer to the hire system here. Those who have placed their business on a secure foundation, and feel a capacity and a wish to increase their trade and invest surplus capital, may justifiably sell on easy terms; but in such cases infinite care must be taken to be sure of the reliability of the person to be trusted with goods. Even greater care will have to be taken with all entries in the books—a system of inquiry as to the status of the individual wanting the goods, means by which defaulting customers can be pressed for the instalments, and also a system for tracing "runaways." Although larger figures due to increased profit from this class of trade may look well in your day books, please

do not reckon it as *all profit* until you have collected the cash. However, space will not allow an attempt to fully deal with the hire system further, beyond stating that large fortunes have been made by this system by men who have grown up in the trade. We are certain that many men who have attempted to follow in their footsteps have failed in their endeavours, and lost all their capital through trying to run before they had learned to walk. Do not think we are trying to deter anyone from adding a credit system to their ordinary business, a system which, if conducted in an honourable manner, will help to build a business of which its possessor will be proud. But learn this part of your business thoroughly before launching out to any great extent.

**Advertising.** Lord Macaulay wrote "that advertising is to business what steam is to machinery." This, although written in the days when advertising was in its infancy, is as true now as it was then, and to realise this you have only to look at the daily press to see the amount of money spent by the furnishing trade on publicity. You will then be convinced that the firms spending big fortunes every year on advertising their business are the firms doing the largest and the most profitable trade. If you are going to succeed, you will have to work more hours in your own business for some years than ever you were asked to work by an employer. And, added to your numerous other duties, you will have to study the advertising problems, not in any half-hearted manner, but with your whole heart—other men have done it before you and are doing it to-day, and although the amount of your capital to spare for advertising is small, the more reason why you should spend that amount wisely and well, so as to produce the greatest amount of good to your business. You may fancy the public are fools and are easily gulled. If you do think so, pray eradicate that fallacy from your mind at once, and as quickly as possible appreciate the fact that the public much prefer to deal with a smart, honourable man of business than a fool or rogue; and the only way to let them know you are a smart man is by advertising in some way or other that the goods you have to sell are at the right price, the right quality, and that you are the man to whom they must come if they want to be right up to date in the furnishing of their house.

**Channels of Advertisement.** Two methods are open to you—by using your local papers, and by handbills distributed from door to door. Both of them ought to be used. Your local paper should especially be used if it shows the interest in local matters it should do. Change your advertisement in the papers every week, and write in a racy manner, so that the readers will look for your advertisements

as they do the reading matter of the paper. Handbills, if judiciously distributed, will help to catch those people who do not take in the weekly local paper. Why we lay such stress upon advertising is because it is not possible to make a large business without it. One instance that we have in mind is that of a man in the furniture trade who devoted all his previous year's profit—about £500—to advertising, and so successful was he that within ten years he was spending over £20,000 per annum in newspapers alone, until he had made a name for himself throughout England for a speciality that even his mail orders alone each morning required a large staff of clerks. We cannot imagine that he spent the latter sum out of his profits without reaping some benefit himself, and yet that man started in business forty years before with not more than a five-pound note.

**Trading Results.** Following the lines laid down, how often ought the capital to be turned over in the first year? Well, we think the first year should show a trade of about £20 to £25 per week, or £1,000 to £1,300 per annum; in other words, the capital should be turned over about four or five times. If this be done, the gross profit ought to be about £350 to £400. Do not get confused with the words "gross" and "net" profit; the former means the profit before the expenses are deducted, and the latter after the expenses have been taken off. Therefore, to be deducted from the £350 gross profit will be the rent, £60, together with rates, taxes—this will be, say, £100; gas and repairs, £25; advertising, £25; lad's wages, £26; various sundry expenses, £10; total £186. In addition to this amount, something must be allowed for your own living, which may be £80, but should not exceed £104—let us say the latter, which will make £290, and will give you a margin of £60 to add to your capital in hard cash or increased stock; but, in addition to this, if you have conducted your business properly, you will also have added something better than cash, but which will not show in your balance-sheet, namely, a nucleus of a trade which will be constantly increasing. Regular customers gained by this practice will cost very little for advertising, save an occasional circular or card, or, better still, a call from yourself. In addition, if you have given satisfaction, customers will always be pleased to recommend you, and an intending purchaser who is recommended to your shop is always easier to serve than one who is attracted solely by your window show or one of your advertisements.

It is certain that if you follow these precepts and are prepared and determined to work hard and give all your time to the care of your business, it will not be many years before you are the proprietor of a business employing many other hands besides your own.

# NORTHERN AFRICA

The Nile Floods and Course of the Nile. Its Value to Egypt. Abyssinia. British and German East Africa. The Niger and West Africa

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

**The Source of the Nile.** The true source of the Nile is the Kagera River, which rises considerably south of the equator at a height of over 6,000 ft. in the highlands overlooking Lake Tanganyika. In 350 miles it falls over 2,000 ft. to Lake Victoria Nyanza, round the northern half of which lies British East Africa. The great lake is set among hills, and above its waters rise many wooded islands. Its reedy banks are the home of the hippopotamus. Where it leaves the lake, forming Ripon Falls, the Victoria Nile is half a mile wide. It descends the northern slopes of the Central Highlands, gently at first, but afterwards in a series of cataracts and rapids, to Lake Albert Nyanza, 1,500 ft. below. This lake is fed by the Semliki, which has risen in Lake Albert Edward Nyanza, 1,000 ft. above, and flowed down beneath the snows of Ruwenzori. The Albert Nile, after leaving the lake, continues to fall, at first gently, and then with many miles of foaming cataracts.

**The Nile in the Sudan.** Near Lado the Albert Nile enters the vast plains of the Sudan, where its character changes. It begins to wind, and to broaden out into swamps which form immense lakes when the river is high. In this part of its course it divides into two branches—the Albert Nile, and a right-hand branch, the Bahr Zeraf, which later reunite. Both are liable to be choked by sudd, or blocks of living vegetation. "These blocks are formed of papyrus, weeds, and water-grasses, which grow on the half sandy, half peaty banks of the lagoons and marshes traversed by the river, and, under the action of a rising flood and strong winds, are torn up and driven into the channels wherever these are confined in width, and there jammed into solid masses of floating weeds, filling the whole width of the river, and very nearly the whole depth." Navigation is, of course, impossible. Since Britain held the Sudan, most of the obstructive sudd has been cut away, but it tends to re-form. Across similar country comes in the Bahr Ghazal from the west, in appearance resembling a swamp rather than a river. Below the junction of the Sobat from the east the two branches reunite, becoming known below the confluence of the Sobat as the White Nile.

**The Sudan.** The Sudan extends from the confines of Egypt southwards into the tropical forest area, which covers much of the Bahr Ghazal basin, supplying rubber, etc. The forests are replaced to the north by grass lands, which extend on either side of the Nile swamps, passing gradually into poor grass lands covered with tall, coarse grass, and still further north into desert. Khartum, the capital of the Sudan, is on the

margin of the desert region. The cultivated lands lie round the rivers. Millet and pulses are the staple crops.

**The Blue Nile.** At Khartum the White Nile unites with a tributary of very different character, the Blue Nile, the main source of that fertilising mud out of which Egypt has been built up. It rises near Lake Tsana, about 9,000 feet above the sea, in the volcanic highlands of Abyssinia, the scourings of which are swept down to the main stream by the tropical rains of summer, and whirled along by the foaming river to be spread out over the plains of Egypt thousands of feet below. After leaving the forested highlands of Abyssinia, the Blue Nile enters the plains of the Sudan, of which it drains the most fertile part. Millet, cotton, and wheat are grown, and the region will doubtless become a great wheat land.

**The Nile Valley.** Below Khartum the Nile flows in a gorge cut in the Sahara plateau, which is highest along the western shores of the Red Sea. In this part of its course it forms six cataracts. Between the sixth and fifth it receives the Atbara, which has risen near the Blue Nile. It is a wild river in flood, but for two-thirds of the year is reduced to a string of pools. Just above the Fifth Cataract is Berber, with a line to Port Sudan, near Suakin, on the Red Sea, making Egypt independent of the Suez Canal in war.

The Nile enters Egypt near Wadi Halfa, a short distance above which is the Second Cataract, extending over 124 miles. At the foot of the First Cataract is Assuan, where a great dam has been built across the river. The Nile in Upper Egypt flows in a narrow valley, bordered by cliffs or hills, formed by the edge of the Sahara plateau. Where these approach the river closely the scenery is picturesque. Cairo, the capital of Egypt, near the famous Pyramids, is built at the apex of the delta. Below it the river divides into the Rosetta and Damietta branches, with dams across both for irrigation purposes. Along the Mediterranean are a number of lagoons, some entirely landlocked. The surrounding country is marshy and unhealthy. The port of the Nile is Alexandria, 35 miles west of the Rosetta branch, founded by Alexander the Great.

**The Nile Floods.** For thousands of years Egypt has watched anxiously the rise and fall of the Nile. All through the hot months of early summer the river falls, and its waters become green and offensive. The coming flood is felt first far up the river, where the Abyssinian tributaries begin to pour in their mud-laden waters. At Assuan the Nile begins to rise in May, but the

brown muddy waters do not reach Cairo till the beginning of June. The Nile is highest at Assuan in the middle of September, and at Cairo early in October. The Atbara has run dry by the end of September, the Blue Nile is falling rapidly, and the main stream falls slowly but steadily till the anxious season of low Nile comes round again. A tardy rise of the river causes almost as much anxiety in Egypt as a delayed monsoon in India, so close is the connection between water and fertility in these hot lands.

**Methods of Irrigation.** Egyptian irrigation is of two kinds—seasonal and perennial. The former utilises the flood waters of the Nile, the latter its permanent flow. The basin system of irrigation has been in use for 7,000 years. In the narrow valley of Upper Egypt dykes about 10 ft. high are built parallel to the river, with cross dykes to subdivide the enclosed area. At high Nile water is admitted to these basins by shallow canals, allowing 4 ft. or 5 ft. of water to cover them. The villages, built on mounds, stand above the level of the flooded country. After six weeks the surplus water is drained off by escape canals, and the saturated soil, covered with newly-deposited fertile mud, is fit for cultivation by the end of November. This is a simpler method than perennial irrigation, but land so irrigated produces only winter crops.

Perennial irrigation is a modern system. The river is dammed back at suitable points till it becomes very deep, and water is drawn off above the dam to fill great canals, which feed a network of smaller ones. One dam has been built below Cairo, enabling the delta to be permanently irrigated, and another at Asyut, to irrigate Upper Egypt. They are fitted with sluices, which are opened in flood, when water is abundant, but shut down as the river begins to fall. The gigantic dam at Assuan,  $1\frac{1}{2}$  miles

long, with 100 sluices, was built to regulate the supply of water to the lower reaches of the Nile. It forms an immense reservoir, which is fed out as the Nile falls, keeping the river level high enough to supply the perennial canals of Upper Egypt and the Delta. The extension of permanently irrigated and therefore permanently fertile land by these engineering works is one of the

great boons which British rule has conferred on Egypt.

Besides these elaborate methods, primitive ones are also used, especially in high lands near the river. Water is raised by steam pumps, by the *sakieh*, a water mill of cogged wheels turned by an ox, and working up a series of pitchers which empty into a trough, or by the hand-worked *shadoof*—a simple contrivance for raising and lowering a bucket.

**Cause of the Nile Floods.** The cause of the periodic rise and fall was long a mystery. The explanation is simple. The equatorial lakes and the rivers which discharge them provide the permanent flow of the river as we have it at low Nile. The flood waters are brought by the Abyssinian tributaries, and especially the Blue Nile, after the tropical summer rains on the Abyssinian plateau.

**Egyptian Crops.** Egypt is often said to have three seasons, summer, flood, and winter. In summer the Nile is low, and cultivation is confined to the perennially irrigated lands, on which are grown cotton, sugarcane, millet, rice, fruit and vegetables. In flood the basin lands are submerged, and all the canals are full. The crops are millet, maize

and flood rice. Early winter sees the basins uncovered and the earth everywhere abundantly moist. Nearly all the country is now under cultivation. The crops—cereals, clover in the basins, pulses and vegetables—are sown in October or November, and reaped the following spring.

127. THE BASIN OF THE NILE

Of Egyptian crops cotton is the most important. Egypt is third among cotton-producing lands. And the crop is a summer one, grown both in Upper and Lower Egypt. There are many ginning mills but few cotton mills as yet. Sugar

along the bottom of some gigantic crack in the earth's surface with a nearly tropical heat; at another over some wind-swept plateau with a climate like that of England in winter. Every sort of vegetation is met with, the warm, low valleys

growing tropical plants, while on the wind-swept uplands the flowers and grains will be of an Alpine nature. Within a few hours' march are found the banana, grape, orange, pomogranate, peach, apricot and blackberry, the dhurra, maize, wheat, barley, peas, and the chili, pumpkin, tomato and potato. The villages are generally on heights, and the keeping of animals is important. Minerals, including gold, are known to be abundant. The capital shifts as the supply of firewood becomes exhausted. The trade centre is Harrar, near the Somali frontier.

**Eritrea, the Horn of Africa.** This is occupied by the Italian colony of Eritrea to the south-

west of the Red Sea, and by French, Italian, and British Somaliland. All consist of a coastal plain, behind which rises the plateau. The inhabitants depend chiefly on their camels and other animals. Jibuti, in French, and Berbera and Zaila in British Somaliland, are the chief settlements.

**British East Africa.** British East Africa lies partly in the Nile basin. It ascends by a series of steep terraces from the coastal plain to the plateau, much of which consists of boundless grassy plains occupied by pastoral tribes. It is crossed by the eastern Rift valley, with its chain of lakes, and contains the great cone of Kenia. Uganda lies between the eastern and western Rift valleys, and contains the great Victoria lake. The banana is the chief food tree. A railway has been built from Mombasa, on the hot, fertile, malarial coast, to Port Florence on the Victoria Nyanza, on which is also Entebbe, the chief British settlement. Zanzibar, consisting of the islands of Zanzibar and Pemba, is British territory governed by a native sultan. Cloves are the chief product. Zanzibar is the most important port and commercial centre of East Africa.

German East Africa resembles British East Africa, but is drier. It extends from Lake Tanganyika to the coast, and from Lake Victoria to Lake Nyasa. The chief port is Dar-es-Salaam.

**West Africa.** Between the Western Sahara and the Gulf of Guinea lies a vast region drained to the Atlantic by the Senegal (950 miles) and the Gambia (600 miles), and to the Gulf of Guinea by the great Niger (2,600 miles). The northern part of this region, a plateau of moderate elevation, is a savana land forming a

## MEDITERRANEAN SEA

128. THE DELTA OF THE NILE

is grown in Upper Egypt, where sugar factories are numerous. The cultivation of cereals will doubtless increase with irrigation. Egyptian lentils are famous.

**Oases of Egypt.** In a sense Egypt is itself one great oasis. West of the Nile valley are several oases in the desert, resembling Tafilet in general character. The Fayum, a depression in the Libyan hills, anciently received the surplus waters of the high Nile through a natural channel. It is thus formed of Nile mud. It is sometimes classed as an oasis, but it is irrigated from the Nile, and not like the others, from springs.

**The Suez Canal.** The Suez Canal across the isthmus is 87 miles long, of which 21 miles consist of natural depressions, now lakes. The Mediterranean port is Port Said, with long sea walls to prevent its silting up from the Nile. In the centre is Ismailia, the railway junction for Cairo, supplied with fresh water from the Nile by canal. Suez is the Red Sea port. The tolls for passing through the Canal, which reduces the distance to Bombay by 5,000 miles, may amount to thousands of pounds. Britain is a large holder of Canal shares. East of the Canal is the mountainous peninsula of Sinai, geographically part of Arabia, politically part of Egypt.

**Abyssinia.** Abyssinia is a volcanic plateau averaging 8,000 ft. in height. The surface is diversified with isolated peaks and ranges of fantastical shape, and in many parts rent by great ravines, which make it very inaccessible. The climate and products are as varied as the surface. At one part of the day travel is

transition between the arid desert to the north and the densely forested coastal lowlands of the Gulf of Guinea. This savana land, the Sudan, extends as far east as the Nile. The Nile provinces of the Sudan have already been described. The Senegal and Gambia rivers rise in the forested Futa Jallon highlands, and flow north-west, forming falls in their descent from the plateau to the lowlands, which are less densely forested than those of the Gulf of Guinea. The exports are ground nuts and rubber.

#### Difficulties of West African Trade.

Two great difficulties hinder trade – the want of harbours and the want of roads. Freetown has a good harbour, but from there to Old Calabar, a distance of 1,500 miles, the coast is beaten by the heaviest surf of the world. "Off every beach is a fringe of parallel thundering rollers, white-crested and steep-sided, smiting the sand with tremendous force." Every river has its thundering bar, "which it is almost certain death to cross except in boats constructed for the peculiar work, or in native canoes." Every pound of goods has to be shipped or landed through this fringe of breakers, and ships ride at anchor a mile or so from the shore.

Roads in the forest country are mere tracks, unfit for wheeled carriage. Human carriers are employed at a cost of time and money which is prohibitive to trade on a large scale. The cost of carriage in Northern Nigeria is 2s. a ton a mile.

**Swamps of the Niger Delta.** Between Lagos and the mouth of the Old Calabar River lies a waste some 400 miles long "of festering mud and slime, out of which the leather-leaved mangroves grow. Through this desolation of rottenness the waters of the Niger find their way to the sea by innumerable channels, the whole bound together by a network of tangled waterways." Of several hundred mouths only eight or nine are navigable by large vessels, though a steam launch with a native guide might doubtless travel through 500 miles of swamp and forest by as many different routes. Akassa, at the mouth of the main stream, has a dangerous bar at the entrance.

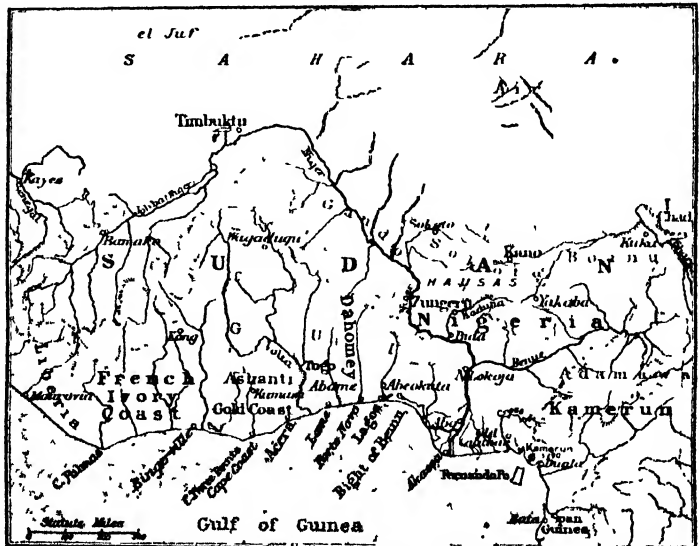

This region is almost impossible of habitation. Away from the fringe of forest along the creek the traveller sinks deep in the evil-smelling, slimy ooze, above which rise the distorted, stilt-like roots of the mangroves. Towards the apex the abundance of oil palms tempts the almost fever-proof native to brave the diseases of this uninviting region, which is yearly inundated by the flooded river.

The oil palm will not grow more than a certain distance from the sea, and loves a swampy soil. Its fruit resembles a fir cone or a pineapple, and contains many nuts, each something like a yellow plum. The nut contains a mass of fibre and yellow grease, and when boiled down produces the palm oil of commerce. The natives use it as we use butter. Enormous quantities are exported to Europe for soap and candle making, and to lubricate railway carriage wheels.

**The Lower Niger.** Not till Abo, 100 miles from the sea, is the Niger confined to a single channel. Above Abo it is a noble river, flowing between forests which contrast agreeably with the horrible swamps of the delta. Crocodiles and hippopotami disport themselves in the sun, and the banks are dotted with many palm-shaded villages, each with its thatched garden of yams, which form the staple food. The forest native tribes have many cruel tribal feuds and many savage religious practices.

**The Ascent to the Plateau.** Some 200 or 300 miles from the coast the country begins to rise into hills, which are the southern margin of the plateau from which the Niger comes down. The river flows between flat-topped mountains, rugged and bare, its fierce current swirling round the islands and rocky barriers, which impede its descent to the forested lowlands. The navigation of this part of the Niger is beset with dangers, but at last Lokojia, at the confluence of the Niger with the great Benue from the east, is safely reached.

**The Sudan.** By this rocky and dangerous barrier we enter the Sudan. Instead of the

129. THE NIGER RIVER AND GUINEA COAST

primeval forest, with its enervating climate, and its unprogressive superstitious inhabitants, we have an open plateau, with a drier, healthier climate, and that possibility of free movement on which the spread of civilisation depends. The

people—Fulas, Hausas, and other tribes—though there is much diversity of blood, are civilised. They are clever traders, skilful agriculturists and craftsmen, devout Mohammedans, and possess the power of self-government. Till recently the region was divided into independent states, Sokoto being the most powerful. Much of it now forms the British colony of Northern Nigeria.

In the Sudan the palm oil tree disappears, but it is replaced by the equally useful shea butter tree. Sorghum, a kind of millet, and maize replace the yams of the forest Niger, and domesticated animals are once more numerous. The country is covered with villages, and there are also important walled cities, some with nearly 100,000 inhabitants, the centres of trade between the Guinea coast and the Mediterranean. The largest are Bida, near the Niger, and Kano, much further north, and better placed for the caravan trade across the desert. Blue Kano cloth, made from local cotton, is famous through half Africa, and can be bought at places as far apart as Alexandria, Tunis, and Lagos. Kano is also the great market for kola nuts. These are so valued in the Sudan for their feeding and stimulating properties that in times of drought a slave is often given in exchange for a single nut. The fruit resembles a large chestnut, and grows in long pods containing several nuts. Yakoba is the chief centre in the east. The seat of government in Northern Nigeria is Zungeru on the Kaduna river.

**The Resources of Nigeria.** Very little of Northern Nigeria lies in the densely forested coastal plain which forms Southern Nigeria. There are valuable forests in the south, producing mahogany, ebony, oil palms, kola nuts, and rubber. Agriculture is important everywhere in the plateau region. Around the rivers are rich, alluvial lands, over which the water spreads when swollen by the summer rains, and over which it deposits a mud hardly less fertile than that of the Nile. Fine crops of rice, tobacco and cotton are grown on these alluvial lands. Cotton is a native of the Sudan, and will probably become as important as in Egypt. Wheat may also become a valuable product. Towards the north, on the margin of the desert, a different vegetation appears, among which gum-bearing acacias may be noted.

**The West African Powers.** The predominant power in West Africa is France, whose sway extends from the Mediterranean across the desert and the French Sudan to the shores of the Gulf of Guinea. Along the coast, between the mouth of the Gambia in the west and that of the Niger in the east, other powers have established colonies. The narrow Gambia valley forms the British colony of Gambia. A little further south is Portuguese Guinea, separated by some 200 miles of French territory from the British colony of Sierra Leone, beyond which is the republic of Liberia. The French Ivory Coast, the British colonies of Gold Coast and Ashanti, the German Togo, and the French Dahomey, bring us to Southern Nigeria, a British possession in the basin of the lower Niger.

**The West African Coast.** Between the Gambia and the Niger mouths one may steam for days along the coast without any change in the scenery. "Imagine a sunlit sea, running in mile-long undulations, which pile themselves up on end and smite the yellow beach with a thundering crash. Beyond the beach a row of mud huts nestles beneath the shade of an immense palm, whose green fronds form a feathery lacework over them. Beyond these are cottonwood forests, while a steamy haze hangs over the whole." Only one or two settlements need be mentioned. The first is Freetown, the capital of Sierra Leone, the second town of West Africa. With its white houses set in orange gardens along the slopes of Tower Hill, and the forested heights of the Sierra Leone, or Lion Mountains, behind, it is a beautiful sight from the sea. Like all this coast it has an evil reputation for its climate, which is hot, damp, and unhealthy. Fifteen hundred miles farther east is its rival Lagos, the most important town in West Africa, "Glancing shorewards you see the inevitable line of yellow beach, but no forest behind. On a low island in a wide lagoon stands what is really a handsome town, and not the conglomeration of galvanised sheds and mud huts which form so many West African settlements." Not only is the trade of Lagos very important, but it commands the shortest routes to the most fertile parts of the Niger basin, now included in Northern Nigeria, which are inhabited by black Mohammedan races, highly skilled in many arts. A railway is being built to the Niger from Lagos.

**The Niger in French Territory.** Nearly all the rest of the Niger basin is French. The river makes a great bend to the north, separating the desert from the savana lands to the south. The most important town is Timbuktu, a few miles north of the river, but connected with it by a winding channel. Timbuktu is the terminal point of two important routes across the desert, and the centre at which the products of two very unlike regions are exchanged.

The Niger rises among forested mountains some 5,000 ft. high at no very great distance from the Senegal and Gambia. At its source it is less than 150 miles from the sea, but owing to the configuration of the country, it flows inland in a north-easterly direction for several hundred miles before it finally turns south to the Gulf of Guinea. It is the third in length, and the second in volume among the rivers of Africa. Between the Niger, the Nile and the Congo is the Lake Chad basin of inland drainage which receives the Shari river. The lake varies in size from 6,000 to 30,000 square miles according to season.

In the French Sudan the same general characteristics are found. South of the desert is a poor steppe, passing gradually into fertile savana lands, which extend to the southern margin of the plateau. The coastal lowlands belong to the forest region.

# POLISHING LEATHER

Levantiing, Enamelling, Dyeing, Staining, and Finishing  
Leathers. Grain Printing. Morocco and Chrome Finishing

Group 20  
LEATHER

5

Continued from  
page 3421

By W. S. MURPHY

**POLISHING** leather seems an easy task to the shoeblack; but that is because somebody else has made the leather capable of receiving the polish first. A very good polisher is that old machine [22] with the smooth stone worked up and down on the sloping board. The hide is fixed on the board sloping beneath the arm holding the polishing stone. Driven by a crank at what we may describe as the elbow, the arm moves the stone up and down on the leather, smoothing and polishing it finely. For giving a glaze to leather in its natural colour, brass rollers heated within are used, and the result is a hard, enamel-like polish.

**Levantiing.** Levantiing is one of the oldest and most effective methods of finishing leather. First the hide is blacked with a mixture of ox-blood and logwood brushed over it and left to dry. The levantiing machine is a spindle with four spokes, on the ends of which are glass rollers. The spindle is set to the centre of a semicircular box, the inner circumference of which is barely the thickness of the hide, larger than the circle described by the spokes. When the leather is laid in and the machine set going, the glass rollers touch lightly yet firmly the surface of the hide, and gradually impart a polish bright and indelible.

**Enamelling.** The so-called *patent* leather is used chiefly for harness; but it has sometimes been favoured by a large section of the public for boot-fronts. For this purpose the flesh splits of various classes of hides may be used. Stretching the leathers on a board and nailing them firmly down, you apply a coating of enamel and dry in a stove. When dry, put on another coat, and repeat till the thin liquid has formed a skin. A rub up on the patented side and a wipe of oil on the inner side finishes enamelled leather.

**Dyeing and Staining.** The colouring of leather is a subject of serious complexity, involving study of chemical processes far beyond our province. Even chemists of the highest repute are unable to explain clearly the principles of leather-dyeing. Fortunately, by practical

experiment, we have been able to dye leather in a way fairly satisfactory to the ordinary eye. In reality, so far as the actual work is concerned, leather-dyeing is very simple.

First, the condition of the leather should be carefully observed, and all hides of weak grain or broken hyaline rejected. If the glassy layer or the grain be injured, the dye will show up the defect. Another precaution is necessary. Goods of different tannages should never be dyed together. If the goods have been dried some time, they require to be washed and softened in the drum, in water heated to about 109° F. Freshly tanned skins are practically ready for the dye bath.

**Hand Dyeing.** Leather dyers use vessels of all sorts, from the humble earthenware crock for treating small skins to the large tank. A very good bath for hand dyeing is the *dye tray*, a shallow vat 5 ft. long by 3 ft. broad and 10 in.

deep. Having filled the vat with the proper colour, the dyer lays in the skins, one at a time, up to the number of a dozen. When the dyo has been given sufficient time to work, the skins are lifted out and put back again, the bottom one being placed on the top and the top one at the bottom. Thus the order of laying is constantly changed for about an hour, when the skins

should have been dyed. If it be desired to colour only the grain side, the skins are laid in pairs, flesh side to flesh side, and tadded in two the long way of the hide. Simple as the precaution may seem, it is entirely effective, as the dye never goes further into the flesh side than about  $\frac{1}{4}$  in. round the edges.

Hand dyeing is now practised only in small establishments or on goods requiring careful treatment. For ordinary commercial leather, mechanical dyeing baths are used, chiefly of the paddle or drumming models. The paddle bath is, of course, open, and for fine shading of colours is to be preferred to the closed drum. In most other respects, however, the drum is the better. The colour penetrates more quickly, and the temperature of the dye remains constant for a longer time.

21. POLISHING MACHINE  
(Joseph Hall & Sons, Leeds)

## LEATHER

**Staining.** Dyeing takes time, special apparatus, and a large stock of materials. For the cheaper kinds of commercial leathers, all these mean needless delay and expense. The colours chosen for staining must have a distinct affinity for leather, or they are worse than useless. With this limitation, the choice is not small. Manufacturers supply both acid and basic colours, of many shades of brown, red, green, blue, and orange, guaranteed suitable for staining. The leather having been smoothed and lightly boarded, the stain is applied with a brush. One coat is not sufficient, except in the case of heavy blacks. The first coat is allowed to dry, and a second, third, or fourth applied. As the stain is, or should be, very smooth, the more coats laid on, the smoother will be the finish of the leather.

**Dyeing Chrome Leathers.** In vegetable tannages a mordant that fixes the dyes is self-created; but for chrome-tanned goods an applied mordant is almost essential. Having been tanned and boraxed in the usual way, the hides are put in a drum containing a tanning solution, toned with gambier and fustic extract, and drummed through the liquor. The leather is partially dried by sleeking or pressing, and then drummed through an emulsion of fat and water. Some tanners prefer to dye before fat-liquoring; but circumstances may determine the order of the processes, and the difference is very slight, the chief effect being the partial solution of some dyes in the liquor.

**Finishing Leathers.** The glazing of leather grades from the soft oily polish of kid to the bright sheen of morocco and the hard glassy surface of the enamelled goods. The simplest glaze is oil. Applied with a brush, and polished up with a flannel, it gives a sweet surface to the fine leather, and acts as a preservative. For a higher glaze, and specially as a protective to weak dyes, a soap jelly is used. Caustic soda, stearic acid and water, boiled and diluted while hot with added water, make a good jelly for the purpose. It is brushed thinly over the surface of the leather, dried thoroughly, and polished up on the glassing machine. Still higher, and giving a harder finish, is a solution of shellac diluted 5 parts to 100 of water and 1 part of borax. This is applied in the same manner as the soap jelly, and results in a hard polish.

**Morocco and Fine Coloured Leathers.** The finishing of these leathers is a long and complex process, seldom practised in this country, where time and materials are so expensive. The Moors of Taflet, Fez, and Morocco still hold the bulk of their ancient trade in leather. It is nonsense, however, to say, as some do, that we are unable to produce good morocco leather. It is done every day. The softness and fine grain of morocco are produced by elaborate staking, boarding, and working with the hand, until the fibres have been reduced to complete pliability. For giving the gloss so much admired, and so indestructible, it is necessary to coat the leather with a seasoning of water, milk, and blood or albumen. When the

coating is nearly dry, but yet soft, it should be hand-glassed, or it may even be glazed under the glazing rollers in the polishing machine [21].

### Chrome Finishing.

In common with all new inventions, chrome tanning had to encounter a good deal of prejudice, and one defect seized upon was the intractability of chrome-tanned goods to fine finishing. The objection no longer holds. By the following process the manufacturer can give chrome-tanned leathers as fine a finish as can be desired. After dyeing, wash the goods in tepid water, with salt added, to the amount of three pounds for every dozen skins. Dried and cleared of moisture on the striker, the skins are nailed out flat on boards, flesh side down, and sponged over with a mixture of glycerine and

22. POLISHING LEATHER  
(From a photo in Elswick Leather Works)

water. Then lightly oil the grain side with sperm oil, and carry to the drying-room. Having dried thoroughly, the skins are taken off the boards and laid between layers of damp sawdust till the hard, dry stiffness has gone from them. Worked on the staker till smooth and flexible, the skins are given a coat of linseed oil mucilage and dried out. We are now prepared for glazing. The glaze seasoning consists of egg albumen soaked in water, with milk added. Having been carefully seasoned with the mixture, the skins are rapidly dried out in the warm stove, and glassed on the machine. This process is repeated twice over, each time with a weaker solution of the glazing mixture, and then the skins are lightly boarded against the grain, to give a surface. After being rubbed over with a soft flannel cloth damp with linseed oil, the goods are ready for the buyer.

# MAKING A SHAFT

The Tools and Processes in Excavating, Supporting, and Draining Mine Shafts. Emergency Devices. Shaft Sinking by Freezing

Group 14

MINING

8

Continued from page 8310

By D. A. LOUIS

**THE** bucket, *hoppit*, or *kibble*, employed for raising rock, etc., is sometimes barrel-shaped, and hung from three chains or a bow. Its most usual form [81] is circular with straight sides, larger in diameter at the top than at the bottom, and hung from a bow pivoted on trunnions set below the centre of gravity, so that it is top-heavy when full and will tip over of itself; but to prevent this happening during the ascent in the shaft, one or two vertical pins are riveted at the top of the kibble, and an ordinary link of a chain sliding on one or each arm of the bow passes over these pins, and so prevents the kibble from tilting. Two kibbles at least are required, one filling at the bottom while the other is going to surface, and even a third is often introduced in deep shafts in order to save time by having one filling while the others are travelling.

**Excavating the Shaft.** The excavation is conducted by drilling at the centre a group of four or five holes, called *sumpers*; they are inclined inwards, are 5 ft. or 6 ft. deep, about 2 in. in diameter for dynamite, and 3 in. for gunpowder, and may be drilled by jumpers, or by hand or machine drills, the last named for preference in very hard ground. The sumpers are charged, tamped, and fired either by electricity or fuse, the whole lot of holes being fired at the same time.

When fuses are used, different lengths are employed for each shot, so that they are fired in succession, can be counted, and any *miss-fire* detected. Before firing or after lighting the candles at the fuse, the men are drawn to the surface and the bridge run over the top of the shaft or the cover shut. The practice of excavating described above is somewhat similar to making a raise as shown in 82, but the operations are conducted downwards.

The first lot of holes form a great hole, or a *sink* or *sump*, and around it another lot of inclined holes are drilled and fired to blow away the walls of the sump and to loosen the ground for the next and last ring of holes, which are drilled perpendicularly.

The broken stuff is loaded into the kibble, which is wound up, and on reaching the surface is raised a little above the shaft to allow the doors to be shut or the rolling bridge with a tip waggon to be pushed over the shaft. The kibble is then lowered over the waggon, the chain links on the arms are raised off the pegs or pin, the kibble at once tips over, and the contents are discharged. The

kibble is turned up again, any loose stuff removed from the outside, the chain links readjusted over the pin or pegs, the rolling bridge run off or the doors opened, and the kibble sent down the shaft again. At the bottom the empty kibble is detached from the spring hook, the loaded one hung on, and so the winding goes on.

**Supports** As the sinking proceeds, the sides of the shaft must be supported, as in the case of the vein mining shaft, but for these large shafts, iron rings kept in place by hangers with planks at the back wedged against the rock are used [83]. The rings are made of flat iron bars from 3 in. to 4 in. wide and  $\frac{1}{4}$  in. thick. The bars are in segments with several bolt holes, and are bolted together to form the ring. The hangers are inch-square iron; the planks, 6 in. or 7 in. wide by 1 $\frac{1}{2}$  in. thick. Sometimes the temporary lining is built wholly of timber. Wooden segments bolted together form a ring or curb round the shaft, behind which backing deals or wooden lagging is driven, while stronger planks or stringing deals are nailed round it inside the shaft from one curb to another to hold them together, and small props (*punch props*) are placed between them to keep them in position, like the studdles in vein mining.

**Bricking the Shaft.** When a sufficient depth has been sunk, bricking is started, and for this purpose a part of the shaft (which all the way down has been made sufficiently large to allow for the bricking) is reduced to its finished size, leaving a ledge all round which is known as the *curb-bed*. This is most carefully levelled, and its centre made to coincide with the centre of the shaft, the spirit level and a centre line being used for the purpose. An oak or cast-iron curb (the latter is better) is laid on the bed and wedged tightly from behind with hard wooden wedges, while it is kept perfectly level and properly centred. The brickwork is then started on this wedging curb. Ordinary bricks are used, and it is good practice to make the walling thicker at the curb than in the rest of the lining. The walling is kept vertical by means of plumb lines hung from curb to curb, and is continued up to the surface or to a previous section of walling. When starting sinking below a curb, the shaft is very gradually increased to the ordinary size; in this way a bracket is left all round to support the brickwork above. The walling is done in convenient sections, and when a lower section

81. TILTING KIBBLE

reaches an upper section, the supporting bracket of rock is removed in short lengths, and the brickwork carried right up to the curb.

**Scaffolding for Shaft Sinking.** The style of scaffolding used in ordinary bricklaying work requires shifting each time the work rises beyond the reach of the men, and this is too troublesome and laborious in a shaft; therefore suspended scaffolds that can be raised or lowered by the capstan engine at the surface are used. A good form of scaffold consists of three parts—a central one and two side pieces—working on hinges, connection being made to two ropes from the engine by two sets of three bridle chains. At a signal it can be raised or lowered, and is fixed at the required position either by bolts driven into holes in the shaft sides or by wedging. When not in use it can remain suspended in the shaft, and even act as a protection to the sinkers, the central piece being then removed to allow the passage of the kibble, or else it can be folded up on its hinges and put on one side.

**Sinking Troubles.** Unless some troubles arise, the sinking continues in this way until the desired depth is attained. But troubles are almost sure to arise, the most common being the presence of water. Water-bearing beds are almost certain to be encountered in the upper formations—above the coal measures for instance—and two matters have to engage the attention of the miner, namely, keeping the water down in the shaft so as to enable the sinking operations to proceed, and, secondly, making provisions for preventing the water interrupting future operations in the shafts.

**Removing Water from the Shaft.** If the quantity be small, it is done by winding in the ordinary kibble, or in a special water-barrel. To prevent the water splashing about in the shaft during mining, arrangements are made to collect it at the position of the spring; holes are left in the brickwork, and

pipes are provided for the water to run down, while the next curb is modified somewhat, being provided with a gutter going completely round the shaft, and known as a *water-ring* or *garland*. The water is drained from the garland by a pipe, and as the shaft deepens is conducted from one garland to another, and ultimately to a tank or to a water-barrel at the bottom of the shaft, which is wound to surface when full. There are various forms of water buckets; some are provided with a valve opening upwards in the bottom, which prevents the water flowing out until the barrel reaches

the place where the water is to be discharged, when the valve is opened automatically or by some simple means. When, however, much water is encountered, more serious means have to be adopted to keep down the water. The pumping engines at the surface may be called into requisition, and suspended lifts or special sinking pumps may be used; sometimes all are required, as happened in sinking the shaft at Dover.

### Tubbing, or Keeping Back Water.

This is done by providing an impervious lining to the shaft; wood, brick, or cast iron may be used. A watertight lining of wood or brick is known as *coffering*, while the cast-iron lining is known as *tubbing*. Wood is not a satisfactory material for the purpose, as it is seldom really watertight and requires constant attention. When brick is used, concentric rings of brickwork with intervening spaces filled with cement are built up and form the coffering, while the surface at the back of the brickwork is filled in with soil. Coffering is cheaper than tubbing, but cannot withstand great pressures; so that usually when the depth exceeds 100 ft. cast-iron tubbing is used, either in the form of continuous rings or more frequently in the more convenient form of plates or segments, generally about 4 ft. long and two or three in depth, and varying in thickness to suit the pressure to be resisted. They are cast with flanges, cross-ribs and brackets at the back to strengthen them, and with a projecting lip along the top and one side to provide a surface to wedge against and to keep the sheeting and adjoining segments in position. There is also a hole in the centre of each segment for the escape of water during the erecting of the tubbing.

When tubbing is employed, the sinking is continued through the water-bearing strata until some impervious formation is met with, then good ground is carefully selected and a bed is formed upon

which to place the wedging curb. This bed is dressed with great care with chisel and hammer, no blasting being permissible; it is tested with the centre line, straightedge and spirit-level, and only when quite true is a layer of soft wood or tarred flannel laid upon it, and upon this the *wedging curb*. This is built up in segments, which may be 18 in. wide, 6 in. deep, and are cast hollow to reduce weight. They are set in position with the open side towards the side of the shaft, and half an inch sheeting of soft deal is placed in the joints with the end of the grain turned towards the inner part of the shaft. The

32. ROCK DRILLS IN RAISE

space behind the curb is then packed tightly with dry wood free from knots and with the grain upwards. Hard, dry wooden wedges are then driven into the packing, taking great care to do it all round equally so as not to displace any segment of the curb.

**Laying the Tubbing.** Each plate or segment is let down by the winding rope, hung from a large D link, the pin of which passes through the hole in the plate. This is easily swung into position by the workman; the plates are laid side by side on the curb, fir

sheeting being placed between the curb and the plate, and also between the segments when the ring is complete. Wedges are driven down between the back of the segments and the walls of the shaft to prevent any of the segments moving. When the wedging is complete, a layer of sheeting is laid on the top flange of the ring and a second row of plates put in position with sheeting between and breaking joints with the plates of the ring below—that is, the joints between the segments in one ring come into line with the centres of the segments of the ring above and below. The tubbing is carried on in this manner as far as is desired, terminating with an upper curb having a ledge beneath it to hold

the top ring of tubbing in position and to aid in making a watertight joint. The lower part of the space between the shaft wall and the ring of tubbing is filled up with concrete, the upper part with soil, clay, or ashes. When a column of tubbing is completed, all the horizontal and vertical joints are carefully wedged, as long as an opening can be made in the sheeting with a chisel. This wedging is started from the lowest ring, and as each plate is wedged the centre hole is plugged up. If all the operations have been properly conducted, the length tubbed, instead of being drenching wet, will be quite dry.

**Shaft-sinking in Loose and Water-bearing Ground.** Shaft sinking has frequently to be done in ground of a loose, wet character, such as running sand or water-

bearing gravels. If the troublesome ground be not very deep, piling is adopted—that is, wooden planks are driven downwards all round the shaft, with their edges together, and are supported on the inner side by curbs. The planks are generally 10 ft. to 18 ft. long, 6 in. wide and 3 in. thick; the lower ends are tapered off to a cutting edge, the upper ones being protected by hoop iron. When the ring is complete and down to 6 ft. the ground is removed from the inside, another curb is put in, and the driving continued. After 12 ft. or so has been

removed, arrangements are made to start a fresh ring of piling. For this purpose a second curb is laid within the lowest curb of the preceding ring, leaving a space of 3 in. between the two curbs, and the piling is continued in the same manner until the whole loose ground is passed through and the stonehead reached. It will be noticed that the shaft is reduced in size by each ring of piling to the extent of twice the thickness of the boards and the curbs, and this has to be taken into consideration when arranging the size of the first circle, so as to allow for a full-size shaft after the last ring of piling.

**Sinking by Drums.** Piling is a very expensive operation, so that when the loose ground extends for

a considerable distance down, some alternative method is adopted. In one of these, a drum or cylinder of sufficient diameter to allow the walling of the shaft to be subsequently erected inside is built up at the surface and gradually forced down through the loose ground and into the solid rock below. The drum may be constructed of wood, iron, steel or brickwork, and in every case the procedure is the same. Several rings are built up and then the drum, which in all cases is provided with a cutting edge round the lowest ring, is forced down by weights, or by screw or hydraulic pressure, care being taken that it goes down truly vertical, for which purpose guide frames are erected. When it has sunk a convenient depth the sand or soil is excavated from the interior, and these operations

83. TEMPORARY LINING IN A SHAFT

are continued until the solid ground is entered ; then the permanent wading can be put in.

But even greater difficulties than these already mentioned are sometimes encountered while sinking shafts for coal mining ; for instance, loose water-bearing strata of such magnitude as to defy ordinary tubbing operations may be encountered, and then either the mobility of the water must be overcome in some way or the sinking and lining operations must be conducted in the presence of the water.

**Shaft-sinking by Freezing Methods.** The mobility of the water has been overcome by the ingenious method of Poetsch, which has been modified by Gobert.

By these methods the heroic conception of rendering the whole mass of water-bearing loose ground around and about the shaft solid by freezing the water into ice has been put into practice, and has proved highly successful in several instances. The mass is frozen solid, and then sinking is conducted much in the usual way. Strangely enough, those portions of the broken stuff brought to surface which consists of particles of sand and earth cemented together by ice, have very much the appearance of marble. The freezing is effected by sinking a ring of boreholes around the area of the shaft and right through the loose water-bearing strata and well into the solid rock below, and into these boreholes tubes are inserted. The tubes serve for circulating brine in the Poetsch process and liquefied ammonia in the Gobert process within the boreholes. In both cases the cooling materials are caused to circulate by means of pumping machinery.

**The Gobert Process.** In the case of the ammonia, which, as may be gathered from the chemistry course, is a gas, this gas is converted

into a liquid by application of pressure and cold ; it passes into an inner tube in each borehole, and from perforations in this tube exudes into the surrounding space enclosed by an outer tube ; the pressure is thus relieved, and the liquid changes at once into gas, absorbing an immense amount of heat in the transformation. This heat is withdrawn from the surrounding areas, which in these cases is watery, loose ground. This

consequently becomes colder and colder, and ultimately solidifies around the boreholes ; the solid crust continues to increase in thickness until the solid areas around the boreholes meet together, and

form a complete wall of material frozen solid extending from the top to the bottom of the boreholes. Then only is the sinking proceeded with. The gaseous ammonia is pumped from the tubes continuously, and is again passed through the condensing machinery, hence it performs a complete cycle and the operation is continuous.

**The Poetsch Process.** In the Poetsch process, instead of using a gas, a liquid that will not freeze is employed—brine, for instance. This is cooled by cold-producing appliances,

passes underground and down an inner tube in each borehole, and exudes into an outer tube, from which it is pumped up again to the cooling plant at the surface, having in its course taken up heat from the area surrounding the boreholes in the same way and with the same effect as in the case of the Gobert process. The particular advantage of the Gobert over the Poetsch is, that in the former a reduced pressure is maintained in the holes, and any leakage would not affect the surrounding mass ; whereas in the latter a high pressure is maintained, and any leakage allows brine to escape, which would either thaw the area around the leak or else prevent its freezing.

**Shaft-sinking in Water.** A description of the sinking operations at Dover will furnish an example of another method of overcoming the difficulties connected with water-bearing loose ground, and will, moreover, furnish an example of boring operations on a large scale.

The Kind-Chaudron method of sinking was adopted [84 and 85]. In this case the derrick had become a *barraque*, consisting of a tower 71 ft. high and a wall 94 ft.

84.  
SHAFT-SINKING IN  
WATER BY BORING

long and 34 ft. wide, with a transept for accommodating the balance beam and hoisting engines. In the centre, at the pit top, an octagonal chamber 20 ft. by 22½ ft. by 6½ ft. deep was provided for the sinkers to work in. At a height of 45 ft. a track, *h*, of 7 ft. gauge carried the cars for supporting the trepans *a* *b* (as the compound chisels are called), the sludging barrels, *c*, and free-fall apparatus; and 20 ft. above this track there was another, *g*, of 37½ in.

gauge for cars from which the boring rods, *f*, hung suspended when not in use. At the very top, above the centre, a small chamber protected the pulleys for directing the winding ropes; they were supported on massive oak balks. All parts were accessible by ladder-ways, and there were galleries with working platforms at different levels for the necessary manipulations over the shaft. The procedure followed was to bore a hole with the small trepan, *b*, 109½ in. in diameter and 30 or 40 ft. in advance of the full-sized shaft, and truly vertical, following on with the large trepan, *a*, to the full size of the shaft, a guide plate fitting into the hole made by the small trepan maintaining the centre and verticality of the boring. The debris from the small trepan was handled in the usual way, and that from the large trepan accumulated in the advance hole, but was from time to time removed by means of the sludging barrel suspended from a flat rope and worked by the hoisting engine. The apparatus was the same as in other boring, but on a very large scale. There was the stirrup, or temper screw, and swivel and tiller; the rods of pine 8½ in. square in sections and 65 ft. long, heavily capped with iron and provided with male and female screws; there was a free-fall appliance with the small trepan, and a sliding joint for relieving shock with the larger one.

The small trepan was a massive structure of cast steel and wrought iron, weighing 12 tons and nearly 9 ft. wide, provided with eleven cutting teeth in the axis and four in each of the curved ends. The teeth were 15 in. high and 8 in. to 11 in. wide, and were set with their blades parallel to the axis of the trepan. The trepan was mounted in a framework of wrought-iron plates and oak balks 8 ft. high. The large trepan, also constructed of wrought-iron and steel, weighed 27 tons, the base being over 17 ft. long, more than 3½ ft. deep, and 11 in. thick at the centre, with twelve cutting teeth in its length and ten in its curved ends. There were no teeth at the central portion, which,

instead, was provided with guide plates to fit in the hole made by the small trepan. The framework of struts, stem-piece and side guides, all of wrought iron and oak, was 12½ ft. high and 18 ft. wide, the whole structure standing 22 ft. In both trepans the teeth were set lower at the centre than at the ends, so as to produce a cutting with sloping sides, that enabled the debris to slide down and collect at the centre. The beam

was given the reciprocating motion from a cylinder 40 in. in diameter, by a piston receiving steam on the upper surface only with a stroke of 40 in. Between each stroke a slight turn was given to the trepan by eight men in the boring chamber moving the levers of the tiller. The hole was lined with continuous rings of tubing 4 ft. high, 15 ft. in diameter, and varying in thickness from 1½ in. at the top to 4½ in. at the bottom, and in weight from 7½ tons to 17½ tons each. There were 278 rings, the total length of tubing was 1,120 ft. and its weight 3,675 tons; they were bolted together by means of the flanges provided for the purpose. A moss-box was used in this case. This is a space packed with moss, which is squeezed together

when the tubing comes to rest on its curb, and makes a watertight joint. The usual false bottom and equilibrium tube were employed. They enabled the whole mass of tubing to float, and took the weight off the suspending rods; when the weight was not sufficient for purposes of lowering, water was pumped into the tubing to neutralise the effect of the buoyancy of the water outside. All the accessory parts were removed when the tubing was once in position. Fresh rings were added at the top, and the lowering was

done by means of screws at the top of the suspending rods. These and the other parts are shown in 85. To keep the great column of tubing perfectly true, several men at each screw gave a turn at exactly the same time; the least canting would have given rise to enormous trouble. In one year the shaft was sunk—or, rather, bored—90 ft. by this means. This furnishes a very good example of the magnitude boring operations may attain, and of the magnificent expedients mining engineers adopt to render valuable minerals available if circumstances demand it.

#### The Pattsburg Process of Sinking.

This process is really a modification of the Kind-Chaudron System. The tubing, however, is forced down by hydraulic rams, and the shaft is bored in one operation by an implement resembling

85. LOWERING LINING IN SHAFT FILLED WITH WATER

the large trepan, but the cutting blades are continued right to the centre. The cutter is given a reciprocating motion, and a slight turn between each blow. But there are one or two features about this process worth special attention. First, to aid the dislodgment of the broken material, water under high pressure is forced down the hollow bore rod, and issues from holes at the bottom of the cutter blades. This not only keeps the surface at the bottom fresh and free for the cutters to work against, but also keeps the sediment in suspension, and enables it to be dealt with by the *Mammoth pump*.

This contrivance consists of a pipe about 6 in. in internal diameter extending from the apex of the cutter to the surface, and having alongside another pipe  $\frac{1}{4}$  in. in diameter, down which air at great pressure is forced. This air escapes at the bottom into the large tube, up which it ascends, and carries with it the water holding the waste material in suspension, and all sludging operations are obviated.

**Triger Process of Shaft-sinking.** Another process, which is quite old, dating back to 1839, and due to the ingenuity of Mr. Triger, consists in forcing down a cylindrical casing with cutting edge, as in the preceding method, but keeping out the water at the bottom by forcing down air. Of course, air-tight partitions have to be made across the top of the cylindrical casing, which, in fact, is a caisson and may be compared to an inverted tumbler. The pressure of the air has to be equal to that of the water, which makes the process unsuitable for great depths, unless the pressure is relieved, but it has been applied successfully to depths exceeding 100 feet.

It is a method, however, which is frequently employed in working in river beds, for putting in foundation work, and for driving tunnels. The tunnel under the Thames at Blackwall was driven by a modification of the method, and the writer had an opportunity of experiencing the inconvenience attached to working in an atmosphere having a pressure of 25 lb. to a square inch; but men have worked for short periods under double that pressure. This, however, is one factor that makes the Triger method impossible for the workmen when a great pressure of water has to be dealt with. Recently the system has been successfully applied in sinking two shafts at Ardeer, in Ayrshire, 90 ft. deep. The maximum air pressure used was 23 lb. The shafts were sunk 48 ft. apart. The caisson consisted of a steel shell  $\frac{1}{2}$  in. thick, 17 ft. 7 in. in external diameter. The inside was lined with brickwork, with concrete between the brickwork and shell. The internal diameter of the finished shaft was 14 ft.

**Regulations as to Shafts.** Whichever way the sinking is conducted, two shafts at least must be provided to ensure proper ventilation. The shaft by which the fresh air enters is known as the *downcast* shaft; the one through which the air from the mine is extracted is known as the *upcast* shaft. The shafts are usually sunk near each other, so that the surface arrangements are centralised.

**The Pit Bottom.** The pit bottom is the position where the shaft cuts the seam, and when once the shaft is down this becomes the busiest spot underground. All that comes down from the surface and all that goes to the surface has to be assembled at the pit bottom, and, in addition, water pipes, steam pipes, haulage ropes may have to be accommodated; moreover, sufficient standing room must be arranged for a large number of waggons, so that when the colliery is started the proposed output may be maintained by keeping the winding operations going without interruption. The arranging of the pit bottom, therefore, is a matter that requires serious consideration, and even though excavating underground is costly, it is advisable in a large mine to enlarge the shaft at this point so as to make on each side of it a passage along which tramways may be laid, in addition to those leading direct to the shaft; moreover, the openings made into the coal seam itself on each side of the shaft are advisably made large, and are supported by brick arches, the brickwork of the shaft being connected to the arching by belling out. Some mines have splendid vaulted stations at the pit bottom, that, with the excellent lighting, recall some mediæval baronial hall. The tramlines are arranged so that those bringing full tubs are graded towards the shaft, while those for conducting empty tubs away from the shaft incline in the opposite direction, and the side lines are also inclined so as to allow the empty tubs to run back to where they are wanted, being helped over intervening up-gradients mechanically—in fact, all these movements of the waggons take place without the application of manual labour, except where the waggons are placed in the *cage* by the *hanger on* or *onsetter*.

**Cages.** For bringing the coal to the surface cages are employed, usually two. The ropes from each are wound in the reverse direction round the drum of the winding engine, and pass over independent pulleys in the head gear; hence, as one ascends the other descends.

The *cages* consist of one or more platforms, called *decks*, supported by a steel framework; the decks are provided with rails; the number of decks and the size of the decks depend upon the size of the shaft and the quantity of work it is intended to wind. Guides, either of bars of timber or iron rails, fixed vertically, or of weighted wireropes, hung vertically in the shaft, serve to keep the cages from swinging about or from bumping one another when passing. The cages are provided with shoes that slide over the guides. The rails on the decks of the cage are of the same gauge as the tramlines on the surface and underground, so that the tubs can stand on them while the cage is travelling up or down, but can easily be pushed off or on at the end of a journey. Small waggons are used because they are convenient to handle, and because they do not require such large excavations as large ones would do. When shafts, guides, cage, and pit bottom are all in order, or even before, the extraction operations are started.

# THE HUNDRED YEARS WAR

The Battle of Agincourt. Accession of Henry VI. The Triumph of Joan of Arc. Loss of Normandy. The Jack Cade Rebellion

Group 15  
**HISTORY**

24

Continued from  
page 1251

By JUSTIN MCCARTHY

France offered to treat for a surrender of the Duchy of Aquitaine, but Henry was anxious for the acquisition of Normandy, and not of any southern region, and he landed his army on the northern coast, resolving to make an attack on Calais. His landing had just the effect that might be expected upon a people like the French. The Burgundians and the Armagnacs closed their ranks and prepared to resist the foreign invaders. Henry had only an army of about 30,000 men, but with this force he captured Harfleur as a preliminary to his march on Calais. His force was worn out and miserably provided with food, and he soon found that directly across his line of march was arrayed a well-conditioned, well-supplied French army, amounting to at least twice the numbers of his men.

**Agincourt.** Probably the conditions under which the coming battle had to be fought only served to arouse to its highest pitch the courage and resolve of the English sovereign and the English soldiers. For the English had but one choice before them—either to accomplish a complete victory or to suffer defeat and destruction. The French might prolong the contest as long as they felt inclined by delays, by military strategy, by the judicious disposal of their greatly superior numbers, and by the coming up from day to day of additional French forces; but for the English it was all or nothing. Henry resolved to rush to the battle at once; but he chose his ground well, and the first knowledge that the French had of the opening attack was conveyed to them by sudden showers of the barbed and winged weapons of Henry's archers. The archers were famous masters of their weapons, and they inflicted fearful slaughter on the yet unprepared French. But the Frenchmen were not to be easily driven from the field, and they succeeded more than once in driving some of Henry's archers back into the shelter of woods near at hand. Even this did not avail them, for the English archers still poured their shafts in upon the rallying French, while at the same moment Henry, with a large body of his best men-at-arms, made an attack on the main rank of the French.

**A Brilliant Victory.** King Henry displayed brilliant soldiership; he was once struck to the ground by a heavy blow from a mace, and had the crown on his helmet completely severed by a sword stroke. Good fortune still aided him, however, and he was able to lead his troops until they had accomplished a complete victory, memorable to all time as the battle of Agincourt. It is stated even by careful historians that 11,000 Frenchmen were left dead on the field, and that France lost more than

100 of her princes and nobles among those who had fought in vain against the all-conquering English king and his army. Henry could not follow up this great victory with a forward policy. His army was so exhausted in military resources and even in supplies of food, and so diminished in numbers that he could do nothing for the hour but return to Calais, and thence cross to England.

The two states were still at war, and each was doing its best to hold the Channel; but Henry was making preparations for a renewal of his enterprise. He raised another army, composed of some 40,000 soldiers, crossed the Channel, captured several towns and ports, made himself master of Lower Normandy, and laid siege to Rouen, then one of the greatest and most prosperous of French cities. Rouen held out for six months with indomitable courage and perseverance; but it had an enemy within its walls—more terrible even than the English soldiers—which threatened it, in the shape of famine.

**Alliance Between France and England.** Henry saw that the time had come to offer terms to his enemies in the hope of inducing them to yield to his demands without further loss to himself. He was favoured in this desire by another outbreak of hostility between the Burgundians and the Armagnacs, and by the assassination of the Duke of Burgundy—a tragic incident of faction which made the Burgundians ready to ally themselves with Henry to obtain revenge upon their enemies. The new Duke of Burgundy, Philip, offered an alliance with Henry, and proposed to make him Regent of France during the life of the mad King Charles, to give him the hand of the King's eldest daughter Catharine in marriage, and to recognise his right of succession to the crown of France.

This apparently satisfied Henry's claims for his country and his ambition for himself. A treaty was concluded by which a perpetual peace was to be established between the two nations. Normandy was to be part of the dominions of England, Henry was to be the Regent of France and to stand next in succession to the throne. He entered Paris in splendid triumph with the King, who, being entirely mad, was probably less astonished than any other spectator of the scene. The treaty was solemnly confirmed by the States-General of France in Paris. Henry's military work was now reduced to that of conquering rebel forces on behalf of the King of France nominally, and of the Burgundian party actually, and he accomplished his work with the skill and success which are for ever associated with his name. But an enemy now confronted him against which the skill of the military

conqueror cannot prevail. A heavy attack of illness came upon him, for which medicine and surgery could find no remedy, and he died at Vincennes on August 31st, 1422.

**One of the World's Great Conquerors.** Henry V. must ever be enrolled among the world's great conquerors. He had much also of the statesman's capacity, and even in his most daring enterprises his mind was closely engaged in studying the surrounding possibilities and the consequences most likely to follow from each stroke of policy. He was in his maturer years a man of exalted personal character, religious, and even devout, and a true friend to his friends. He was often severe and pitiless to his enemies, but in those days the quality of mercy was regarded as something to be used entirely at the discretion of the conqueror. Judging the man and his career as a whole, Henry V. forms one of the noblest figures in the history of his country.

Henry VI., the only son of his dead father and of Catharine of France, was but a child when he came to the throne, and during his long minority his uncle, Humphrey Duke of Gloucester, was appointed to be Protector of the country, with a council formed by Parliament for the purpose of advising and assisting him. If Henry VI. had been a full-grown man, and a man with a positive genius for the government of a state, he would have found it no easy task to manage the affairs of England during the trying time which saw him called to power. The great foreign wars which had been carried on had left the country heavily embarrassed. The struggles between the rival baronial parties were causing England to resemble a land torn up by civil war. Vehement efforts were still made to suppress the Lollard movement, which contrived to hold its way, despite all opposing power.

Something like a reaction set in against the enlightened constitutional developments of recent reigns, and those who had charge of the state during the boy King's minority were agreed, if on nothing else, on the desirability of making the House of Commons as nearly powerless as possible, and of preventing the vast majority of Englishmen from having any share in the election of its members.

**Joan of Arc.** The war in France was still going on. Charles VI., the brainless king, had died, and the Dauphin had assumed the title of Charles VII., but his army had met with an almost destructive defeat by the English in 1424. Then there arose on the scene of the great struggle between England and France one noble, heroic, saintlike figure, the like of which has not appeared in the world's history. The destiny of France underwent a sudden change by the genius, the devotion, the inspiration, of the Maid of Orleans, Joan of Arc. This girl was the child of poor, hard working parents in the village of Domremy, in Lorraine, and was born in January, 1412. She had spent most of her early girlhood in the woods near her home, and had been from her earliest years filled at once with a strong religious faith, with a love for her country, and a sympathy with its sufferings.

The struggle between England and France began to make its existence felt even at Domremy. The Duke of Bedford, who had taken the command of the English forces in France on the death of his brother, was, in the opinion of many well-qualified historians, hardly inferior to his dead brother in military genius and statesmanship. France seemed to have reached a profound crisis. The Duke of Bedford had strengthened his alliance with the Dukes of Burgundy and Brittany, and he held Northern France completely in his power. The war had spread so far towards the home of Joan and her parents that more than once they had been compelled to fly into the woods for safety from some of the marauding bands which hang upon the skirts of moving armies.

**A Girl at the Helm.** Utter misery prevailed in the country, and some of the towns, suffering from famine, felt compelled to close their gates against the agricultural labourers who rushed to them in the hope of finding shelter and food. During all this time of sore trouble Joan had devoted herself to the care of the suffering, and her mind was filled with a sense of the misery coming over France, and a yearning for some interposition from the powers above to rescue her native land from its accumulating calamities. Suddenly there came into her mind the memory of some old prophecies, which foretold that when France should be in extremest danger she was to be rescued by a young maid from the Lorraine region. She became convinced that she was the girl to whom, by the will of Heaven, this great task was to be assigned. She persisted in saying that she must go and see the Dauphin and tell him that she had a mission from Heaven to save France, and that he must put her in command of an army to accomplish the celestial purpose. She saw the Dauphin at Chinon, succeeded in convincing him of her sincerity, and he even seemed to believe that in the terrible pass to which the fortunes of his country had come there might well be warrant for the hope that Providence would intervene for the defence. Joan was authorised to lead a body of 6,000 men to the relief of the city of Orleans, then besieged by an English army. The men-at-arms who followed increased in numbers as they continued their march, and before she reached Orleans she had some 10,000 soldiers with her. She at once ordered an attack upon the besiegers, who were occupying some forts around the city.

**Joan and the Dauphin.** There was now a strong force to assail the English, made up of those who had been defending Orleans from within and of Joan's enthusiastic followers, and the English were unquestionably outnumbered. Despite the sudden surprise put upon them, the English fought with splendid courage and determination. Joan was wounded outside one of the forts, but she continued to urge the attack on the fort, and proclaimed that as soon as her standard should touch the wall her men would enter the fort. Her prediction proved true, and the assailants carried the fort. The siege was abandoned the next day, the English forces after their hard fight withdrawing in good order.

Joan resolved to lead her army at once to Rheims, where the coronation of the King was to take place. She had some trouble in prevailing on the weak-spirited Dauphin to hasten onward to his coronation, but her enthusiasm seemed capable of inspiring even the weakest nature, and her army increased greatly in numbers as it advanced upon the gates of Rheims. Within that city the coronation took place, and Joan believed that her mission was accomplished.

**Joan Burned at the Stake.** There were more battles, in which Joan behaved with all her wonted bravery. She was much disappointed by the failure of the King's forces to recover Paris, and, feeling that she must do something to make an impression on the enemy, she led as many soldiers as she could gather to the relief of Compiègne, then besieged by the Burgundians, and there, while heading a gallant attack, she was captured and handed over, a prisoner, to the Duke of Burgundy, and was sold to her greatest enemies, the English. The English, who had always regarded the victories won by Joan as the triumphs of diabolical sorcery (a belief quite in accordance with the superstition of the times), sent her to prison. After a year's incarceration, she was put on trial on a charge of heresy and witchcraft. Joan bore herself throughout the trial with her characteristic courage and devotion. She was tried at Rouen, and eventually condemned as a sorceress, and was doomed to death. In the market place of that town a pile was raised. Joan was tied to the stake, a fire was lighted, and the girl was burned to death. This was on May 30th, 1431. From the days of her brief career the mastery of England over France was practically at an end. There were struggles to retain Normandy, there was an English Court established for a short time at Rouen, but after a while France became mistress of herself and was free from foreign dominion.

**The Loss of Normandy.** Soon after the epoch of Joan of Arc, that which was called the Hundred Years War may be said to have come to an end. England still made efforts to retain some power in France, and for a time the efforts of the English leaders were concentrated on still upholding the claim on the sovereignty of Normandy. The Court of King Henry was actually held for a year at Rouen, and a system of orderly and satisfactory government appears to have been established there. But it was already becoming evident that the claim of an English king to rulership over any part of France could not be much longer maintained; Paris was recovered by the Dauphin of France in 1436, and four years after Normandy had to be given up, and the result of the Hundred Years War was the expulsion of the English as rulers from every part of France. England had not, indeed, suffered much substantial loss of territorial power and dominion, for her rulership over any part of France had been at its highest point more nominal than real. France came out of the long struggle what she had never been before in the days of civilisation—a consolidated, united, and powerful monarchy.

**The Revolt of Jack Cade.** The recent disasters in France had aroused in England a fury of indignation against the system of rule which had brought about such an unnecessary waste of treasure and life. There was a great revolt in Kent in 1450, chiefly made up of the industrial, farming, and trading classes, but joined by many belonging to the higher order. This movement was led by a man named Jack Cade, a name still remembered in English history.

Cade had in his early days escaped from Kent, where he was accused of having murdered a woman, and had fled into France, where he took service against the English. He returned to England, assumed the name of Mortimer, set up in Kent as a physician, made for himself a reputation, and married the daughter of a local squire. He became a man of importance in the county, and as the discontent arising in that region, and through many parts of England after the failure in France, was strong among all classes he became the leader of the insurrectionary movement in southern England.

He proclaimed himself captain of Kent, marched on London with an army some 20,000 strong, and encamped on Blackheath. There he and his leading associates drew up what they called "The Complaint of the Commons of Kent," and marched into London. The purpose of the Complaint was to demand a change of Ministry, a series of economical and administrative reforms, the restoration of electoral freedom, which had been greatly broken in upon in recent years, and a number of other changes in the system of government, demands which seem now to be entirely justifiable and reasonable.

**Invasion of London.** The council set up to represent the Royal authority refused to entertain the Complaint, and thereupon Jack Cade and his army obtained a complete victory over the Royal forces at Blackheath, and actually marched into London, which they occupied for two days. The Kentish invaders were harsh and stern in some of their demands, and they compelled the Lord Mayor of London to condemn Lord Say, one of the most detested among the King's Ministers, who was executed under their coercion. The Council of Ministers felt that the trouble was now becoming serious. The Royal Council, however, decided upon the policy of conciliation rather than of retaliation. They promised to receive and consider the Complaint, and offered pardons to all who had taken part in the rising who were now willing to go back to their ordinary occupations. Cade did his best to keep his followers with him, but they soon began to disperse, and the citizens of London made up an army of their own to occupy London Bridge against the invaders. Cade, failing in his effort to keep his men together, tried to escape, but was pursued into Sussex, and killed on July 12, by Alexander Iden. The Royal Council did not punish Jack Cade's rising; no further notice of the Complaint was taken, and the Duke of Somerset remained the leading member of the Council.

# FARMING IN NEW ZEALAND

Agriculture in New Zealand and Tasmania. Sheep Farming, Dairying, and Land Tenure. Fruit-growing. The Best Books on Farming

By Professor JAMES LONG

## NEW ZEALAND

Although the splendid Colony of New Zealand consists of three main islands, known as the North, Middle, and Stewart Islands, there are a number of smaller islets which now form part of the country. For our purpose, the North and Middle Islands need only be referred to.

**A Pastoral Country.** New Zealand proper is furnished with magnificent mountains, which cover about one-tenth of its surface in the north. There are, however, large plains which are not only fertile but well furnished with herbage, and where the land has been cleared sufficiently for the sowing of grasses (chiefly those known in Great Britain), as it has been to the extent of 12,000,000 acres. The pasturage is of a high order and splendidly adapted to the production of beef, mutton, and milk. New Zealand is, in a word, chiefly pastoral, and it is for this reason that the mutton, wool, and milk industries have flourished.

In the North Island there are great openings for agriculture proper owing to the suitability of the plains and valleys. The level portion of this island includes some 13,000,000 acres of land, a large portion of which is forest and swamp, which, when cleared and drained, will be fit for the growth of agricultural crops. The bush land is being systematically reduced by settlers, who cut the trees, burn the bush, sow grass seed, and create most excellent pastures. In spite of the mountainous character of a large portion of the Middle Island, a considerable area is well adapted for grazing, while the valleys, in which the soil is so suitable, are certain to be ultimately converted by the plough into fields of grain and other agricultural crops. In the Canterbury district alone there is a large area of flat country extending 160 miles to the south-west, while in Otago there are fine plains and fertile valleys suitable for the purposes of the farmer. In the Middle Island the land available to the agriculturist reaches some 15,000,000 acres, of which 13,000,000 are better adapted to grazing than to tillage, after clearing and being sown with grass seeds, for the preparation of which the plough or any other implement of the kind is seldom necessary.

**Climate.** As regards climate, little need be said. The country is known to be mild, salubrious, and healthy. In 1904 the range of shade temperature in Auckland varied from 61° F., which was the lowest maximum in July, and 79° 5° F., the highest maximum in February. The minimum temperature gave the lowest reading as 37° F. in July and August and 53° F. in February. In Wellington the mean temperature, extending

over four years, was 33° F. as a minimum and 78° F. maximum. Again, taking the average of four years, we find that at Brisbane the highest average was 97° F. and the lowest 39° F., which figures may be compared with the following:

|                              | Degrees F. |         |
|------------------------------|------------|---------|
|                              | Highest.   | Lowest. |
| Sydney, New South Wales ..   | 94         | 39      |
| Melbourne, Victoria ..       | 101        | 32      |
| Adelaide, South Australia .. | 108        | 36      |
| Perth, West Australia ..     | 107        | 37      |
| Hobart, Tasmania ..          | 94         | 33      |

The estimated value of the agricultural produce of New Zealand for the year 1902-3 was £18,600,000, while in the year 1905 the area covered by wheat and other cereals, and the yield per acre in bushels were as follow:

|              | Total Yield,<br>Bushels. | Area in<br>Acres. | Average<br>Yield,<br>Bushels. |
|--------------|--------------------------|-------------------|-------------------------------|
| Wheat .. ..  | 9,123,673                | 258,015           | 35.36                         |
| Oats .. ..   | 14,553,611               | 342,189           | 42.53                         |
| Barley .. .. | 1,128,164                | 29,484            | 38.26                         |
| Maize .. ..  | 490,405                  | 10,084            | 8.63                          |
| Rye .. ..    | 31,612                   | 1,129             | 28.00                         |

**Grasses.** In October, 1904, 4,750,000 acres were sown with grass and clover after ploughing, while 7,500,000 acres had been sown without ploughing. In addition to these areas there were 17,000 acres of garden land, 27,000 acres of orchards and vines, and 52,000 acres of forest tree plantations.

Grass seeds are extensively grown in the Colony, rye grass alone covering 31,000 acres, and yielding at the rate of 24 bushels of 20 lb. each per acre. Cocksfoot grass covered 39,000 acres, and yielded 223 lb. of seed per acre. The grasses chiefly used for sowing on the land are rye grass, cocksfoot, timothy, alsike, red and white clover, and cow grass, together with a pound of rape. Although tobacco is grown in the Colony, the industry does not progress. Apart from the area of sown grasses to which we have referred, in 1905 there were 22,500,000 acres of unimproved land available for stock feeding, and chiefly consisting of tussock, or native grass.

The livestock in New Zealand in 1904 were numbered as follows:

|              |            |
|--------------|------------|
| Horses .. .. | 314,000    |
| Cattle .. .. | 1,736,000  |
| Sheep .. ..  | 18,280,000 |
| Pigs .. ..   | 255,000    |

The quantity of wool used in and exported from the Colony amounted to 146,000,000 lb., showing an increase of 35,000,000 lb. since 1891, while the number of sheepskins exported exceeded 6,000,000.

**Sheep Farming.** In the same year there were 18,493 flocks of sheep, averaging 989 sheep per flock; 199 flocks comprising from 10,000 to 20,000 head, while 104 flocks numbered more than 20,000. Of the entire number of sheep in the Colony, 9,500,000 consisted of breeding ewes.

The total consumption of sheep, together with the export, exceeded 6,000,000, of which 4,000,000 were exported in a frozen condition, these being taken at an average of 60 lb. a head. The sheep farmer possesses considerable advantages in New Zealand, owing first to the small cost of production of mutton, and next to the high percentage of natural increase. The varieties bred in the North Island are chiefly Lincolns and Romney Marsh, while in the Middle Island the Merinos are chiefly used in the mountainous districts, and the Lincolns, Leicesters and Border Leicesters, Shropshires, and South Downs on the English grass pastures.

Cattle are increasing in number, and of the total in 1904 of 1,750,000, which showed an increase over the previous year of 143,000. 550,000 were cows and heifers intended for dairy purposes, and 218,000 for breeding purposes, a distinction which is not recognised in this country. Seventy-five per cent. of New Zealand cattle are in the North Island.

**Dairying.** Towards the end of 1904 there were 284 butter and cheese factories and 444 skimming stations. The production of butter in factories is estimated at 46,250,000 lb. per annum, while 5,750,000 lb. is the estimate of production on the farms. Each milking cow is believed to furnish sufficient milk to produce 163 lb. of butter per annum, but it is believed that the producing power of the cow of the country is 200 lb. of butter or 500 lb. of cheese. The output of butter by the factories is placed at 20,000 tons, against 14,000 tons in 1902.

Of the 314,000 horses in the Colony (15,000 more than in the previous year), 98,000 were mares over two years old, while 33,000 were mares in foal or with foals, 8,000 of the total number being thoroughbreds, 14,000 ponies, and 118,000 draught horses.

Coming to swine, we find that of the 255,000 which formed the total head, 37,000 were sows over a year old and kept for breeding purposes, while 9,000 were sows under one year, and also intended for reproduction.

**Acreeage.** The lands occupied by settlers comprised 36,500,000 acres, or 35,000 acres more than in the previous year. Ten years ago there were, in all, 46,600 holdings of over one acre in extent. In 1904-5 the number had increased to 68,000, of which 19,000 were under ten acres, and 11,000 over 10 and under 50 acres. Holdings of a large size, 20,000 to 50,000 acres, numbered 177, and those over 50,000 acres 96; these 96 farms, however, covered over 9,000,000 acres, while the 177 farms covered

5,000,000 acres more. It is curious that while farms of from one acre to 100 acres formed 56 per cent. of the total number, when the area is increased to 320 acres, the percentage is, roundly speaking, 80. Dealing with the total area of 36,000,000 acres, we find that 16,250,000 acres are freehold, 3,500,000 acres leased from private persons or public bodies, 1,666,666 acres leased from natives, and nearly 15,000,000 acres held under the Crown. In the North Island the occupied holdings reach 37,000, while those in the Middle Island number only 31,000.

**Land for Settlers.** A great work has been accomplished by the Government of New Zealand in the provision of land for settlers upon terms which are within the reach of all. Laws have been passed for the administration of Crown lands, and for their sale and occupation to tenants, with great success. Among the chief features of the existing system are State Ownership and Perpetual Tenancy with fixity of tenure, which is practically equivalent to freehold possession. A lessee, for example, having made improvements, is as secure as though the property were his own. The Land Act of 1892 provides for the occupation of settlers' holdings of 640 acres of first-class land or 2,000 acres of land of the second class, although there are certain limitations. Grazing lands of the first class are also provided, but may not exceed 5,000 acres; such lands, however, as are of the second class may reach 20,000 acres. Generally speaking, land which is open for selection by settlers is offered under three forms of tenure:

1. A payment of one-fifth of the purchase money down, and the balance within 30 days, the title, however, not being given until certain improvements have been effected.

2. A lease with a purchase clause at a rental of five per cent. on the value; this covers a period of 25 years, and conveys the right to purchase at the original price at the end of ten years, or the lease may be held in perpetuity.

3. A lease in perpetuity at a rental of four per cent. of the value.

**Leases.** Crown lands may be obtained by auction after survey, as shown under clause 1 above, or by application. Where land is acquired by lease, with the option of purchase, improvements must be made by the applicant, who must reside on the property. Where land is leased in perpetuity, or for 999 years, there are also conditions as to residence and improvements, but no right to purchase at any time. Where a settler takes bush or swamp land, he must take up his residence within four years; and in open or partly open land within one year. Residence must be continuous for six years, or for ten years in the case of land taken on a perpetual lease. Residence implies the construction of a home, which must be approved.

Improvements chiefly consist in reclamation, clearing, planting, fencing, draining, road-making, well-sinking, and embankments, and the improvement of the soil and the erection of buildings on lands of which the freehold is purchased. Improvements must be effected

## AGRICULTURE

to the value of £1 per acre on first-class land, and 10s. on second-class, within seven years, whereas land held on lease with the right of purchase or in perpetuity must be improved to the extent of 10 per cent. of the value within a year from the date of the license or lease; 10 per cent. in addition must be made within two years, and within six years there must be another 10 per cent. added, so that money must be spent in this way to the extent of 30 per cent. within six years.

**Reclamation.** The law relating to bush and swamp land deals with land of three classes: 1. Heavy bush land; 2. Light bush or swamp land; 3. Scrub land. After paying his first year's rent the settler on heavy bush land is exempt from paying further rent for four years; on light bush land or swamp he is exempt for three years from both rent and rates; on scrub lands, however, exemption extends to two years from rent and rates. On the swamp lands there need be no residence for the first five years.

There is a small farm association system under another law which provides that where a community of not less than 12 persons are associated they can, with the approval of the Minister, select land up to 11,000 acres in area. There must, however, be one settler to each lot of 200 acres, although no settler can hold more than 320 acres of land, which is held under a perpetual lease.

The Government is empowered to purchase estates from time to time, which, comprising some of the best land in New Zealand, and having been in private hands and occupied only by servants, is subsequently divided into small farms, and let on perpetual leases at a 5 per cent. rental, preference being given to persons without land, and help provided by advances of money under well advised conditions.

**Three Classes of Crown Lands.** Crown lands are divided into three classes—those in towns and villages with upset prices of not less than £2 and £3 per acre, and which are sold by auction; those known as suburban lands, sold by auction at not less than £2 per acre; and rural lands, sold at not less than £1 per acre of the first class, and 5s. per acre for the second class. These lands are both sold and leased by auction or on application.

On land known as Improved Farm Settlements blocks of 10 to 200 acres are provided. The Government contracts with the settler to clear and sow with grass seed up to 100 acres at its cost, and may advance £10 to a single man and £30 to a married man to help him to build his house. In such cases the land is leased for 999 years at a rent of 4 per cent. of the unimproved value, plus the cost of clearing and sowing. The settler must reside on the land during the first ten years.

What are known as Village Settlements are sold under other regulations. They include allotments of an acre, costing no less than £3 each, and homesteads of not more than 100 acres, which are let on perpetual lease at a 4 per cent. rental on the capital value of not less than 10s. per acre.

In the case of grazing runs, to which we have already referred, the rental is not less than 2½ per cent. on the capital value per acre of not less than 5s. per acre. These runs are leased for 21 years, with rights of renewal for a further 21 years at a rent of 2½ per cent. on the then value of the land.

Runs in the pastoral country are let by auction on terms not exceeding 21 years, and, with exceptions, must not be of larger extent than will carry 4,000 head of cattle or 20,000 sheep.

**Advances to Settlers.** Advances to settlers are made on first mortgages of lands and improvements held under various systems of tenure; these mortgages are granted either on the fixed loan or instalment systems in sums of from £25 to £3,000 on freehold lands. Advances may be made on three-fifths of the value, or up to two-thirds in the case of first-class freeholds. On leaseholds loans are restricted to half of the value of the lessee's interest, but only on the instalment system. Where a loan is granted on the fixed loan system it must not exceed ten years, the interest being at the rate of 4½ per cent. if paid within 14 days after it is due. Under the instalment system the loans are repayable in 73 half-yearly payments of principal and interest combined, with interest at 4½ per cent. if paid within 14 days after they are due. The half-yearly instalments are at the rate of 3 per cent. in cases of prompt payment for every £100 advanced.

Education is free, but compulsory between the ages of 7 and 14 years, elementary science being included in the curriculum. There is an agricultural college at Canterbury, well endowed, and provided with an excellent experiment farm. Secondary schools and district high schools are numerous, and scholarships are provided to assist young people of all classes to proceed to higher education.

## TASMANIA

Tasmania, with its 50 odd islands, covers 17,000,000 acres, of which about 5,000,000 have been sold or granted to the occupiers by the Crown, which retains 12,000,000 acres, some of which are on lease to settlers, who use them for running stock and for other purposes. Sheep runs, however, are limited, both in size and number, and cannot compare with those on the mainland. Tasmania is rich in valleys and plains, many of which are well furnished with timber, while running streams abound to the great advantage of the country, which in some parts is mountainous, the highest range reaching to 5,000 ft. in height. The richest soil is found in the north-west, but is to a large extent too heavily timbered for agricultural purposes until it has been cleared. The climate, warmer than England in winter, is somewhat hotter in summer; but the heat is regarded as less severe than on the Australian continent. In the interior of the country the rainfall averages about 18 in. to 21 in.; in the south 40 in. is reached; and in the east 27 in. The summer season commences with December. At the end

of 1904 the estimated population was 180,000, or 8,000 more than at the census in 1901.

**Crops.** Both climate and soil are suitable to the cereals and fruits grown in England, and to the large variety of other trees and plants which are known in this country, as well as to those which are indigenous to Tasmania. Owing to the great warmth, crops grow more rapidly, and although phosphatic manures are being employed, the farmers follow no regular system either of manuring or rotation, with the result that the yield of crops is smaller than in the old country. The produce of the chief crops grown in some typical years was as follows:

| Crops.                 | Acres.  | Year.  |
|------------------------|---------|--------|
| Wheat .. ..            | 49,414  | 1903-4 |
| Oats .. ..             | 60,663  | "      |
| Barley .. ..           | 8,084   | "      |
| Peas .. ..             | 11,156  | 1901   |
| Turnips .. ..          | 4,341   | "      |
| Potatoes .. ..         | 29,160  | 1903-4 |
| Hops .. ..             | 639     | "      |
| Gardens and orchards   | 13,231  | 1901   |
| Total land under crops | 259,611 | 1903-4 |

On the basis of ten years, wheat has produced 15 to 27 bushels per acre; oats, 22 to 38 bushels; barley, 13 to 32 bushels; and peas, which are grown on a small scale, 14 to 23 bushels; while hops have yielded from 1,400 to 1,900 lb. per acre. Potatoes, turnips, mangels, carrots, onions, and similar crops are grown, but in all cases the yield is smaller than in England. The grass area is increasing, the yield of hay averaging from 1 to 1½ tons per acre; in all, there are 340,000 acres sown to grass.

**Fruit-growing and Dairying.** With regard to fruit, and especially the apple, for which Tasmania is famous, many varieties are grown with success. Most of the orchards are in the south of the island, the crops being chiefly sent to the London market. The fruit grower needs more capital than the settler on a farm. Apple land costs £80 per acre to prepare, including £35 for the land, £20 for removal of timber, £12 for clearing the stones, and £13 for planting. As some years elapse before any substantial return is obtained, it is pointed out that about £130 per acre is spent before the trees reach the age of six years, after which the profits are correspondingly large.

Dairy farming is progressing, although both butter and cheese are still imported. Both climate and soil are suited to the production of milk, and there are butter factories and creameries, some of which are worked side by side with bacon factories, mostly run on co-operative lines.

**Wages.** Farm labourers, including ploughmen, obtain from 40s. to 60s. per month, including liberal board; while sheep-shearers obtain 11s. to 15s.; and shepherds from 30s. to 50s., including board and lodging.

Intending farmers are strongly advised to gain experience in the country before investing their capital, and this remark applies not only to the work of the farm but to the purchase of land. Although, as we shall show, land can be

obtained from the Crown, it will be found a wiser plan, with the aid of experience, and after careful examination of the country, to buy well-selected land from private owners, the cost of clearing Crown land being considerable. Some of the most useful grazing land is found in the north-west, north-east, midland, and south-east districts of the country, and in most cases stock can be left out of doors during the whole year.

In 1904, the number of cattle in the island numbered 186,000, these being chiefly Devons and Herefords. There were 36,000 horses, 57,000 head of swine, and over 1,500,000 sheep, chiefly Merinos, Leicesters, Shropshires, and Lincolns. In 1903, the quantity of wool exported was valued at £173,000.

The values of the chief exports of produce in 1903 were:

|                 | £       |              | £      |
|-----------------|---------|--------------|--------|
| Fruits .. ..    | 303,000 | Oats .. ..   | 90,000 |
| Wool .. ..      | 174,000 | Sheep .. ..  | 24,000 |
| Hides and Skins | 109,000 | Horses .. .. | 3,000  |
| Hops .. ..      | 42,000  | Wheat .. ..  | 4,000  |
| Potatoes .. ..  | 234,000 |              |        |

The settler will find, contrary to the practice in some other colonies, that there is both Income Tax and Land Tax, although neither may trouble him for some time. There is a Government Farm, near Hobart, where advice can be obtained by agricultural colonists.

**Cost of Land.** Cleared land of the first class costs, with the buildings erected, from £10 to £15 per acre. The area usually covers from 200 to 300 acres, while the capital required by the occupier is about £3 per acre; similar land may be rented up to 20s. per acre. Farms of the second class cost £6 to £10 per acre to purchase, and £2 10s. per acre to work, but may be rented at 7s. 6d. per acre. The cost of clearing land not hitherto under cultivation is £5 per acre, but partially cleared farms cost from £1 to £2 less. Crown lands which are partially cleared cost 15s. to 35s. per acre to clear; but before the plough can be used £20 to £30 may be expended. The Crown lands include (1) town lands and (2) rural lands—the latter being divided into first-class and second-class agricultural land. A settler of 18 years of age may purchase, if he intends to reside on and improve the property. Farms of 15 to 22 acres of first class cost 20s. per acre, payable in 14 years, but one-third of the price is added for credit; the sum of £3 6s. 8d. is paid on signing the agreement, and the balance by annual instalments. Second-class land costs 10s., and third-class costs 5s. per acre; for larger areas one-third is added in each case, and the instalment system is similarly adopted. Homesteads may be purchased at 20s. an acre, but the buyer must reside on the land for five years, and improve it to the value of £1 per acre; in all cases the buyer pays the survey fee. Land for grazing purposes is leased by auction up to 14 years at the annual upset rate of 5s. per 100 acres. Tasmania is more conservative than larger colonies, owing perhaps to its smaller size and the prosperity which is practically ensured.

## THE BEST BOOKS ON FARMING Agriculture

"Account of the Rothamsted Experiments." By A. D. Hall, M.A. (Murray, 10s. 6d.)

Deals with the experiments of the late Sir John Lawes and Sir Joseph Gilbert, discussing their purpose and results. The work is intended as an aid to all engaged in the management of land, to the agricultural student—who will find explanations of the various statements and conclusions which he reads in textbooks—and to the agricultural teacher and expert, for whom it provides much hitherto unpublished matter concerning the working of these great pioneers.

"Stephens' Book of the Farm." Six vols. Edited by James Macdonald. (Blackwood, Div. 1 and 2, 10s. 6d. each.)

Details the labours of the farmer, the farm steward, and the various workmen engaged on the farm. There is no branch of agriculture which is not well discussed. Well illustrated.

"The Feeding of Animals." By W. H. Jordan. (Macmillan, 6s.)

Deals with the conditions and problems involved in the feeding of animals, showing also the relationship between plant and animal life.

"The Elements of Dairy Farming." By James Long. (Collins, 2s.)

Deals with British dairy cattle, their management and feeding; with foods used in milk production; with milk, its testing analysis and commerce; with cream, butter, and cheese-making in principle and practice.

"The Elements of Agriculture." By W. Fream, LL.D. (Murray, 3s. 6d. and 2s. 6d.)

Produced under the direction of a committee of the Royal Agricultural Society, and divided into three parts: The Soil, the Plant, and the Animal.

"The Breeding Industry: Its Value to the Country and its Needs." By Walter Heape, M.A. (Cambridge University Press, 2s. 6d. net.)

Deals with the value of the breeding of stock, and the need of the work required for its advancement.

"The Pioneers and Progress of English Farming." By Roland Protheroe. (Longmans, 5s.)

Discusses questions relating to science and practice, agricultural depression, peasant proprietors, the distribution of land, landlords, local taxation, and agricultural labourers. In the appendix much information is afforded in relation to the Corn Laws, statistics, and local taxation.

"The Agricultural Note Book." By Primrose McConnell. (Crosby Lockwood, 6s.)

Crammed with information, for indeed it is a book of agricultural facts and figures relating to mensuration and levelling, weights and measures, machinery and buildings, labour, soils, manures, crops, stock and their food, dairying, forestry, and horticulture.

"The Small Farm." By James Long. (Smith, Elder, 6s.)

In this work a plan is sketched for the instruction and assistance of the small holder of land,

who is shown how and under what conditions livestock can be bred and fed with profit; and how a small area of land can be cultivated with farm and garden crops to the best advantage. The work is the result of practical experience.

"Modern Homesteads." By Samuel Taylor, F.S.I. (The "Land Agents' Record," Ltd. 17s. 6d. net.)

A practical treatise on the designing of farm buildings, houses, and cottages for farm labourers for holdings varying from three to 300 acres.

"Hints to Young Valuers." By Anthony R. Cragg, F.G.S., and J. R. Macdonald, M.A. (The "Land Agents' Record," Ltd. 20s. net.)

A most indispensable aid to the farmer and land valuer. It is crowded with information of the highest importance to landlords and tenant farmers.

"Agricultural Botany, Theoretical and Practical." By John Percival, M.A. (Duckworth, 7s. 6d.)

One of the best books dealing with the anatomy and physiology of plants. Gives the classification and special botany of farm crops, the weeds of the farm, and farm seeds.

"Permanent and Temporary Pastures." By Martin Sutton. (Hamilton Adams, 1s.)

A classic by the head of the great Reading seed firm, to whom we are indebted for several valuable illustrations.

"The Fertility of the Land." By J. P. Roberts. (Macmillan, 5s.)

"Ensilage in America." By J. E. T. Rogers. (Sonnenschein, 3s. 6d. and 1s.)

"Agriculture for Welsh Farmers." By D. D. Williams. ("Welsh Gazette," Aberystwyth, 7s. 6d.)

"Advanced Agriculture." By H. J. Webb. (Longmans, 7s. 6d.)

"Agriculture: Practical and Scientific." By James Muir. (Macmillan, 4s. 6d.)

"Silos for Forage Crops." ("Field" Office, 4s. and 6s.)

"The Principles of Agricultural Practice." By Prof. Wrightson. (Chapman, 5s.)

"Agricultural Experiments." By Dr. William Somerville. (Reid, Newcastle.)

"Fallow and Fodder Crops." By Prof. Wrightson, 5s.

"The Potato in Field and Garden." By W. J. Malden. ("Mark Lane Express," 3s. 6d.)

"The Business Side of Agriculture." By A. G. Rogers. (Methuen, 2s. 6d.)

"Principles of Agriculture." By L. H. Bailey. (Macmillan, 4s. 6d.)

"Irrigation and Drainage." By F. H. King. (Macmillan, 6s.)

"The Perplexed Farmer." By Georges Ville and Sir Wm. Crookes. (Longmans, 5s.)

"The Soil." By A. D. Hall. (Murray, 3s. 6d.)

"Tillage and Implements." By W. J. Malden. (Bell, 2s. 6d.)

"Conversion of Arable Land into Pasture." By W. J. Malden. (Kegan, Paul, 3s. 6d.)

"Food for Crops and How to Apply It." By C. M. Aikman. (Vinton, 2s.)

"How I Managed My Estate." (Bell, 2s. 6d.)

"Our Farm Crops." By John Wilson. (Blackie, 2 Vols, 6s. 6d. each.)

"How to Farm Profitably." By J. J. Mechi. (Routledge, 1s. 6d.)

"Farm Crops." By Professor Wrightson. (Cassell, 2s. 6d.)

"Profitable Home Farming." By Yeoman. (Cassell, 1s. 6d.)

"Revival of English Agriculture." By P. Anderson Graham. (Jarrold, 3s. 6d.)

"Farming." By W. M. Todd. (Dent, 7s. 6d.)

"The Farmstead." By Prof. T. P. Roberts. (Macmillan, 4s. 6d.)

"Farm Buildings." By W. J. Malden. (Kegan, Paul. 5s.)

"Elements of Agricultural Law." By A. Pearce Higgins. (Vinton. 3s. 6d.)

"Farm Valuations." By Leslie Wood. (The "Estates Gazette" Office. 4s.)

"Young Estate Manager's Guide." By R. Henderson. (Blackwood. 5s.)

"Bacon and Ham Curing." By L. M. Douglas. (3s. 6d.)

"Principles of Land and Estate Management." By H. H. Smith. (Arnold. 16s.)

"Landlords and Allotments." By the Earl of Onslow. (Longmans. 2s. 6d.)

"Plant Breeding." By L. H. Bailey. (Macmillan. 4s.)

"The Farmers' Friends and Foes." By Theodore Wood. (Sonnenschein. 3s. 6d.)

**HANDBOOKS OF THE FARM.** "Livestock," by Various Authors. "The Crops of the Farm," by Various Authors. "The Soil," by Prof. Scott and J. C. Morton. "Plant Life," by Maxwell Masters, F.R.S. "The Equipment," by Various Authors. "The Dairy," by James Long and J. C. Morton. "Animal Life," by Sir George Brown. "Labour," by J. C. Morton. "The Workman's Technical Instructor," by W. J. Malden. (Vinton. 2s. 6d. each.)

### Livestock

"Our Friend the Horse." By F. T. Burton. (Dean. 6s.)

Deals with almost all the British breeds of horses and a number of foreign varieties, as well as the ass and the mule. Contains chapters upon the rudimentary anatomy of the horse, its formation and teeth; subsequently dealing with stables, feeding, horsemanship and training, and the treatment of horses in accidents.

"The Thoroughbred and Other Ponies." By Sir Walter Gilbey, Bart. (Vinton. 5s.)

Deals with ponies past and present, together with a discussion of the racehorse and its growth since 1700.

"The Harness Horse." By Sir Walter Gilbey, Bart. (Vinton. 2s.)

Describes the various types of horse used in harness. Deals with the question of the supply of English breeding stock to foreign buyers and of our purchases from abroad. Discusses the question of the encouragement of breeding carriage horses, how we have failed, and how foreigners have succeeded.

"The Book of the Pig." By James Long. (Upcott Gill. 6s.)

Deals at length with the science and practice of breeding, feeding, and management; the construction of piggeries and sties; the influence of food in the production of weight; the diseases of swine; the curing of bacon and hams, and preparation of pig meat foods of various kinds.

"Horses and Stables." By Major-General Sir Frederick Fitzwygram. (Longmans. 5s.)

"Sheep: Their Breeds and Management." By Prof. Wrightson. (Vinton. 3s. 6d.)

"Light Horses: Their Breeds and Management." By W. C. Blew, M.A., W. Soarth Dixon, Dr. George Fleming, C.B., and V. Shaw, B.A. (Vinton. 3s. 6d.)

"Heavy Horses: Their Breeds and Management." By Herman Biddell, C. Douglas, T. Dykes, Dr. Fleming, C.B., Archibald Macneilage, Gilbert Murray and W. Trotter. (Vinton. 3s. 6d.)

"Cattle: Their Breeds and Management." By William Housman and Prof. Wortley Axe. (Vinton. 3s. 6d.)

"Sheep: Their Breeds and Management." By Prof. Wrightson. (Vinton. 3s. 6d.)

"Rational Pig Keeping." By W. J. Malden. ("Farm, Field, and Fireside" Office. 1s.)

"Livestock." By Prof. Wrightson. (Cassell. 2s. 6d.)

"Sheep Raising and Sheep Herding." By W. J. Malden. (Upcott Gill. 3s. 6d.)

"History of the Devon Breed." Edited by James Sinclair. (Vinton. 10s. 6d.)

"Farm Livestock of Great Britain." By Prof. Wallace. (Crosby Lockwood. 12s. 6d.)

"Pig Keeping." By W. J. Malden. (Kegan, Paul. 3s. 6d.)

"The Sheep." By George Armitage. (Warren.)

### Diseases of Stock and Crops

"A Treatise on the Diseases of the Ox." By J. H. Steel, M.R.C.V.S. (Longmans. 15s.)

This work treats of bovine pathology, and is especially intended for the use of veterinary practitioners and students.

"Animals of the Farm in Health and Disease." By Prof. Brown, C.B. (Murray. 1s.)

In this valuable little work there are no less than 52 illustrations, all of which are of great use to the stock owner, and for the reproduction of one of which in our own text we are indebted to the Royal Agricultural Society.

"Farm Insects." By Dr. Wm. Somerville, of the Board of Agriculture. 1s.

A most valuable elementary work of great help to students.

"Injurious Insects." By Eleanor Ormerod. (Sonnenschein. 5s.)

"Farm Vermin." By J. Watson. (Rider. 2s. 6d.)

"Diseases of Cattle." By Prof. Wortley Axe. (Vinton. 3s. 6d.)

"The Diseases of Sheep." By J. H. Steel. (Longmans. 12s.)

"The Sheep Doctor." By G. Armitage. (Warren. 10s. 6d.)

"Diseases of the Pig." By Prof. Wortley Axe. (Vinton. 3s. 6d.)

"Diseases of Plants." By Prof. Marshall Ward. (Macmillan. 7s. 6d.)

"Timber, and Some of its Diseases." By Prof. Marshall Ward. (Macmillan. 6s.)

"The Farmers' Veterinary Guide." By G. H. C. Wright, LL.D. ("Farming World," Edinburgh.)

### Manuring and Chemistry of the Farm

"The Chemistry of the Farm." By R. Warington, M.A., F.R.S. (Vinton. 2s. 6d.)

Deals with the growth of plants, with the atmosphere and the soil, manures, crops and their rotations, animal nutrition, foods, the relation of food to animal requirements and to manure; and, lastly, with the chemistry of the dairy.

"Artificial Manures: Their Chemical Selection and Scientific Application to Agriculture." Translated and Edited by Sir W. Crookes, F.R.S. (Longmans. 21s.)

This work, written by the famous French scientist, Georges Ville, deals with his great theory of intense cultivation.

"Agricultural Chemistry." By R. H. Adie and T. B. Wood. (Kegan. 2 Vols. 3s. 6d. each, net.)

"Fertilisers and Feeding Stuffs." By Dr. Bernard Dyer. (Crosby Lockwood. 1s.)

"Soils and Manures." By J. H. Munro, D.Sc. (Cassell. 2s. 6d.)

"Manures and the Principles of Manuring." By C. M. Aikman. (Blackwood. 7s. 6d.)

"Fertilisers." By Prof. E. Voorhees. (Macmillan. 4s. 6d.)

"Introduction to the Chemistry of Farming." By Sir T. Dyke Acland. (Simpkin, Marshall. 2s. 6d.)

# UNDERCLOTHING

Cutting Out and Drafting of Various Patterns of Chemises,  
Cycling Knickers and Divided Skirts. Combinations

By AZÉLINE LEWIS

WE now proceed with the cutting out of the garment first in request. In 25, five shapes of chemise are illustrated: (a) The "grandmother," or "working woman's chemise," which is liked by many for its simplicity of cut; (b) the ordinary shape; (c) the Princess shape, especially suited to stout figures; (d) the French pattern, also adapted to stout figures, and forming chemise and petticoat if wished; (e) the Empire pattern for evening wear.

When measuring for chemises, the length is usually taken from shoulder to knee. The width may be from three-quarters to seven-eighths of the length; but for this no hard-and-fast rule can be given, as very stout or very slight figures may require a little adapting to their special needs.

**Chemises.** To cut, fold over the material, which we will presume to be 36-in. calico, to the length required. Fold this in half lengthways, then mark the middle of this as at E and F [26]. Mark off from A to G three-quarters of the folded width, or one-quarter of entire chest measure, and slope this off to F, and thence to H. This sloped piece is added to the lower portion, from F to D, to give the additional width required. If the wider makes of calico be employed, this addition is not required, and the shoulder can be sloped down to the edge of the material.

For the neck, mark I one-eighth of entire length, and slope up to J. Slope out for back the same, making this 1 in. higher. Mark, but do not cut till the chemise has been opened out, or the two sides may be cut alike. It would be right, however, if the back only were cut and the front sloped out afterwards.

The sleeve is a straight strip about one-third of the length measure and the width required. Fold this in half, the fold to come to the shoulder [26a].

The gusset is a square one, quarter the length of sleeve. To obtain the square, measure

off one-quarter of length, then fold over cornerwise, and make the other side exactly the same length [26b].

About 2½ yd. of material are required. To make this chemise, seam on the gored piece, unite sides by a run-and-fell seam, and hem the lower edge. The neck will require an opening 5 in. or 6 in. in length in centre-front, which should

be finished off with a mitred wrap on the right side and a hem on the under edge [25]. The neck part is gathered in the front and back, about 4 in. either side of centre in each case, and inserted into a narrow band which, if of material, must be cut selvage-ways; but this may be formed of insertion if preferred.

For the sleeve, sew one side of gusset to lower edge, level with long edge; then fold it triangularly, and sew the other edge to the lower edge of the sleeve [26a]. The gusset edges should be secured to sleeve by a run-and-fell seam.

Another sleeve may be cut as (c) in diagram 26. For this, take a square of paper equal to one-quarter of the length measurement, and fold cornerways, making the sleeve from A to B the width preferred on the shoulder, as this is quite a matter of taste, some liking deeper sleeves than others. C to D should be 1 in. to 1½ in. wider than from A to B, and is sloped out to this. The sleeve may be made with a seam on the shoulder, or at the fold, as preferred. If the former, place the top portion to a fold, and vice versa.

Another pattern of chemise has the sleeve all in one, and is a little more shaped than the other [27]. A to C and B to D are the length required. A to B and C to D about one-third of length. A to E, seven-eighths of half-width; B to F, length of sleeve opening, one-eighth of length, plus 2 in. (this may be varied a little

according to size of arm). Curve gradually from E to F. Make G one-third of length, 3 in. from line B—D, and curve from F through G, sloping out to D for side of chemise. A to H, half of

25. VARIOUS SHAPES OF CHEMISES

26. SIMPLE CHEMISE

27. PLAIN CHEMISE

width, plus 2 in., then curve neck as in previous draft.

For this chemise, 2 yd. to 2½ yd. will be required, according to length. The making is somewhat simpler than the latter, as the sleeves are cut all in one.

These two diagrams represent the usual shapes, from which all other variations can be easily evolved. For instance, if required not so full, the distance from A to E and H may be decreased, as well as at F, while the slope in at G may be greater. Again, the neck may easily be cut square or pointed, or any other shape preferred, and either fastened at the shoulders or in the front. If the former, the shoulder part need not be placed to a fold.

**Princess Chemise.** This shape is particularly suited to those whose figures incline to stoutness, as there is no superfluous fullness at the waist part. The pattern is easily evolved from the bodice drafting of the Princess gown shown in *TAILORING* [page 2205], except that it has no side or under-arm piece, and the skirt portion is not quite so full [28].

The opening may easily be made rounded, if required, and, with very little alteration of the back dart, the pattern may easily be made into a long vest, particularly suited to those who are no longer in their first youth, in which case flannel would be the material required.

The French pattern which is shown at (d) in 25, is much liked by stout figures, two parts—viz., bodice and skirt portion joined together at the waist, the latter with a gathered frill. The bodice part may be cut either with one or two bust darts, like an under-bodice, or with the dart carried to the shoulder, as in the Princess chemise, in which case the bodice portion of diagram 28 would do. If the former be preferred, the bodice drafting to the required measurements should be consulted, but, of course, must be enlarged. It might also be cut in one piece, for which see CAMISOLE.

The skirt portion, too, may either be cut exactly like that of the Empire coat in *TAILORING*, without seam at centre-back, or it may consist of two straight widths joined and

gathered on to this, the former being preferable for a chemise, particularly if the material be not very fine. In this chemise the under-arm seams

should be run and felled, but all the others should be united by means of a beading, as well as the skirt, which has to be secured to the bodice at the waist; whilst the flounce at the lower edge should be put on in the same way. The opening may be either at the front or the shoulders, whilst the neck and sleeves may be trimmed according to taste. This chemise will require 4 yd. of 36 in. or 40 in. madapolam or cambric.

The Empire chemise shown in 25e has the bodice cut to fit somewhat closely to the figure, and may be made entirely of embroidery, as shown, or material and lace, whilst the neck edge may be quite straight if wished.

**Knickers.** We will next deal with the knickers. Fig. 29 illustrates four different patterns and a divided skirt: (a) the ordinary shape with yoke-band; (b) knickers closing at back; (c and d) wide-legged French patterns; (e) special cut for stout figures; (f) a divided skirt.

The length is generally measured from hip to knee, with a little over if set into a band, or according to taste, and the width is usually considered from 1¼ to 1½ times the length.

Fig. 30 shows the ordinary shape made with a yoke or shaped band. A to C and B to D is the length; A to B and C to D the width. E and F are three-eighths of the length counted up from C and D for inner leg measure.

Make dots and draw a line. A to J, 2½ in.; curve from J to E. B to H, one-eighth of length; H and I the same distance, at right angles. Curve from I to F for front upper leg, also from J to I for waist.

C to L, 6 in.; D to K, the same. Curve from E and F to L and K for lower leg-seam.

To draft the band, take a square of paper half of waist measurement, shown by A, B, C, and D; mark from C to E, one-third of depth; B to F, the same. Lower F 1 in. and

slope from G to B; then curve from G to E for upper waist edge, and from B to C for lower width of band [31].

28. PRINCESS CHEMISE

29. KNICKERS AND A DIVIDED SKIRT

It is made in two parts—viz., bodice and skirt portion joined together at the waist, the latter being terminated

30-31. PLAIN KNICKERS

These bands should be a little larger than the exact measurements, as they should always be worn a little below the waist curve. If the band be required to be deeper or more pointed in front, this alteration must be made at the lower curve; the upper one should not be interfered with.

These knickers may be made open or closed at the back, as preferred. If the latter, the opening must be made at the side at the fold of outer leg, and the knickers would be set into the band round the front only, as far as the opening, the back portion being arranged into a narrow band buttoning on to this from each side of the opening [296].

To make the open knickers, join lower leg portions as shown by notches, by a run-and-fell seam; join centre front a few inches down from I, either by a run-and-fell seam, and hem from here to J, or hem the whole of the upper front leg parts a few inches down from I, by seaming or oversewing very firmly.

The waist-part is gathered and secured between the lower edges of the band as indicated by the notches. The fullness must be regulated so that there is a little more at the back than the front. The band may be fastened by a tape run in at each end [32], or buttoned, the latter being less bulky. The trimming and finishing of the knee-part is a matter of taste.

Fig. 34 depicts the wide-legged French knickers which so many prefer. They are usually curved upwards at the outer leg, in which case they would be left loose; if made straight they can be drawn in by slots, through which ribbon is run, so that they may be easily opened out for laundering purposes. This shape fits closely to the waist, so requires no band, the waist part being neaten by a crossway strip of material.

A to B, half of waist measure. A to C, half of this measure. C to D, length of outer leg to knee. E and F, midway between A and D. E to F, half width. B to G, 1 in. more than from A to C. Curve to the various points marked. D to I may be varied somewhat; in the diagram it is 15 in., half width, whilst the length from E to D may be lessened, as many prefer this shape made with deep frills.

Fig. 33 gives another French shape, wider in the leg. The trimming of the leg-part of either of these shapes is a matter of taste.

We now come to a pattern specially designed and intended for stout figures, which differs

entirely in construction from the accepted shape, but is one we can most thoroughly recommend for comfort and roominess, thus obviating that dragging which is so often complained of in the ordinary pattern. This model while giving plenty of freedom, owing to its shape, is yet arranged to have no superfluous fullness at the waist part, no band being required, the shaping being effected by means of deep darts [35].

When the leg portion is folded, as indicated by the broken lines, the two notches meet for the leg-seam, which will come a little further back than in the ordinary shape. The point

of the curve extends a little way up the back, and the whole of this from the top of waist at back to the centre front must be neaten by a strip of crossway material stitched to it, as, owing to the curve, tapes or a hem are inadvisable.

The darts should be fitted before being cut, as stout figures vary so much; when correct they should be joined by a narrow run-and-fell seam, and the waist part finished off with a crossway strip of material.

**Cycling Knickers and Divided Skirts.** Of late years knickers made of woollen materials have almost entirely superseded the flannel petticoat. They are made in various shapes, but nearly all can be evolved from the pattern shown in 30, according to the directions given for closed knickers (see also 296). From the yoke-band there shown, it will be easy to arrange any other modifications. The side-openings would be finished off with mitred wraps.

A Divided Skirt—which is a term often loosely applied to knickers—is shown in diagram 36, the making of which should present no difficulty. It can have several flounces if preferred.

Knee-bands for long-cloth drawers vary from 15 in. to 18 in. long, the width about  $\frac{1}{2}$  in. to 1 in. when finished.

The quantity required for plain knickers for average figures is 2 yd. to 2½ yd. of 36 in. material.

**Combinations.** The combined garment has come into special favour of late years, and is now almost universally worn in place of chemise and knickers.

Fig. 37 illustrates a simple drafting of the ordinary shape, with fullness gathered to the back part.

The length is measured from the top of shoulder to below the knee.

32. BAND

33. SKIRT KNICKERS

34. FRENCH KNICKERS

35. KNICKERS

36. DIVIDED SKIRT

The lower portion is cut exactly the same as the knickers in 31, so we will only consider the upper part.

A to M, one-quarter of the width; B to P, one-eighth. H, midway between A and B; and O midway between B and H.

2 is  $2\frac{1}{2}$  in. to the right of line M—1, and  $2\frac{1}{2}$  in. below G. M to L, one-eighth plus 1 in.; M to 1, one-eighth of width; P to 6, one-quarter. (These two measurements must vary according to whether the garment is to be high or low-necked.) L to 3, 3 in.; drop  $\frac{1}{2}$  in. and draw line to L for back shoulder.

H to 5, the same as A to M; curve from 3 and 4 to 5 for armhole, curving front a little more inwards than the back. 4 to N, 3 in.; raise 1 in. and draw from this to 4 for front shoulder, then curve from point above N to 6 for front neck.

5 to 7, 14 in.; make 8 and 9 1 in. to right and left at waist, and curve through each to 7. 10 is 1 in. below 5 on line O; 10 to 11, 10 in.; curve from 10 to 11 1 in. to right and left at waist. Curve from 6 to F for front line.

Fig. 38 gives another shape cut all in one. It may also be made in flannel for winter wear. The lower portion, it will be

seen, is cut similar to the German shape knickers shown in 35, and is put together in the same way as far as the leg part is concerned.

The neck, as in chemise [27], may be cut square or pointed, as preferred. If made high to the neck, the bodice measurement should be consulted. In the making care must be taken to keep the darts even. A wrap may be left down the centre front, as shown by the broken line, but in any case the curved part should be faced with a strip of material cut to the same shape, as directed for the knickers.

Sleeves are also a matter of taste, many chemises and combinations being now made without them, and the armhole finished off with insertion and embroidery, or deep frills. If a sleeve be required, that shown at C in 26, curved slightly at the lower armhole portion, will be a good example. For evening wear the shoulder part of an armhole would be omitted, and ribbon or narrow insertion and lace take its place for a shoulder-strap, as in the evening chemise.

For plain combinations,  $2\frac{1}{2}$  yd. to 3 yd. of 36 in. material is the usual allowance.

**The Nightdress.** Nightdresses may be made with or without yokes, either of the shoulder or Empire variety, but are nearly all made without collars or with just only a frill of material, whilst some of the more elaborate kinds are low-necked and cut either square or round.

The sleeves, too, vary from the bishop to the full elbow sleeve, or only a full, deep frill.

The skirt portion is generally shaped a little at the sides, and should be generous as to fulness at the foot part.

The most generally approved shape, however, for an ordinary nightdress is that made with a square yoke cut all in one [39]. The skirt portion is marked with the average measurements, but may easily be altered according to the height or size of the wearer. The broken line shows where the pattern may be sloped out if needed [40].

For the yoke, take a piece of paper 26 in. deep and 48 in. wide, and fold it in half. A to B is  $5\frac{1}{2}$  in.; B to C, 8 in.; draw line for front edge. D to E, 8 in.; curve from C to E for shoulder. D to F, 5 in.; F to G, half-neck measurement, less 1 in. for curve; G to H, 2 in.; curve from H to F for neck [41].

The sleeve can be of the bishop order, for the cutting of which full directions were given in DRESSMAKING. [See also 51.] The front opening is finished off with a mitted wrap of material or insertion, and should be 14 in. to 16 in. in length. This is run on and either stitched or feather-stitched at each edge. The simplest method of cutting out the skirt part for the smaller sizes is to cut a length of material twice that required, fold it in half, and then slope off one side from 2 in.

to 8 in. or 9 in. This sloped piece can then be added to the straight side, with the wider part at the lower edge. For larger sizes join two half-widths—the latter taken lengthways—fold these in half and cut the two-gored skirt portions.

# THE IMPERIAL SERVICE

State Prizes in India and the East. Indian Civil Service. The Forest Service. Eastern Cadetships. Police and Professional Appointments

By ERNEST A. CARR.

THE Imperial Service, which we are to consider in this and succeeding numbers, forms the last great division of our general subject, the CIVIL SERVICE. In many respects it is also the most attractive—at least for that great race of “adventurous youth” whose passing certain pessimists among us have prematurely mourned of late. For the most part the Imperial Service offers a strenuous, eventful career in some far quarter of the globe, with greater hardships than attach to a life of official routine at home, but also with much greater chances of distinction and success.

Embracing, as it does, our numberless colonies, dependencies, and possessions, and comprising both State and municipal employment, the Imperial section is in itself fully as varied and comprehensive as the home services whose survey we have concluded. But it is important to bear in mind that while appointments in this service are in some instances accessible to candidates in Great Britain, many others are reserved for local patronage or competition. Particularly is this the case in our greater colonies, such as Australia and South Africa, whose civil officers of every grade are recruited almost entirely from local sources.

Where such conditions of employment prevail, an exhaustive description of the service would be useless. The course we propose to follow, therefore, is to discuss at length those posts for which British aspirants can enter, and to deal more briefly with the rest, while indicating the source from which fuller information as to these latter appointments may be obtained.

## INDIAN CIVIL SERVICE

Some of the finest administrative and judicial positions in the Indian Empire are brought within reach by success at the open competition held every August for probationary appointments in what is termed the “covenanted” Civil Service of India. The expression refers to the covenant or contract which every successful candidate has to execute with the Indian Government, and is used to distinguish this from a subordinate service that is filled chiefly by patronage in India.

For ambitious young students who are not daunted by the prospect of exile and a trying climate, the “I. C. S.,” as it is generally called, offers prospects far more brilliant even than are afforded by Class I. clerkships in the home service.

The examination is open to all natural-born subjects of His Majesty (including Indian natives) who are between 22 and 24 years of age on August 1st of the year in which they

enter. No deduction of age on account of military or other service is permitted for these posts. As already explained [see First Class Clerkships, page 2250], a joint competition is held for the Indian Civil service, Eastern cadets, and clerks in the home service, eligible candidates choosing, in their order on the combined pass-list, which service they elect to enter.

The official regulations as to these annual contests may be had on application to the Secretary, Civil Service Commission, Burlington Gardens, W. On the subjects prescribed, and the very searching character of the papers, nothing can usefully be added to the information given on page 2251.

“**Selected Candidates.**” Successful competitors who choose the Indian service are known as “selected candidates.” They are on probation in England for a year, studying Indian law and history and the language of the province to which they are assigned. An allowance of £100 is granted to those who spend this term at a university or college approved by the Secretary for India. The probationers must then pass an examination in their studies, the cost of failure being withdrawal from the service. They are also tested in horsemanship.

Selected candidates who acquit themselves creditably at the final test are provided with a free first-class passage to India, and on arrival receive appointments at a salary beginning at 4,500 to 5,000 rupees per annum. Taking the average value of the rupee as 1s. 4d., this represents about £300 to £330 a year. The actual value is usually somewhat higher. The conditions of employment are generous, every year of actual service entitling the young civilian to three months’ furlough—which may be accumulated to permit of a prolonged visit home. After a time the officer is called upon to choose which branch of the service he will follow—the judicial or executive. The former may lead him eventually to a judgeship in the High Court, the latter to the rank of Lieutenant-Governor of a province. Apart from such great prizes, opportunities for distinction are not wanting in the service; and if the individual has the ability and energy to seize them, his advancement is likely to be rapid. Many members of the I. C. S. reach responsible and highly paid positions, such as that of judge or magistrate of a native court, while still young in their calling. After a quarter of a century—21 years of which must have been effective service as distinguished from furlough and sick leave—the Indian Civil servant is entitled to retire on a life pension of £1,000 a year. Ten years later his retirement becomes compulsory.

## EASTERN CADETSHIPS

These positions have been instituted to supply the higher ranks of the Civil services of Ceylon, Hong Kong, the Straits Settlements, and the Federated Malay States with trained and capable officers. They are filled by open competitions held every August concurrently with those of the Indian Civil Service and for Class I. posts; but their inferiority in value is shown by the fact that they generally fall to men low down on the combined pass-list, higher placed candidates having selected the other services in preference. Thus, at a recent joint contest, the first man to accept an Eastern Cadetship had taken only the 56th place on the list. Still, these posts are distinctly attractive ones, with a fair salary from the outset, and good though not dazzling prospects.

The examination subjects are the same, of course, as for Class I. appointments, and the same age limits are fixed—namely, 22 to 24; but for cadetships no deduction from age is permitted except for service in the Militia or Volunteers during the Boer War. Candidates must be of sound constitution and good eyesight, and fit for tropical service. Except for Ceylon, it is specified that cadets shall be of European descent.

Selected candidates are required to leave England about a month after passing, and receive a free passage, half-pay on embarking, and full salary on reaching their destination. In Ceylon their remuneration as cadets is 3,000 rupees a year, with a pundit allowance of 360 rupees for instruction in the native language; in the other colonies it is fixed at £225. The routine of training is practically the same in all cases, the cadet dividing his time between his studies in the native tongue and instruction in Government business. On passing his examinations he receives an immediate advance of pay—in Ceylon to 3,500 rupees, elsewhere to £300—and becomes eligible for a permanent appointment with a salary usually beginning at £360 or £420 a year. Thence, as he rises in grade, his income progresses to £900 or £1,000 at the least; and there are further possibilities before him up to £2,000 or more.

## INDIAN FOREST SERVICE

A hardy young fellow in quest of an open-air calling, and undismayed by exposure and fatigue, could scarcely find a more tempting career than is afforded by the Forest Service of India. It involves much lonely service in the remoter regions of our great Eastern Empire, often far from white men; but to those who have heard "the call of the wild," and cannot forget its voice, there are ample compensations in the eventful, unhackneyed days passed amid some of the grandest and most beautiful scenery in the world.

One essential feature of the forest service is the costly training that precedes it, for which an allowance of about £200 a year for three years is necessary. Many likely men are debarred by lack of the requisite means, and thus it arises that, despite its attractions, the com-

petition for vacancies in the service is not very severe.

Examinations for some eight or ten appointments as probationers are held in the summer of each year—usually in August. They are open to every unmarried British subject whose age, on the first day of the preceding January, was between 18 and 21 years; but only those candidates are selected who have passed, or who undertake to pass before the following October, the test known as Responsions at Oxford, the Previous Examination at Cambridge, or some equivalent examination. The competition for appointments consists of papers and practical work in each of the following branches of science: (1) Mechanics and physics; (2) Chemistry; (3) Botany.

Candidates must qualify in all three subjects, and must also show sufficient knowledge of German—the test in which comprises translation, composition, and conversation. The examination fee is £2.

**Probationers.** Successful competitors are required to pass a strict medical examination, at which particular stress is laid on good vision and hearing. They are then appointed on probation for three years' training. During the first two years they pursue a special course of study at Oxford University in forestry and allied subjects, defraying their own expenses meantime. In the third year they receive practical instruction on the subject of their future calling, visiting various Continental forests for the purpose. To cover their travelling expenses and the cost of their board, lodging, and other charges during their final year, probationers are required to pay to the Secretary of State for India £60 a term, or £180 in all.

On completing their training, probationers who have obtained the diploma of Forestry at Oxford are appointed second-grade assistant conservators in the Indian Forest Department, and proceed to take up their duties. They must take their own passages for India, but receive an official allowance varying between £50 and £100 according to their proficiency.

### Pay and Prospects of Conservators.

From the date of their arrival in India, assistant conservators draw 350 rupees a month (about £300 a year) increasing to 450 rupees on entering the first grade. They are appointed to one of the great timber divisions—Burma, Assam, the Punjab, or elsewhere—and are entrusted with the protection and improvement of the forest land within their section, the reafforestation of denuded areas, and similar responsible and interesting work.

The higher ranks are remunerated as follows, the figures being given in rupees per month: Deputy conservators, 550 to 900; and conservators 1,200 to 1,600. The proportion of superior posts is very large, and advancement is therefore speedy.

The official regulations as to these appointments, with particulars of salaries and pensions and a syllabus of the entrance examination, may be obtained on application to the India Office, Whitehall, S.W.

## POLICE. APPOINTMENTS

Although police duties are vastly less interesting than forestry to the normal mind, the examination for the Police Service of India and the Further East attracts a great many more candidates every year than that for the Forest Service—and this for a sufficient reason. Success at either contest is followed by a term of probationary training; but whereas the future conservator of forests, as we have seen, has to study hard during three costly years before earning a rupee, the police probationer is receiving over £200 a year within three months after passing his entrance examination.

As in the case of the cadetships already discussed, a single examination is employed to recruit several police services. The competition is an open one, and is held every June, or thereabouts, for such vacancies as then exist in India, Hong Kong, the Straits Settlements, and the Federated Malay States. Candidates may enter for all appointments at the same time on payment of a single fee of £2 (or £3 if examined elsewhere than in London); and are required, if successful, to make their selection as soon as the result of the competition is announced. By far the greatest number of vacancies arise in the Police Service of India.

**The Examinations.** Unlike most open Civil Service examinations, these competitions are not advertised in the public Press. Applications to compete must be made not later than May 1st of each year, on a printed form obtainable from the Secretary, Judicial and Public Department, India Office, S.W. Candidates must be unmarried, and between the ages of 19 and 21 on June 1st of the year in which they compete. An extension of not more than eighteen months is granted to those who served in the South African War.

The examination is in English, and not more than four of the following subjects: Mathematics, higher mathematics, Latin, Greek, French, German, history, and science—to each of which a maximum of 2,000 marks is assigned. Candidates may also take up freehand drawing, which carries only 250 marks.

Those who are successful at the literary contest must next undergo a strict medical examination as to their physique and capacity for active outdoor work on the plains of India or elsewhere. On satisfying the Civil Service Commissioners of their ability to ride, they are then appointed as probationers at one of the districts in which a vacancy exists, their wishes on this point being consulted as far as practicable. They are provided with a free passage out, and must embark in the October following the examination.

A probationer who is sent to India receives 250 rupees a month while under instruction in police duties and in the local language. On passing certain examinations in these subjects—a task that must be achieved within two years of his arrival in India—he is appointed Assistant Superintendent of Police at 300 rupees monthly,

rising to 500, and has excellent chances of becoming District Superintendent, with a salary of 1,000 rupees per month. There are also a few higher posts within his reach. In the other services probationers are paid £225 a year on arrival, and £300 after passing the departmental examinations. On receiving an appointment they draw a salary of £350, rising to £660, and if fortunate, may reach £1,000 a year. Free quarters are provided for officers of all grades.

**Subordinate Posts.** For the most part, the police rank and file in the East are native officers. In Hong Kong, however, there is a British force which is largely recruited by volunteers from the home constabulary. Police constables are engaged for five years or longer, and are paid 50 dollars a month, with an allowance for depreciation of currency amounting to another 10 or 15 dollars. For proficiency in Chinese they may receive a further allowance of 2 dollars 50 cents to 10 dollars monthly. Promotion is said to be no faster than in the home forces, the sergeant's stripes taking six or seven years to win.

## OTHER INDIAN APPOINTMENTS

In addition to the services already discussed, there are others for which only those candidates are eligible who have been specially trained in one of the professions. Such appointments have little interest for a student of this course, their place being among the professional groups of the SELF-EDUCATOR. For present purposes they may be dismissed in a few words of description, coupled with a reference to official sources of information for the benefit of persons who may be interested.

**Public Works and Telegraphs.** Trained engineers from the technical colleges are now eligible for valuable appointments in these services, which were formerly reserved for the men of Cooper's Hill College. Salaries range from 4,200 to 30,000 rupees a year. The regulations can be obtained of the Secretary, Judicial and Public Department, India Office, S.W.

**Veterinary Posts.** Candidates possessing the M.R.C.V.S. diploma have a chance of entering the Indian Civil Veterinary Department on attaining the age of 26. The pay and prospects in this service are good, but officers are debarred from private practice.

**Education and Nursing.** Appointments in the Indian Educational Service are under the patronage of the Secretary of State, who usually awards these to distinguished graduates of British Universities. No limits of age are prescribed. Officers are engaged in the first instance for a term of five years, at an annual salary of 6,000 rupees, rising by 600 rupees yearly to 8,400. There are good prospects of promotion if the period of engagement is extended.

Trained nurses between 25 and 35 years of age are appointed by the Secretary of State to the Indian Nursing Service, on terms that can be obtained on application to the Under-Secretary, India Office, S.W.

VEHICLE CONSTRUCTION  
continued from  
page 329

By H. J. BUTLER

A WELL-painted carriage is not only the combination of a highly-finished surface and a well-preserved structure, but the many lengthy processes employed in the preparation of the woodwork give a result which is unequalled in other branches of the painting trade. It is the painting that prevents a finished carriage from being turned out quickly; the woodwork, smithing, and trimming may be quickly done if plenty of hands be put to the job, but as yet the unrivalled durability of a coach panel cannot be attained under from 21 to 28 days.

**Hurried Painting.** In the motor-body trade, the manager is often called upon to turn out a job by an impatient customer in a state that does not do justice to the traditions of his firm, and one may often notice at the motor shows many evidences of hurried painting. There are on the roads many automobiles which were taken out before the varnish was hard, and then driven at a high speed, thereby forcing the dirt and dust into the surface of the paint.

Motor-cars, as a whole, give evidence of less time having been expended on the painting, no doubt owing to the enthusiasm and impatience of the customer and to the fact that a well-painted body requires time for its execution. The coachbuilder may justly grumble at this state of affairs, which has existed for so many years. The painting department has shown very little progress and great absence of inventiveness.

However well the bodymaker may finish his woodwork, or the smith his ironwork, it is in the power of the painter to make or mar the result. The exertion expended in a well sand-papered panel is lost if improperly varnished, and the mouldings and consequent outline of the body will be spoilt if the workman be not expert with his pencil. Likewise the shape and proportions of the ironwork and, to a greater degree, the carving may suffer at his hands if he be careless.

**Priming.** The body, having been removed to the paint loft, is first subjected to a thorough overhauling with the dusting tool, and is then given a coat of lead colour (made of 2 lb. ground white lead,  $\frac{1}{2}$  pint linseed oil, a little driers, and some lampblack to render it more opaque) all over, both inside and outside, the stuff being applied evenly and thinly with a good stiff brush, care being taken to work the paint well into corners and pin-holes.

The first coat of priming is allowed at least 12 hours to dry, and longer in winter. A second coat of lead colour with more oil in it than the

first coat is applied after the first has been finely glass-papered off, avoiding cutting through the paint at the projecting angles of the body, and, when dry, the roof covering is proceeded with, care being taken to remove superfluous paste.

**Leather Covering.** In carriages such as broughams, the roof and upper quarters are covered with russet leather, which serves as a strengthening medium and conceals joints and pin-holes. The edges of the hide and the pins by which it is fastened are hidden by the bead and cornice. The leather is sleeked on wet, the parts first being evenly covered with a paste to facilitate adhesion, and allowed four or five days to dry.

This leather is put on in one piece, and we can understand that to save expense the roof only is covered in some instances, and should any damage be done to the quarters the consequent removal of the leather from both roof and panels makes such a repair expensive. Lead colour will not adhere to this leather covering, for we should find the oil sinking in, leaving the lead like a powder on the surface; so it has to be prepared by giving it two coats of equal parts of gold size, black japan, and turpentine, or a small piece of white lead about the size of an egg is added to a tablespoonful of japan gold size mixed with  $\frac{1}{4}$  pint of black japan. The mixture is applied heavily, and two days are allowed for its application and drying.

**Stopping up.** One might think that we may now proceed with the blue or green or whatever colour the body is to be, but there is the "filling up" and "stopping up" to be done first. This latter process consists in puttying up the under-carriage and ironwork with a mixture made up of linseed oil, dry white lead, and gold size or japan to hasten the drying. "Hard stopper" (dry white lead, turpentine, and gold size) is used to fill up screw and pin holes. Both putty and stopper are glass-papered when dry. This operation may be done after the second coat of lead colour, or after the rubbing down. Perhaps the former practice is the prevailing one.

**Filling up.** Filling up consists of yellow ochre, spruce ochre, and umber, together with tub lead and turpentine. Gold size and japan are added to make a fairly stiff cream. Filling-up powder may be bought ready for mixing with lead, turpentine, and other ingredients. Proportions vary with different mixers;  $2\frac{1}{2}$  lb. of ochre ground in turpentine to  $\frac{1}{2}$  lb. of white lead and  $\frac{1}{2}$  pint of varnish bottoms or similar ingredients indicate the general practice. Either five or six coats are applied one after

the other, quirks and similar recesses being avoided. The first coat requires to stand four hours, with two hours interval for each succeeding coat, but many assert that 12 to 24 hours is necessary between each coat.

**Staining.** The filling-up is followed by a coat of staining or guide colour, which is made of lampblack thinned with turpentine, and is therefore darker than the filling-up underneath; consequently, when the rubbing down takes place, the workman can at once see where his work has yet to be done. The conclusion must not be drawn that the rubber-down has to efface all the staining coat, but by feeling the surface with his hand he must use his discretion as to when the operation is completed.

**Rubbing Down.** The rubbing down is effected with pumicestone and water, and in the case of a brougham begins at the roof, working downwards over the upper quarter and so on to the bottom arch-panel. The hand that is not rubbing may be used to feel how the work is progressing. The parts that cannot be rubbed with the piece of stone may be done with pumice-powder and a cloth. As the rubbing proceeds a sludge is created with the filling-up, which must be removed with a rag dipped in water. The block of stone in the hand may be cleaned with a brush and water from time to time as it clogs, and, when necessary, faced level on another piece of pumice or other stone.

When the rubbing down—a laborious and tedious process—has been completed, the body is sponged off, and finished with a washleather. After allowing from 12 to 24 hours for the body to dry, very fine glass-paper or a loose branch of hard, loose hair is passed over the surface, giving it a tooth ready to receive its next coat—one of lead colour.

**Lead Colour Coat and its Facing.** This colour is made with or without lampblack, according to the final colour of the body. A yellow panel will require a different shade to a dark blue.

When dry, this is again faced with pumice, but the process is by no means so laborious as the rubbing down, for the paint ought not to be cut through.

**Ground and Best Colour.** We have now a fine smooth surface ready for the ground colour, which is of a lighter tint than the final coat of body colour. Having allowed the work to stand for a day, we apply in succession two coats of best colour, the black parts, such as the hoot and quarters, receiving two coats of japan. Next we apply the varnish colour or the required pigment, ground in turpentine and mixed with flattening varnish. Sometimes this is to enrich the tone of the best colour, or to create a different shade on a more solid under coat. Any paint of a fugitive nature cannot be used in the first colours of paint.

**Flattening.** As facing is more delicate than rubbing down, so flattening requires a lighter touch than facing. It is effected with pumice dust on a cloth pad or a piece of felt. This process deadens the brightness of the varnish colour. The flatted surface is well washed off with water,

and when thoroughly dry a coat of flattening varnish is put on.

Whether one or as many as three coats of flattening varnish be applied, the surface is flatted in each case with pumice-dust. After the flattening is dry, we come to the edging, picking out, or fine lining, of which several varieties are shown in 55 [D to M]. This consists of the fine lines of colour applied with suitable pencils to the mouldings, so emphasising the outline, and various forms of similar decoration are added to the spokes, felloes, and different parts of the under-carriage.

The putting on of these lines requires much training, and it is perhaps seen at its highest in the decoration one sees in perambulator, cycle, and locomotive work.

**Last Coat of Varnish.** After ref flattening we usually come to the final coat of varnish, which must flow freely under the tool, the use of a small tool in the other hand sometimes being considered a help in keeping an even surface. When a painter can put on the last coat successfully, he has reached the height of his profession. Clean tools in a dustless room free from draughts and maintained at a moderate temperature are necessary to the attainment of the beautiful and lustrous surface of a vehicle turned out by a good firm.

When one considers these coats—averaging 16 in number—and the time, some three or four weeks, for their application, he expects a very good result. This lengthy series of coats of paints applies, of course, only to the best work. The cheaper the work and the rougher the use for which it is intended, the less is the preparation. Vehicles that are finished in the natural colour of the wood generally receive one thin coat of linseed oil wiped off, six coats of gold size on panels, two or three coats of flattening varnish, finishing with one of best elastic varnish.

The quality of the varnish, especially in the final coats, determines to a great extent the permanency of the particular tint of body colour. We often see white made yellow, and blues given a greenish hue, while japan will take on a similar tint. Still, we must not always blame the varnish, for the colours themselves may be of indifferent composition and too fugitive to retain their original hues.

**Under-carriage Painting.** The under-carriage is often painted in a separate shop to the body, especially in large factories. It is painted much in the same way as the body, receiving a coat of lead colour or priming, which is sand-papered off when dry to receive another coat and consequent papering. The more open grain parts of the woodwork, such as are in the front of a compass bed and felloes, are filled with soft stopper, a thin plastering of dry white lead and turpentine. This, drying rapidly, is glass-papered off—a most unhealthy process for the workman; and it is far better for the usual body filling-up with the use of pumicestone and water to be adopted. We must take care not to fill up the carving on the under-carriage with the filling-up, and the less

filling used in this neighbourhood the better, for it is difficult to clean, and in attempting to do so the work is often destroyed. Afterwards we apply another coat of lead colour, and follow with two coats of ground colour, two of glaze or varnish colour, flattening as before with pumice-dust. The stock hoops, treads, and other black parts have two coats of japan and one flowing coat of best elastic varnish all over.

**Patent Wood Filling and Mechanical Painting.** As a substitute for the priming coats of lead colour, the "American method," or the Patent Wood Filling, is sometimes adopted. This filling is supplied in cans and is used either hot or cold, the former being preferable in cold weather. After applying the P.W.F., as it is abbreviated, the raised grain of the wood is removed with a piece of partly-used glass-paper. When this is completed, the P.W.F. is wiped off dry with pieces of cloth, sufficient having been left in the grain to answer the purpose. After this patent filling comes the application of the "rough stuff" or "filling-up" in the usual way.

The painting of passenger railway rolling stock is similar to that already described, except that fewer coats are used, and the whole process takes about 10 to 14 days. Seeing the large area of surface to be preserved by paint in a company's stock, it is not surprising to find mechanical methods adopted. By this means labour and cost are lessened, and paint may be applied quite as evenly as in hand work.

**Compressed Air in Painting.** Compressed air is the usual method by which a reservoir of paint placed on the ground is raised and forced through a sprayer at the end of flexible tubing. Both air and paint enter the nozzle of the sprayer, the paint being mixed a little thinner than usual, and passing through a small filter before it is formed into a fine spray by the current of air.

The tank is charged with air through a valve in the top until it indicates about 25 lb. to the square inch. The supply is disconnected, and the pressure thus formed will work the machine for some time. The supply of paint is under the complete control of the workman, and he can reach all corners and crevices. There is no outlay for tools, and if a separate can be kept for each colour—as is warranted in a large shop—much work will be saved in cleaning.

**Use of Sheet Metal.** The time taken by painting has, in America, led to covering the panels with thin sheets of metal, usually copper. It is, of course, more expensive in the first instance, but the little experience already gained tends to show that economy results, there being no repainting; and if damage should occur to a panel so protected, the metal will always find a good price as scrap.

**Choice of Colours.** In painting the rail waggons, road vans, and similar vehicles, we must remember that the material is not a very big item in proportion to the labour. Bright colours soon require renewal, but their use is often insisted on, for distinctive purposes such as refrigerator cars, or butter vans, while advertising demands a conspicuous pigment. The ends of railway stock are painted a darker colour, since, while travelling, they catch more of the smuts and dirt. The gentleman's carriage is, as a rule, painted in dark colours, according to the recognised canons of good taste. Sporting and self-driving vehicles have more showy undercarriages, being usually finished red or yellow. Motor-cars, at first violently coloured, are now following the custom set by the coachbuilder. Our London omnibuses under-carriages are in many instances painted yellow simply because they are thus rendered

interchangeable. Why yellow is used cannot be explained, unless it is to lighten the appearance of the whole.

Railway undergear and ironwork is generally painted black.

**Monograms and Heraldry Painting.** The highest branch of the vehicle painter's art is in the rendering of the various crests on the panels of the carriages of the nobility. A coronation involves much activity in this branch of the art.

Sometimes a painter who has used his spare time in studying heraldry, and has a natural artistic ability, puts on the crests required in the course of his business. The tendency nowadays is an increase in monograms [55, A, and C], which not only demand skill in execution, but also in designing the intertwining of the initial letters.

The coat-of-arms seen on railway and rolling stock, and the devices on motor omnibuses [55, B], are often put on by means of transfers.

55. VEHICLE MONOGRAM AND LINING WORK

A. Two-initial monogram. B. Trade mark, or badge, suitable for a motor omnibus company (Motto: "We must move with the times"). C. Three-initial monogram. D. Double line lining. E. Centering. F. Centering and double line lining. G. Edging. H, J, K, L, and M. Spoke face decoration

# BANKS AND INVESTMENTS

Management of a Banking Account. Penny Banks. General Advice to Investors. The Stock Exchange. Consols. Railway Stocks and Industrials

By C. DUNCAN CROSS

ONE of the great conveniences in life is a banking account. As an aid to account keeping it is invaluable, because from it large and small amounts can be paid by cheque; money can be sent safely by post, and the returned cheque acts as a receipt in case the payee's original receipt is lost. On the other hand, a banking account has its dangers, because it is so easy to draw a cheque where one would hesitate to pay over the actual money.

As to the choice of a bank, you must be guided largely by the state of your means. Most of the big banks insist upon a floating balance of not less than £50 for the private individual. Consequently, that £50 is lying idle, and you must keep an additional amount on which to draw. If the balance falls below that sum you are charged a varying sum per quarter—generally half a guinea—for the bank's trouble.

**Cheques.** Cheques are bills of exchange on the bank. They are of two kinds—*bearer* and *order*, of which the latter is infinitely preferable. The bearer cheque says: Pay Samuel Jones *or Bearer*. Either can present the cheque and receive money for it. It is quite possible, however, that the bearer may be some dishonest person, so the order cheque is to be preferred. It says: Pay Samuel Jones *or Order*. This means that Mr. Samuel Jones must sign the cheque himself before it is presented for payment. This, however, is not perfectly safe, because Mr. Jones's signature might be forged by some unscrupulous person who would receive his payment and make off before the fraud could be discovered; or Mr. Jones himself might sign the cheque and lose it, when the finder would obtain the money if he were quick. So, to make assurance doubly sure, we draw two lines across the face of the cheque, writing between them the words "and Co." These two transverse lines show that the money may only be paid by the bank named on the cheque to another bank, which in turn will place it to the credit of the payee. It cannot be cashed over the counter, so that it is safeguarded from the casual thief. Even now it is not perfectly safe, but since it is the form most used by business men in their dealings with one another, it is the form we recommend. If there is any cause to anticipate fraud or any need for special precautions, a cheque crossed with the name of the bank with which the payee has his account and the words "Not negotiable" is as secure as any cheque can ever be.

One further point about cheques still remains to be noted. We have already seen that endorsements may be forged and the money paid to a dishonest person; the banker is not liable if he has acted in good faith and without negligence.

But if the signature of the drawer is forged and the bank honours the cheque, then the bank is liable in nine hundred and ninety-nine cases out of a thousand; in the thousandth the fraud must have been assisted by gross negligence on the part of the man whose cheque has been forged.

**Pay-in Slips.** Payments are made on slips of paper called pay-in slips, and the bank keeps account of your spending and saving in a pass-book, on one page of which are kept all payments-in, and on the other all payments-out.

Certain banks, notably the Birkbeck, and some branch offices of the great banks, will accept an account with a much smaller floating balance than the £50 mentioned above. Small private banks in the country are being gradually driven out of existence or absorbed into the great joint stock banks. This is natural, for while a private bank may be excellently managed, the great limited company, with its enormous funds and its ample reserve as shown in its annual report, will always appeal to the man who likes to see the state of his bank's finances. It is an obvious fact, too, that a small bank cannot hope to give such good terms when, as is often the case, it does no more than act as middleman between a great bank and its clients.

For the smallest amount of savings there is an avenue in the penny banks. The National Penny Bank, Ltd., of London, is the senior of these, but there are many other smaller institutions of the kind scattered over the country. Their main principle is the same—that any amount from a penny upwards can be deposited. These amounts are pooled, and either paid into the trustees' account at the Post Office Savings Bank, or invested in trustee securities. There is, of course, no drawing account, as in the case of big banks; notice of withdrawal of part or whole of the deposits must be given in advance. In some cases the interest is paid to the depositors; in others it is used for working expenses. This is immaterial, for the great object of penny banks is to teach everyone the simplicity and importance of thrift.

**Investing.** Now we come to one of the most important parts of saving—namely, the investment of money, so that it may receive a higher rate of interest than is offered by the Post Office and at the same time increase in value if possible. Let it be understood that we deal here only in generalities, and that the general rules we offer are merely in regard to investing money and not for advising the speculator.

It is necessary first of all, in dealing on the Stock Exchange, to select a reputable firm of stockbrokers. Any good business man will

recommend a firm." Avoid being induced to deal with persons who advertise themselves and the wonderful "hauls" they have made for their clients. Generally they are harpies of the worst description, who will lead their unhappy client to speculate in the most extravagant "wild-cat" schemes. Not content with corrupting his morals, they rob him of his money by various ingenious methods. But enough of this for the moment.

**Bucket Shops.** Among the harpies which prey upon the gullibility of the public, the proprietor of the bucket shop is the worst. Dealings are carried on under what is known as the "cover" system—that is to say, the speculator is required to deposit with the bucket shop only a percentage—generally 1 per cent.—of the value of the stock in which he desires to deal, so that for an outlay of £5 he can deal in £500 of stock. If the stock immediately goes up one point he takes a profit of £5 and sells out. If, on the other hand, the stock falls a point the bucket shop sells his stock because his "cover" is exhausted and he loses the £5 at once, in spite of the fact that his stock may immediately after bound up several points.

Apart from the fact that the system is a gamble depending upon the capricious fluctuation of the market, the transaction becomes worse from the investor's point of view when it is known that in the vast majority of cases there is no purchase or sale of the stock by the bucket shop. Hence, it is obviously to the firm's interest that its client shall buy on a falling market, because in that case it pockets the "cover" without further trouble. This fact explains the anxiety of certain firms to advise the speculator in his dealings. It amounts to this—that the speculator is betting against the bucket shop, and, since the latter is a past master of the game in which he is a novice, he stands a poor chance of any permanent gain.

There are certain outside brokers who undertake this class of business also, and while they may be perfectly honest, the whole system of purchasing more than can be paid for is so fundamentally wrong that it need concern us no further.

Having selected your reputable broker, ask him to provide you with an official list of prices, or with one of the little books of selected securities which many brokers publish on their own account.

**The Risk of Big Dividends.** You must face the fact that if you want a high rate of interest for your money you must be willing to take a proportionate amount of risk. Up to 3½ per cent. the risk is very slight, but it is not so easy to get a safe investment at a much higher rate.

The reason for this is that if a concern or a corporation can offer ample security for money, it does not pay much for the risk of lending. On the other hand, if the risk is great, the investor will naturally ask for a high rate of interest.

So we see roughly what governs the rate of interest on stocks. A further question of great importance is the price at which you buy the

stock, and this is a very much broader issue. You will see in your Stock Exchange List that nearly every stock is either over or under *par*; that is to say, £100 worth of stock can be bought for less or more than its nominal value.

This means that the price of stocks is regulated by the law of supply and demand, and that if the public thinks well of the prospects of an investment the public does not object to pay more than the nominal value for it, either because it hopes for a greater rate of interest or, where the rate of interest is fixed as in debentures, believes the prosperity of the concern affords ample security. The price, of course, rises with the demand, and falls with a free supply.

It should be noted that the Stock Exchange List is a good index of the price only of large stocks. In smaller concerns, where there is little dealing, the actual price may differ considerably from the official price.

In the first rank of safe or "gilt-edged" securities are the stocks known as Trustee securities—namely, British funds and certain Colonial, corporation, or county stocks. That these are considered safe may be judged by the fact that the law allows trustees to invest other people's money in them. Now, since these stocks have a fixed rate of interest with good security, the point to be considered is the price at which they should be bought. What determines this? Let us take Consols as an example.

**Consols.** Putting aside the case of war or of national uneasiness in face of foreign complications, the price of Consols in peace time is regulated by the amount of money available for investment. If trade is booming, money will be required to develop it, to finance trade schemes and to pay wages. When money becomes scarce the reserves at the Bank of England sink, and people sell out their safe investments, because money is worth more than the 2½ per cent. which the Government is willing to pay for it. The price of Consols goes down, the price of the leading "gilt-edged" securities sinks, and there the price will stay until the value of money falls. For instance, trade slackens; less money is required in developing it; there is less turnover, fewer fresh schemes; less money is required for wages. Profits have been made in trade which must not lie idle; the Bank reserve fills up, and the demand for gilt-edged stock once more becomes so pressing as to raise the price.

So that trade is one of the most important factors in the gilt-edged security market. Trade comes in waves, with a hollow between the crests of prosperity, and no sooner has it reached its highest point than prosperity kills itself by causing over-production, and, consequently, depression.

**Railway Stock.** Another favourite avenue for investors is railway stock, in which, again, trade exercises a great influence. As trade improves, freight increases, and general traffic grows with it. Then expenses begin to rise, the cost of coal goes up, iron and steel go up, wages rise steadily, so that often the expenses in the wake of a trade boom will wipe out the extra profits. With the breaking

of the boom, the traffics subside and stocks fall rapidly unless kept up by outside considerations or the lack of other outlets for money. It is a question whether British railway stocks will ever again reach their highest point. Increased wages, shorter hours of work, and a higher standard of comfort in travelling are all causes which will militate against abnormal prosperity in the future.

The best sort of railway stocks for the investor are debenture or preference stocks of railways which are paying a good rate of interest on their ordinary stock. Ordinary stock, whose interest is dependent on the amount of surplus after paying the prior claims of the debenture or preference holders, is sensitive to every fluctuation, but a debenture stock carefully chosen can be locked away and the only trouble connected with it is the investing of the money it brings in.

Even the best of these debenture stocks fluctuate, of course, and the golden rule is to be in no hurry to invest. Place your money on deposit at the bank, which will pay you interest, and watch the markets for a little. You will find that there is often a high-water mark and a low-water mark in prices. When you feel that the low-water mark is approaching, step in. It is not possible to buy at the lowest price every time, but with judgment you may always avoid the highest. It is a golden rule for the investor to buy when trade in the particular direction has been stagnant for some time, and the lowness of the price is due to an exceptional condition of things, which in the ordinary course will disappear.

**Foreign Government Stock.** There is another, and rather less safe, market for those who insist on having a higher rate of interest—3½ per cent. is what you may have with safety in English securities, and 4 per cent. if you buy with great discretion and inside knowledge; 5 per cent. or more may be had from foreign Government stocks, but here the security is not so good. South American Governments and railways pay a very good percentage, but in these countries one must always face the possibilities of a revolution which will upset the existing state of things and send your stocks down. The day has passed when respectable republics default or refuse to meet their obligations, but there is the worry of the thing, the annoyance of having to wait for years before a recovery of prices, and the general feeling of insecurity which does not commend itself to the cautious investor. If you must go in for "foreigners," buy Government stocks or railway debentures well secured or guaranteed by Government. Above all things, do not buy when the particular country has been booming for any length of time. The boom is due probably to two or three years of good crops or two or three years' tranquillity. Five years of peace does not mean a settled country, and three good crops do not make an investor's paradise. It is only fair to say that some of the South American republics are becoming settled, and as prosperity increases the chances of revolt diminish.

Of other foreign markets the same is true. If you can take a wide view of the situation, can read your morning paper intelligently, you will be able whilst the money\* is accumulating to forecast what countries are in an unduly depressed condition, which in the ordinary course will right itself either by good crops, by industrial enterprise, or by freedom from internal troubles. These are the countries in which money should be invested.

"Industrials," or shares in industrial companies, are good for the investor who buys knowing the business and the people who are managing it. They are, however, most liable to fluctuations, and depend so entirely on the personality and business methods of the manager that they need to be very closely watched. As an additional disadvantage, they are in the majority of cases over-capitalised.

**Gold Mines.** Last of all in the list of money outlets come mines, and the best advice the investor can have is "Don't." A fortune may be made by investing money in a gold mine, but many thousand fortunes have been lost. To-day there may be more gold lying about than can be gathered up; to-morrow there may be nothing, and long, expensive borings may have to be made before any more gold is touched. Sometimes there never is any more gold. This risk has to be taken with the best managed and most trustworthy mines; but that is not the end of the trouble for the gold-mine investor. There has been more dishonest work in the form of engineers' reports about mines than in all the rest of the financial world together. A favourable telegram will send a mine booming in a day. A dishonest directorate spreads the report and sells its shares unostentatiously, and the next day the wire from the mine is not so hopeful. In a week the bubble has burst, and those who were inflating it gather up the shares at the bottom price to begin over again. There are other speculative markets of a like nature which need not concern the investor, whose only concern should be a fair amount of interest, and, if possible, a slight appreciation in value.

**Distribute Your Savings.** It is a good maxim in the case of foreign stocks never to put all the eggs into one basket, especially when the eggs, being few, are the more valuable. Most countries suffer from periods of depression at one time or another, but if one's investments are spread over a wide area these will be the less felt. With this idea, and exercising great caution in buying, we should be inclined to distribute a sum of £500 somewhat on this principle. The first £100, being a sort of reserve which might be wanted at short notice, should go into some gilt-edged stock. The next £100 might be invested in a railway debenture stock, the third in a mortgage, the fourth in a foreign Government bond, and the fifth in a foreign or Colonial railway debenture. £500 thus invested should bring in about £18 to £20 per annum. This works out at an average of nearly 5 per cent. on the amount invested, which is all that a prudent man should ask in the way of return for his investments.

# THE FATTY ACIDS

Soap and Saponification. The Food Value of Fat and its Explanation. Acids Derived from Fatty Acids

Group 5  
CHEMISTRY

24

ORGANIC CHEMISTRY  
continued from page  
3274

By Dr. C. W. SALEEBY

WE seem to have wandered far from the fatty acids, and it is like coming back to earth after an excursion into a "diviner air" to take up the tale at the point at which we left it before our quite inadequate reference to the genius who, as man, as citizen, as scientist, and as a friend of the human race, has very few peers and no superiors in history, and who must remain as a perfect type "to the last syllable of recorded time." But, as he himself was always saying, "Il faut travailler"—one must work.

**The Fatty Acids.** Two of the higher fatty acids must be mentioned because of the part which they play in the composition of certain very familiar and important natural products. These are *palmitic acid* and *stearic acid*. Together with a closely allied body, *oleic acid*, these form part of all natural fats and oils, whether vegetable or animal. Such fats and oils are, indeed, none other than salts, of which the base is provided by glycerine and the acid by the acids named. We now understand why this is known as the series of fatty acids. Palmitic acid has the formula  $C_{15}H_{31}COOH$ , and is most commonly prepared from palm oil. Its melting point is  $62^{\circ}C$ . At temperatures below this it is a white, waxy solid. Stearic acid is the next acid but one in the series, and therefore has the formula  $C_{17}H_{33}COOH$ . Its melting point is slightly higher, being about  $69^{\circ}C$ . Below this temperature its appearance is similar to that of palmitic acid. Its name is derived from the Greek *stear*, fat, and it forms the acid constituent of ordinary beef fat or suet.

**Saponification.** The higher fatty acids and oleic acid are commonly obtained in the course of the process which is called saponification. There is a great deal of complexity about the practice of this subject, but from the purely chemical point of view it is not so difficult to understand. We begin by assuming that a fat or oil consists of the glycerine or glyceryl salt of a fatty acid. If, now, this salt be decomposed by means of a powerful alkali, or by superheated steam, we shall obtain (1) the glycerine (as was seen when we were studying glycerine), and (2) the fatty acid—or rather a new salt formed by the union of the fatty acid and the alkali. This new salt is called a soap, and that is why the process is known as *saponification*. Let us now see whether this can be written out in a form which makes it memorable—not memorable in the sense that the reader can learn it off by heart, but in the sense that, having seen the principle of it, he can re-think it out for himself whenever required:

Glycerine—Fatty acid + Alkali = (Glycerine Fat

and Fatty acid-alkali (a salt called soap).

Similarly, superheated steam splits fats up into glycerine and the fatty acid, but we need concern ourselves no more with the acids in their acid form, and may now consider the salts which they form with alkalies, and which are called soaps.

**Soaps.** If we have a mixture of sodium salts of the three acids already named, it constitutes what we call a *hard soap*; if, on the other hand, the base be potassium, the physical state of the product is different, and we have a *soft soap*. In practice, soap is made by the process of saponification, fats being boiled with a strong solution of sodium hydrate; the products are, of course, soap, glycerine, and water. If, now, common salt or sodium chloride be added, the soap floats to the surface in an insoluble form, and can be removed when it cools. The very valuable glycerine is then recovered from the remainder.

As a rule, a commercial soap contains a varying quantity of free alkali, which adds greatly to its cleansing properties; on the other hand, the skin of a baby or the skin of the face of an adult—for instance—is intolerant of alkalies, and therefore one should employ what are called super-fatted soaps, which contain an excess of free fat. Many good soaps, also used for toilet purposes, contain free glycerine. In their manufacture, saponification is performed with an alcoholic solution of caustic soda; afterwards the alcohol is evaporated, the glycerine remaining intermixed with the soap.

The reader may ask whether it is possible to form fats by direct union of their constituents, just as salts in general may be formed by the union of acids and alkalies. It is possible, for the fats may be synthesised by raising to a high temperature a mixture of palmitic or stearic acid and glycerine. Later we shall see that the high temperature is not always necessary.

**Fats and Oils.** We cannot leave these very important substances, fats and oils, however, without further consideration. The reader is already aware that a fat is simply a solid fixed oil, and a fixed oil is simply a liquid fat. The word *fixed* has to be inserted because we must distinguish these oils from another series of bodies, of which an enormous number are known, and which, having a somewhat oily appearance, unfortunately have the same word applied to them. They are distinguished by being called *volatile* or *essential* oils; but even so it is a pity that one term is applied to two totally different kinds of substances, for the resemblance between the fixed and volatile oils begins and

ends with the solitary character of physical appearance. Whereas the fixed oils and fats are salts of the higher fatty acids and oleic acid, as we have seen, the volatile or essential oils have an entirely different constitution. For convenience we shall discuss them shortly; not because they have any relation whatever to the paraffins, but merely by way of pointing the contrast.

The *fixed* oils are so called because, unlike the volatile oils, they cannot be distilled without decomposition. Among the most important of their many solvents are ether and chloroform. They leave a greasy mark on paper, whereas the volatile oils do not.

**Fat in Physiology.** At the temperature of warm-blooded animals, such as ourselves, the fat of the body is semi-solid, so that it might just as well be called a fixed oil. For convenience, however, we shall simply use the word "fat" here. Our acquaintance with the chemical composition of fat is enough to show that it is capable of yielding a very large quantity of heat or other forms of energy when oxidised. Such oxidation does not occur on exposure of a fat to the atmosphere, even at the temperature of 98° or 100° F.; but it does occur at such a temperature within the body. As a matter of fact, fats are among the most valuable of all foodstuffs, especially in cold countries, owing to the large amount of heat which is produced by their oxidation within the body; hence the Eskimo lives mainly on blubber. Fat is an extremely bad conductor of heat, and hence its value as subcutaneous clothing. This novel phrase precisely expresses a most important function of fatty tissue. But for its thick coat of blubber, a warm-blooded mammal such as the whale could not possibly maintain its temperature in the Arctic Seas.

**The Digestion of Fats.** It is very remarkable and interesting that the process of saponification should have been performed daily in the animal body millions of years before it was discovered by chemists. Fat, having undergone no change in the stomach, is subjected to an alkaline medium in the bowel, and in this medium there is contained a small proportion of a ferment called *steapsin*, produced by the pancreas. This ferment, acting in the alkaline medium, splits up practically every molecule of the fat of the food into fatty acids and glycerine, and a certain amount of the fatty acids is neutralised, with the formation of *soap*. This soap is absorbed by the cells that line the wall of the bowel, and by their activity is again split up, and helps to form fat again within them. The unneutralised fatty acids and the glycerine are also taken up by the living cells, and are immediately recombined into fat at a temperature far below that necessary for the synthesis of fat from fatty acids and glycerine outside the body. Shortly after living cells of the bowel have been exposed to a mixture of fatty acids and glycerine, globules of fully formed fat or oil can be seen in their interior. Taking the average, it may be said that, of a total quantity of fat taken in the best physical form, which is that of an emulsion (the fat in milk, for instance, is emulsified), the bowel is found, only seven

hours later, to contain only 25 per cent. of neutral fat undecomposed, 72 per cent. of fatty acid and glycerine, and 3 per cent. of soap.

**Melting Points of Fats.** We may also briefly note that the food value of various fats or fixed oils is largely determined by their melting point. "The lower the melting point of the fat the more completely it is absorbed." The explanation of this, of course, is that a fat which is fluid at the body temperature is more easily taken up into the blood than one which remains more or less solid. The following, quoted from Hutchison's "Food and the Principles of Dietetics," are illustrative examples:

| Fat.          | Melting point. | Percentage unabsorbed. |
|---------------|----------------|------------------------|
| Butter .. ..  | 37° C          | 2½                     |
| Bacon .. ..   | 48° C          | 8                      |
| Mutton fat .. | 52° C          | 10                     |

**Cod-liver Oil.** There is one fat in particular which has a special interest for the chemist, because medical men tell him that its food value, in a thousand cases, is incomparably superior to that of any other fat except cream, and they ask for an explanation of this. Now, from the chemical point of view, cod-liver oil is extremely similar to any other fat. Eighty-five per cent. of it, for instance, is *olein*, which is the familiar fat compounded of glycerine and oleic acid, having the chemical name of *oleate of glyceryl* (glyceryl, we have seen, is the name applied to the group  $C_3H_7$ ). Ten per cent. more consists of *palmitin* and *stearin*. Plainly, there must be some other constituent which explains the peculiar value of this oil. The chemical explanation is that there is a certain proportion of *free* palmitic and stearic acid in cod-liver oil, and no less than 5 per cent. of *free* oleic acid.

**The Acids of Cod-liver Oil.** It is the presence of these free acids that makes the oil so valuable. They unite with the alkali in the bowel to form a soap which rapidly emulsifies the oil that constitutes 85 per cent. of the whole, and which, by emulsifying it, greatly facilitates its digestion and absorption. Hence, a mixture consisting of 6 per cent. of oleic acid and 94 per cent. of olein, is said to be as valuable as cod-liver oil itself. It is worth noting that better results follow the use of a rather dark-coloured and "tasty" cod-liver oil than the colourless, highly-purified, and almost tasteless oil which can now be obtained. The explanation of this seems to be that the more expensive oil has had a good deal of its free acid removed from it, and is thereby deprived of the possibility of that very rapid and easy absorption which makes dark cod-liver oil so valuable.

**The Volatile Oils.** Let us now discuss, simply by way of contrast, the volatile oils. They have nothing whatever to do with the others, having, indeed, no more in common than that they are hydrocarbons, and thus belong to the group from which the true oils are derived. The essential oils, as we know them, are mixtures of somewhat variable composition. They give plants their odours, and are largely used as

perfumes. Their function for the plant is not clearly known, though it is conceivable that they may act as protective antiseptics. The type member of their series is turpentine. Chemically considered, turpentine and many other volatile oils are composed of the bodies known as *terpenes*; the formula of which is in general  $C_{10}H_{16}$ .

**Properties of Volatile Oils.** The volatile oils are mostly inflammable, and lighter than water. They are very slightly soluble in water. They are usually prepared by distillation. We have, perhaps, somewhat exaggerated the uniformity of their composition, since many of them contain ethereal salts, alcohols, ketones, etc.; but terpenes are almost invariably present, and doubtless constitute the common ingredient which accounts for the very close and striking resemblance in the pharmacological behaviour which is exhibited by all the members of this group. In general, the volatile oils are apt to undergo oxidation on exposure to the atmosphere, and among the products of their oxidation are bodies known as *resins*. Various plants yield *oleo-resins*, which are natural solutions of resins in volatile oils. Very little is yet known chemically about terpenes, and their constitutional formulae are largely a matter of guesswork. The familiar substance known as *camphor* would appear, so far as its empirical formula is concerned, to be closely allied to these bodies, since that formula is  $C_{10}H_{16}O$ . It is an extremely interesting body chemically, since, while ordinary camphor is dextro-rotatory, a left-handed, or lævo-rotatory camphor is also known, as well as an optically inactive camphor. We may note, also, that the artificial synthesis of camphor is one of the very latest achievements of synthetic chemistry.

#### Acids Derived from Fatty Acids.

We must now note the existence of certain *substitution compounds* of the fatty acids. The name of these is legion, but we have space here merely to describe a few of them. There is a series of bodies which are derived from the fatty acids by the insertion of a hydroxyl group. On the one hand, these bodies are acids; but on the other hand, in virtue of their possession of one hydroxyl group, they are monohydric alcohols. The first of these *hydroxy-acids*, as they are sometimes called, is an extremely familiar acid, which we have often referred to ever since the beginning of our course. It is none other than carbonic acid itself. We have already seen that the term carbonic acid is often applied, for convenience, to the body which has the formula  $CO_2$ , and which should rather be called carbon dioxide, or, better still, carbonic anhydride, in order to indicate that it is the anhydride of an acid. The empirical formula for the acid is  $H_2CO_3$ , and we know that there is evidence for its existence as such. If we write its formula somewhat differently, new light is thrown upon its constitution. We shall write it thus:  $HO-CO-OH$ .

**Carbonic Acid.** This formula shows us, first of all, that carbonic acid obeys

the rule of which we have already spoken—that all the acids of carbon contain the carboxyl group  $COOH$ . Secondly, it shows us that carbonic acid is really none other than hydroxyformic acid. We know that the formula of formic acid is  $HCOOH$ , and plainly in carbonic acid the only difference is that a hydrogen atom has been replaced by hydroxyl. But this formula actually teaches us more, as the reader will be able to guess for himself if he draws it in its graphic form, placing the carbon atom in the centre, two of its hands being occupied with the atom of oxygen, and the other two with the oxygen atoms of the two hydroxyl groups respectively. Now, beside this formula, let the reader draw another, in which all the hydrogen atoms of methane have been replaced by hydroxyls. The difference between the two formulae will simply be equivalent to a molecule of water. In other words, carbonic acid, thus considered, is none other than the anhydride of orthocarbonic acid  $C(OH)_4$ .

**An Omission Repaired.** The critical reader will say that he has seen something like this before, and perhaps he will even recognise that we are now making good an omission which may have struck him. We have discussed the *monohydric alcohols*, have pointed out that two hydrogen atoms may be replaced by two hydroxyls, giving us *dihydric alcohols*, and that three hydrogen atoms may be replaced by three hydroxyls, giving us *trihydric alcohols*. There is surely no reason why we should stop here, and why there should not be *tetrahydric alcohols*, in which all the hydrogen atoms of methane are replaced by hydroxyls. Plainly, orthocarbonic acid is just such a tetrahydric alcohol. True, it is unknown; but we know its ethyl salt, and we know that it exists potentially. Let us now write out the two formulae and compare them:

The dotted line round the first of these graphic formulae encloses the constituents of water, and proves to us that carbonic acid is the anhydride of orthocarbonic acid. A few pages back we set the reader the task of drawing the graphic formula of the trihydric alcohol derived from methane, and of cutting out  $H_2O$  from it in such a way as to yield formic acid. If by any chance he found this task difficult, he will find it easy now that we have written out in full the identical process in the case of the tetrahydric alcohol. As the trihydric alcohol is related to formic acid, so the tetrahydric alcohol is related to carbonic acid. Again we see that there is a real simplicity underlying the apparent complexity of these compounds.

# THE ART OF WEAVING

Preparing Warp and Weft. Warping and Sizing Cotton, Wool, Linen, and Jute. Beaming the Web. Hand Loom and Power Loom

By W. S. MURPHY

THE primitive loom, still used in many parts of the world, is two sticks between which a row of single threads is stretched so as to be clear of the ground. Having wound a thread on a sharp-pointed and slender stick about the length of his finger, the weaver inserts the small stick up between the first pair of warp threads and down through the next pair, twining the thread with an alternate movement round every thread of the warp till he has brought it out at the other side. As has happened, the weaver may choose to pass his weft stick and yarn over two warp threads and under one, alternately or successively, or may vary the order in any way fancy dictates. This is weaving, and the most perfect machine contrived can do no more; in truth, some men with three sticks and an artistic soul have produced cloths which compare favourably with the best products of our power-driven, elaborately-contrived looms.

**Weft.** The yarn which forms the cloth by crossing the warp is *weft*. Sometimes it is called *filling*, because it fills up the spaces between the threads of warp. That portion of yarn set

apart as weft is wound on to pirns, or formed into cops, by any of the winding frames we have already considered. Though very important, the winding of wefts calls for no skill, unless it be the skill of the mechanic to see that the automatic machines are doing their work properly and to keep them in good order.

**Warp.** Because warp extends continuously throughout the whole length of the web and forms part of the loom, it is commonly looked upon as the backbone, the mainstay, the strength of the cloth. But the student must at once get rid of that notion; the warp may, as we have seen in our study of design, be the weakest and least valuable constituent of the cloth. Owing to causes which shall be shown, warp requires more elaborate treatment than weft; but the most valuable elements are not always those which give the most trouble.

Several kinds of cotton-warping machines have been invented and put into use. With threads so fine and slender, breakages are difficult to detect and prevent; but not one thread can be spared from the warp.

155. COTTON WARPING FRAMES (Horrockses, Crewdson & Co., Ltd., Preston)

**Cotton Warping Machines.** All the best warping mills are constructed so as to stop automatically when a single thread of the warp breaks. We take for study the warper originally invented by Singleton, of Darwen, and improved by later mechanists in various ways. It is a small machine [155]. Behind is set the bank, or reel, containing the bobbins of warp threads. Thence the threads are led through a comb or reed of vertical teeth, which separate the threads from each other and act as guides; further forward, the warp passes over a wide roller, under what are called the drop rollers, up over another roller, which guides the threads under the arches of little pendant wires which are kept in position by the support of the threads. Beyond is the warp beam, and upon it the warp is wound. We can watch the driving and stopping mechanism in motion better than by going over each part. At the bottom of the machine is a treadle; by pressing it, we bring the friction pulley into contact with the friction plate on the drum shaft, which starts the machine and calls the drop rollers into position. The warp moves through the machine like a broad stream of snow. Suddenly a thread gives way; down falls the wire, its lower end causing the rollers below, called *nip rollers*, to fall out of gear. The front nip roller bears with it the lever acting on the slide bar of the friction pulley, and sends it out of touch with the friction plate, stopping the machine. The drop roller has gone down and gathered up the slack of the warp, so keeping it regular and even.

The purpose of warping, as may be observed, is to make a certain length and number of threads lie evenly on a beam; this is the important point. The methods adopted may vary, as in forming chain warp [156], though the one given is the most common and quickest in the cotton trade.

**Warping Wool.** The old-fashioned warping mill of the woollen trade is a vertical reel, 20 ft. in circumference, formed of long rods fixed on spokes projecting from the central spindle like a gigantic lattice wheel. This reel is called a *two-string mill*, a string being 10 ft. in length. Newer reels are horizontal and may be two-string, three-string, or any fraction of that measure. Setting his yarn bobbins on the *bank*, as the tall frame for holding bobbins is called, the warper leads the threads through the eyelets of the guide pins, one above the other alternately, leaving an open space. Having determined the size of the bunches we want to make—it may be 30, 40, 50, or 60—we tie them together, and cross on the

top pins so as to form the length. Now set the reel in motion, and let it wind on the length of warp. This done, take the lease again; repeat the reeling till the whole warp is formed. When we have made the body of the warp, we reel enough of a strong yarn to make the *list*, or *selvedge*, which protects the sides of the cloth.

**A Modern Wool Warping Mill.** An ingenious horizontal warping mill [157] has lately come into use. The tension of the warp is apt to become irregular, and to obviate this a sectional dividing head has been devised. When the required number of bobbins have been placed on the reel, the thread is passed through the leasing-rod and reed, or heck, then through the patent dividing head, which is provided with an arrangement capable of being adjusted to the exact width of the section to be wound. As each successive layer of yarn is laid on the mill it is guided further up the incline. The first section being complete, by an ingenious arrangement the dividing head is moved the exact

width of the section. It is gauged so accurately that it is impossible to see where the sections are joined.

**Linen and Jute Warping.** The warping of linen and jute may be done either on the cotton or woollen warper. In actual practice we find that the cotton warper is more frequently used in the best linen factories, and the woollen mill is nearly always used in jute manufacture. But, having understood the principle of warping, the learner finds no difficulty in operating with any kind of warping mill.

156. CHAIN WARP

**Sizing.** When cloth was woven by hand, the operation we name *sizing* was called *dressing*. The sole object of the dressing in those simple days was to strengthen the warp for its labours in the loom. All the stress of tension, all the vibration of the weaving has to be borne by the warp, the weft suffering very little friction. It was found that, by coating the warp with a simple gluten, or starchy substance, such as may be made with water and flour, the threads were strengthened. When the machine factory system was introduced, this operation of dressing, or sizing, was found very troublesome, because it required to be done by hand, and numerous accidents constantly occurred to mar the efficiency of the work in the dressing-room. Hand sizing is done by the application to the warp of brushes containing a smear of the paste. This was the operation which was first made mechanical; but experience taught boldness, and sizing is now done, in all the

157. WOOL WARPING FRAME (W. Whiteley &amp; Sons, Ltd., Lockwood)

textile trades, by the immersion of the yarn in a bath, clearing and drying appliances being relied on to take away the superfluous size.

**Sizing Cotton.** Sizing is carried to the finest point of scientific application in the cotton trade. We may divide sizing into three grades: (1) *light sizing*, the object of which is to lay the fibres and give them coherence; (2) *medium sizing*, to add to the body of the fabric; (3) *heavy sizing*, to increase the weight, solidity, and density of the cloth. In sizing, we have to aim at three objects. First, we wish to make the threads of the warp hold firmly together, and for this purpose use any kind of starchy substance, such as wheat flour, farina, rice flour, sago, or maize, finely disintegrated, so as to enter the body of the yarn; secondly, the yarn should be softened and made smooth by mixing into the size any suitable vegetable oil or animal fat; and, thirdly, the size must be prevented from rotting the yarn, and an antiseptic should be put into the mixture for that purpose. We give the principles of sizing only, because every manufacturer has his own recipe for the mixture. China clay is almost the universal medium of loading, or heavy sizing.

In the sizing bath itself, we find nothing new; it is a vat containing hot size, equipped with rollers to guide and dip the warp threads well into the liquid. But the main trouble which the warp dresser has always encountered occurs in the drying of the sized warps.

Mildew, inequality of texture, and other minor evils, may attend the operation of sizing, and the object of the machinist has been to make a sizing machine which would obviate these evils satisfactorily. Steam-heated cylinders, hot-air chambers, and cold air, have been adopted, and used in several ways. In the first, which is the oldest, the warp passes from the size trough through the flannel-covered clearing rollers round two steam-heated cylinders, sheathed in copper or brass, thence passing into the teeth of the reed, and round the beam again. Hot-air sizing machines substitute the hot-air chambers for the cylinders, the air being drawn through hollow chambers over steam tubes. In the management of these sizing and drying machines [158] much practical skill and watchful care must be exercised.

**Wool Sizing.** The sizing of woollen warps is dressing in its purest form. The sole object is to make the threads smooth, strong, and easy to work. But the yarn is of such an open structure that we must apply the size firmly and liberally, yet with judgment, to get good results. This sizing machine differs in some important particulars from that of the cotton manufacturer. When the wool issues from the size bath, it passes between the clearing rollers, through brushes that gently smooth off the size, round the steam-heated drying cylinder, and through the comb on to the warp beam.

The main constituents of the

158. SIZING MACHINE (Atherton Bros., Preston)

159. WARP BEAMING (H. Bannerman &amp; Sons, Ltd., Manchester)

size are flour and water, though some use a thin glue made from rabbit skins. Good dressing and efficient machines are very important to the woollen manufacturer.

**Linen Sizing.** Irish moss is largely used in the making of linen size. It is a seaweed growing abundantly on the west and north-west coast of Ireland, in parts of the western coasts of Europe, and on the eastern seaboard of America.

In many linen factories, sizing and beaming are done in one operation. One of the finest of the machines for the purpose is what may be described as a *double dressing machine*, though it produces only one warp in the operation. As it includes most of the best features of the newest contrivances of its class, we shall give close attention to the structure and mode of working.

In the centre of the machine the weaving beam is hung, with an expanding roller resting upon it. On each side of it are the drying steam chests; further along are the clearing brush rollers; further still, the troughs of size, and beyond, at both ends, a pair of warp rollers. From the warp banks the threads are led in through guides, down round the roller running in the trough, up between the pressing rollers, through among the hairs of the revolving

brushes, over the drying chests, and up on to the weaving beam. Thus a warp of linen is at once sized and beamed.

**Jute Sizing.** Jute differs from almost any other textile fibre in that it is much used in the *green* or unsized state. The fine spun yarns however, which those who desire the advancement of the fibre favour, are sized on a very simple sizing and beaming machine, something like a single side of the linen machine described above. The size most commonly used is a thin farina paste.

**Beaming.** In most classes of cloth manufacture, beaming is a simple process [159]. As we have shown, beaming may be combined with dressing or sizing. It would be a mistake, however, to suppose that beaming requires no practical skill or no selection of machines. There are good beamers, good machines, and machines inefficient. Generically, beaming is the passing of a warp or warps through a regulating series of vertical pins, variously named the *reed*, *herk*, *wraith*, or *raddle*, on to a weaving beam. But in that simple act there are difficulties to be overcome and errors to be avoided. For example, if a part of the warp becomes slack through any cause the weaver's work is spoiled. Tension, equal and regular, is one of the most important requirements in beaming, and it is not always easy to secure. Threads may break, and in that case a hole will appear or a lost thread will run through a large part of a web. The beamer must exercise great watchfulness. On some beaming machines the wire stop-motion is set; but on others the beamer has to depend on his own eye. Coloured warps, for stripes and checks, call for care and watchful control. To become an efficient beamer is to be a skilled workman. Observe the perfect regularity of the threads on the beam [160].

160. BEAMED COTTON

**The Hand Loom.** Before we can understand the power loom and its numerous complicated mountings; we must know the hand loom thoroughly. Many modern looms have almost lost their character as looms, and have become what one might properly call cloth-making machines. We do not purpose going into the history of the loom, but intend to study the hand loom [161] as it is at present in use. For it should be clearly understood that the hand loom weaver still plies his trade, even in London, the heart of modern civilisation. Hand looms are used in the best factories for the testing of new patterns. The loom is supported on four posts; heavy looms have six posts, for reasons which we shall see. Between the two fore posts the cloth beam is supported in a bracket which allows it to turn freely on its own axis. On the end of the beam is a plate with toothed edge,

into which a strong clutch grips. Along the heads of the supporting posts runs a strong framing, and from this depends the *batten* or *slay* or *lay*, as it is variously called. Two flat pieces of wood depend vertically from a cross beam moving easily on the frame above, and on their ends is fixed the slay, which holds the shuttle boxes and the reed, and forms the shuttle race. On each end of the slay is a shuttle box. It is rather more than a foot long, and along its centre is a steel spindle, securely fastened at both ends, and above the level of the shuttle. On this spindle sits the *picker*, a Y-shaped piece of wood, or hard leather, and

cords are run through its heads along to a handle in the middle of the loom. Keeping our eyes meanwhile on the slay, we note, under the strong head extending from one shuttle box to the other, a series of vertical wires embedded in two horizontal laths. This is the reed, whose double function is to let through the warp and press home the weft. The flanged ledge below the reed is the shuttle race. Behind the slay hang two or more healds. A heald is composed of two slats of wood, held together by closely set cords, about 10 in. long, between the shafts; the cords are vertical and the shafts horizontal. In the middle of each cord is a little eyelet, generally of brass. The healds hang from the loom frame, and cords extend from the ends of the healds to treadles below the loom. At the back of all sits the warp beam, with weights at each side to regulate the delivery of the warp.

**Warp and Weft in Hand Loom.** We return to look more closely into the loom. The warp passes through the eyelets in the healds in a certain order. For simplicity, let us suppose this a plain loom with two healds.

Every alternate thread passes through the eyelets of one heald, and the other half of the warp passes in like manner through the second heald. If the first heald can be depressed while the second remains stationary, the warp will be opened up into two halves with a space between. That is precisely what the depression of one of the treadles is designed to do, and the opening caused is called the *shed*. Having got our warp, we now demand the weft. This is supplied by the shuttle, a piece of wood, tipped at both ends with iron, hollowed out to hold the pirn or cop, with an eyelet pierced on each side near the tip to let the thread through. Fix in the weft pirn, suck the thread through the shuttle eye, twine it in the selvedge warp, shove the shuttle into the shuttle box on the slay, pushing the picker back along its spindle, and make ready to begin. Take hold of the handle, from the wings on the head

of which extend the cords to drive the pickers on both sides; grasp with the left hand the head of the slay; put your feet on the treadles. With the right foot depress the treadle, and see the warp making a shed by the depression of the heald; give the handle a quick jerk to the left, and the picker strikes the shuttle a firm blow, sending it flying across the loom, through the shed, leaving along its course a line of weft; draw the slay forward and drive home the weft thread; you have woven a pick. By depressing the second heald with the left foot, you cross the warp over the weft, and by bringing back the shuttle with a

stroke of the handle from left to right, you put in another pick. Weaving is nothing more than a continued repetition of these actions.

**The Power Loom.** So large a part does the human factor play in weaving with the hand loom, that the possibility of employing automatic machinery for cloth manufacture seemed very remote for a long time. Hands, feet, body, and brain are actively employed by the weaver on his loom. The history of the development of the power loom reads like a romance; but this is not the place for the story. In all the histories, the Rev. Edmund Cartwright figures as the first inventor of this wonderful machine, though later investigations have brought the claims of other men forward for share in the honour. Keeping to our method of proceeding from the simple to the complex, we shall examine a plain power loom [162], and afterwards study some of the more important additions and improvements.

**A Plain Loom.** Instead of presenting its working parts to the outward view, like the hand loom, this loom has most of its working parts inside. A strong iron frame contains the loom.

161. A MODERN HAND LOOM  
(H. Bannerman & Sons, Ltd., Manchester)

Through the centre extends the driving shaft, its bearings in the sides of the frame, and projecting out to take on the driving and loose pulleys. On the shaft are the cranks which control the movements of the slay, the latter being held on the rocking rail, and supported by slay swords, projecting upward from the bottom of the loom. Attached to the slay sword is a pin working in a slotted lever, a catch from which actuates the ratchet wheel, connected with the change wheel acting directly on the wheel on the end of the roller above the cloth-beam. The roller is borne down on the cloth-beam by weights, and turns it by friction. This means that the cloth-beam will take up just in proportion to the number of picks we may determine. The actuating wheel is a change wheel, and may have any number of teeth from

20 to 70. If a thin distribution of weft is desired, a quick-change wheel is put on; if the weft is to be close and firm, the wheel with the fewest teeth is put on. In structure, the slay of the plain loom differs little from that of the hand loom. We have seen how the slay and cloth-beam are actuated, but cloth could not be woven by these alone. Below the main shaft, and deriving power from it by a pinion wheel, is another shaft which has for its share of the labour the driving of the pickers and healds. First, on the shaft, just inside the frame at both sides, are the picking cones, their points set opposite to each

other, so that they will strike alternately. From the head of the loom the vertical shafts on which the picking arms are fixed descend, a bowl on the end of each. When the cone strikes the bowl it causes the shaft to turn half round. A leather thong connects the picking arm with the picker at the end of the shuttle box. When at rest, the picking arm is just in position for a stroke. At the sharp stroke of the cone on the shaft below, the picking shaft turns round, directing the arm which strikes the picker and drives the shuttle. This shaft has still another duty to perform; besides driving the shuttle, it also moves the healds. On a boss in the centre of the shaft two eccentrics are fixed which alternately depress two levers. In the

treadle grate the ends of the levers work up and down, while their heads are held by a rod fixed in the hinder end of the frame. At the back of the loom sits the warp beam, and in front of it is the carrier roller. Between the carrier roller and the slay is a space bridged over by the heald shaft. On this the healds are hung, the lower shafts being connected with the treadles. At the side of the loom is the small projecting lever which puts the pulley in or out of gear.

**Improvements.** A careful study of the parts of this loom reveals several points where development could begin and where mobility could be given to the mechanism. The starting lever gives a hint which mechanics were not slow to accept, and now, on most looms, the automatic

162. ORDINARY POWER LOOM (Atherton Bros., Preston)

stop-motion fork is fitted. Through a grating in the slay, between the end of the shuttle box and the reed, comes a hook, always lifted up by the weft from the shuttle. When the weft breaks, the fork remains fixed and acts upon a lever, which in turn acts on the starting spring lever we have mentioned. The shuttle box has also been reformed. The drop box was a part of the hand loom, but the power loom mechanics made six drop boxes, and then resorted to a revolving shuttle box. The boxes are brought into position by a simple arrangement of spring levers, which can be set to bring the required shuttles up at the proper moment. In this way many wefts of different colours can be woven at once.

### VERBS

#### Conjugation of Ser, To be

| INFINITIVE | GERUND        | PAST PARTICIPLE |
|------------|---------------|-----------------|
| ser, to be | siendo, being | sido, been      |

#### INDICATIVE MOOD

| Present        | Imperfect       |
|----------------|-----------------|
| soy, I am      | era, I was      |
| eres, thou art | eras, thou wast |
| es, he is      | era, he was     |
| somos, we are  | éramos, we were |
| sois, you are  | erais, you were |
| son, they are  | eran, they were |

| Past Definite      |
|--------------------|
| fuí, I was         |
| fuiste, thou wast  |
| fué, he was        |
| fuimos, we were    |
| fuisteis, you were |
| fueron, they were  |

#### CONDITIONAL MOOD

|                         |
|-------------------------|
| sería, I should be      |
| serías, thou wouldst be |
| sería, he would be      |
| seríamos, we should be  |
| seríais, you would be   |
| serían, they would be   |

| Future               |
|----------------------|
| seré, I shall be     |
| serás, thou wilt be  |
| será, he will be     |
| seremos, we shall be |
| seréis, you will be  |
| serán, they will be  |

#### IMPERATIVE MOOD

|                   |
|-------------------|
| se, be (thou)     |
| sea, let him be   |
| seamos, let us be |
| sed, be (you)     |
| sean, let them be |

#### SUBJUNCTIVE MOOD

##### Present

|                     |                   |
|---------------------|-------------------|
| sea, I may be       | seamos, we may be |
| seas, thou mayst be | seáis, you may be |
| sea, he may be      | sean, they may be |

##### Imperfect

|                                    |
|------------------------------------|
| fuera, or fuese, I might be        |
| fueras, or fueses, thou mightst be |
| fuera, or fuese, he might be       |
| fuéramos, or fuésemos, we might be |
| fuerais, or fuerais, you might be  |
| fueran, or fuesen, they might be   |

##### Future

|                            |
|----------------------------|
| fuere, when I shall be     |
| fueres, when thou wilt be  |
| fuere, when he will be     |
| fuéremos, when we shall be |
| fuéreis, when you will be  |
| fueren, when they will be  |

The compound tenses are formed by adding the past participle *sido* (been) to the verb *haber*.

|                                |
|--------------------------------|
| he sido, I have been           |
| has sido, thou hast been       |
| ha sido, he has been           |
| hemos sido, we have been       |
| habéis sido, you have been     |
| han sido, they have been, etc. |

**Tener.** To have. The verb *tener*, as already explained, regularly represents *to have* as a principal verb, signifying possession; nevertheless, it is constantly used instead of the auxiliary verb *haber*. For instance, the phrase "I have bought many houses" may be correctly rendered *He comprado muchas casas*, or, *Tengo compradas muchas casas*, the only difference being that the participle *comprado* (bought) is variable when used with *tener*, and invariable with *haber*.

*Tener* is also used idiomatically in Spanish in many cases where the verb *to be* would be used in English.

Examples:

|   |
|---|
| tener frío, to be cold (literally to have cold) |
| tener hambre, to be hungry                      |
| tener sed, to be thirsty                        |
| tener razón, to be right                        |
| tener culpa, to be in fault                     |
| tener miedo, to be afraid                       |
| tener edad, to be old                           |
| tener lástima, to be sorry                      |
| tener vergüenza, to be ashamed, etc.            |

#### Conjugation of Tener, To have

| INFINITIVE | GERUND |
|------------|--------|
|------------|--------|

|                |                  |
|----------------|------------------|
| tener, to have | teniendo, having |
|----------------|------------------|

#### PAST PARTICIPLE

|             |
|-------------|
| tenido, had |
|-------------|

#### INDICATIVE MOOD

| Present          | Imperfect          |
|------------------|--------------------|
| tengo, I have    | tenía, I had       |
| tiene, thou hast | tenías, thou hadst |
| tiene, he has    | tenía, he had      |
| tenemos, we have | teníamos, we had   |
| teneis, you had  | teníais, you had   |
| tienen, they had | tenían, they had   |

#### Past Definite

|                     |
|---------------------|
| tuve, I had         |
| tuviste, thou hadst |
| tuvo, he had        |
| tuvimos, we had     |
| tuvisteis, you had  |
| tuvieron, they had  |

#### Future

|                          |
|--------------------------|
| tendré, I shall have     |
| tendrás, thou wilt have  |
| tendrá, he will have     |
| tendremos, we shall have |
| tendréis, you will have  |
| tendrán, they will have  |

#### CONDITIONAL MOOD

|                             |
|-----------------------------|
| tendría, I should have      |
| tendrías, thou wouldst have |
| tendría, he would have      |
| tendríamos, we should have  |
| tendríais, you would have   |
| tendrían, they would have   |

IMPERATIVE

KEY TO EXERCISE X. (2)

1. After having eaten we went for a walk.  
2. To have sung, and to be crying.  
3. I am seated with my hat and overcoat on.  
4. I have been charitable; I have given bread to the children.  
5. I had gone out with my dog, the collegian being at home.  
6. I shall have to have a horse; you will have to buy a mule.  
7. We have to inherit much money.  
8. We have killed the thief.

PROSE EXTRACT IX.

From "La Armada Invencible," by Cesario Fernandez Duro.

As in historical studies small points as well as great should be cleared up, it will not be idle to examine the justice of the charges of vanity and arrogance brought against us in epigrams by some, on account of the exaggerated adjective of "invincible" applied to the Armada.

The documents given in this work show with what seriousness the King of Spain prepared the expedition, firmly resolved to obtain satisfaction for the injuries he had received, but with the nobility of the strong and the clear conscience of one who has first exhausted all means of conciliation. In the orders, instructions and letters there is no haughtiness of language nor presumption as to the issue; the strength of the enemy is not decried nor his own extolled. Philip considers their condition, practice and

Porque en los estudios historicos lo pequeño como lo grande debe esclarecerse, no es ocioso investigar la razon de los cargos de vanidad y arrogancia que con epigramas nos han hecho algunos por el adjetivo hiperbólico de *invencible* aplicado á la Armada.

Los documentos que acompañan al presente escrito muestran la seriedad con que el Rey de España preparó la expedición, firmemente resuelto á satisfacerse de las injurias que habia recibido, pero con la nobleza del fuerte y la conciencia del que ántes ha agotado los medios de conciliación. En las órdenes, instrucciones y cartas no hay altivez en la frase ni presunción en el éxito; ni se desprecia la fuerza del enemigo, ni se encomia la propia. D. Felipe las considera en condiciones, en práctica,

relative dispositions, as the soldier and politician must always consider them, calmly calculates the strategy and risk required to make his own strength superior, and having completed his plan to his own satisfaction, commits the result to the hands of God, "Who giveth or withholdeth victories at His will." The word *invincible* certainly did not originate with the king, nor, consequently, with any of his servants, including the Duke Alonso de Guzman, who, if he did not measure his words so much, was nevertheless not ignorant of the rules of courtesy. This word is not used in his despatches either.

It is possible that it may have been used in familiar conversation by the young men who sought fame in the conflict; but if this were so, the slight grounds of such a popular origin does not authorise formal censure. Not one of the Spanish chroniclers of that time, and they were not few, alludes to the force assembled at Lisbon by any other name than "the Armada," or "the great Armada"; it is thus designated by many foreigners, and if a report was printed in Lisbon giving it the title of "the most for-

en disposición relativa, como el político y el militar han de considerar las siempre, calcula á sangre fría la cifra y la ocasión con que la suya alcance superioridad, y terminado á satisfacción el plan, pone el efecto en manos de Dios, "Que dá y quita las victorias como quiere." La palabra *invencible* no procede, con toda seguridad, del Rey, ni de ninguno de sus servidores por consiguiente, incluso el D. Alonso de Guzman, he que, si no media tanto las suyas, no dejaba, sin embargo, de conocer las reglas de la cortesía. En sus documentos tampoco la usó.

Posible es que entre la gente joven que buscaba la fama en la contienda, se pronunciase en la conversación familiar; si así aconteció, la procedencia vulgar no autoriza á formular censura sobre base tan débil. Ninguno de los cronistas españoles de la época, y no son pocos, nombra á la fuerza reunida en Lisboa de otro modo que "la Armada" ó "la grande Armada"; así la designan muchos extranjeros, y si en Lisboa se imprimió relación que la titula "felicísima Armada,"

fortunate Armada" because the fleet of D. Alonso de Bazan was formerly so called, it is still only a popular title, nor is "fortunate" synonymous with invincible, though the second adjective may also be somewhat presumptuous.

In Flanders, where Catholics and Lutherans were fighting with the fury peculiar to civil warfare, the former struck certain medals alluding to the Armada, of which their opponents were to feel the effect, and it may be that these artistic manifestations, to which no one has given a thought, though they must have been very galling to the people of Holland and Zealand at the time, may have given rise to the expression which the sarcasm of the English so unjustly casts up at us.

Cesareo Fernandez Duro (1830—) a retired naval officer and eminent naval historian, the author of an exhaustive history of the Spanish Navy from the time of the union of the kingdoms of Castile and Aragon. In the "Invincible Armada" he has published with critical notes and comments all the contemporary documents and official despatches concerning the expedition of the Spanish Armada.

porque así se designó antes á la de D. Alonso de Bazan, ni dejó de ser vulgar la aplicación, ni es lo mismo que invencible, dichosa, siquiera haya algo también de presunción en el segundo adjetivo.

En Flándes, donde católicos y luteranos luchaban con la saña peculiar de las guerras intestinas, grabaron los primeros unas medallas alusivas á la Armada, por cuanto habían de sentir su efecto los contrarios, y acaso fueran las manifestaciones artísticas, en que nadie ha pensado, aunque debieron mortificar mucho por entonces á los de Holanda y Zelanda, motivo de la expresión que el sarcasmo de los ingleses nos devuelve tan injustamente.

Cesareo Fernandez Duro (1830—) un oficial de marina retirado y historiador eminente, autor de una inviolable historia de la marina española desde el tiempo de la unión de los dos reinos de Castilla y Aragon. En la "Armada Invencible" publicó con notas y comentarios críticos todos los documentos contemporáneos y despachos oficiales concerniente la expedición de la Armada española.

### IRREGULAR VERBS

#### First Conjugation

The first conjugation has four irregular verbs: *andare* (ahn-dah-reh), to go; *fare* (fah-reh), to do, to make; *dare* (dah-reh), to give; *stare* (stah-reh), to stand, to stay.

These four verbs are very common, and should be learned by heart.

#### Andare, to go

Stems *and* and *vad* (from an unused *vadere*).

Present Ind.: *vo* and *vado*, *vai*, *va*, *andiamo*, *andate*, *vanno*.

## By Francesco de Feo

Imperfect: *andavo*, *andavi*, *andava*, *andavamo*, etc.

Past Def.: *andai*, *andasti*, *andò*, *andammo*, etc.

Future: *andrò* (*anderò*), *andrai* (*anderai*), etc.

Imperat.: *va* (*vai*, familiar), *vada*, *andiamo* *andate*, *vadano*.

Pres. Subj.: *vada*, *vada*, *vada*, *andiamo*, *andiate*, *vadano*.

Imp. Subj.: *andassi*, *andassi*, *andasse*, *andassimo* etc.

Conditional: *andrei* (*anderei*), etc.

Gerund: *andando* (going).

Past Part. : *andato*, -a, -i, -e.

NOTE. *Riandare*, when meaning to reconsider, is regular.

**Fare**, to do, to make

(Contracted from the old *facere*. Second Conj.)

Present Ind. : *fo* and *faccio*, *fai*, *fa*, *facciamo*, *fate*, *fanno*.

Imperfect : *facevo*, *facevi*, *faceva*, *facevamo*, etc.

Past Def. : *fecì*, *facesti*, *fece*, *faccemmo*, *faceste*. *fècero* (poet. : *fei*, *festi*, *fe'*, *femmo*, *feste*, *fero*).

Future : *farò*, *farai*, *farà*, *faremo*, etc.

Imperat. : *fa* (*fa'*, *fai*, familiar), *faccia*. *facciamo*, *fate*, *facciano*.

Pres. Subj. : *faccia*, *faccia*, *faccia*, *facciamo*, *facciate*, *facciano*.

Imp. Subj. : *faceSSI*, *faceSSI*, *faceSse*, *faceSSimo*, etc.

Condit. : *farei*, *faresti*, etc.

Gerund. : *facendo* (doing, making).

Past Part. : *fatto*, -a, -i, -e.

The compounds of *fare* are conjugated in the same way. The commonest are :

*disfare* (*dees-fàhreh*), to undo,

*soddisfare* (*soddees-fàhreh*), to satisfy,

*contraffare* (*contrahfjàhreh*), to counterfeit.

**Dare**, to give

Pres. Ind. : *do*, *dai*, *dà*, *diamo*, *date*, *danno*.

Imperf. : *davo*, *davi*, *dava*, *davamo*, *davate*, *davano*.

Past Def. : *diedi* and *dètti*, *desti*, *diede* and *dette* (*diè*), *demmo*, *deste*, *dièdero* and *dèttero* (poet, *diero*).

Future : *darò*, *darai*, *darà*, *daremo*, etc.

Imperat. : *da'*, *dia*, *diamo*, *date*, *diano*.

Pres. Subj. : *dia*, *dia*, *dia*, *diamo*, *diate*, *diano*.

Imp. Subj. : *dèssi*, *dèssi*, *dèssi*, *dèssimo*, *dèste*, *dèssero*.

Condit. : *darei*, *daresti*, etc.

Gerund. : *dando* (giving).

Past Part. : *dato*, -a, -i, -e.

NOTE. *Ridare*, to give back, is conjugated like *dare* : Pres. Ind. : *ridò*, *ridai*, *ridà*, etc. Verbs ending in *-dare* are regular, as : *comandàre*, to command ; *circondàre*, to surround ; *assessondàre*, to second.

**Stare**, to stand, to stay

Pres. Indicat. : *sto*, *stai*, *sta*, *stiamo*, *state*, *stanno*.

Imperf. : *stavo*, *stavi*, *stava*, etc.

Past Def. : *stètti*, *stèsti*, *stette*, *stemmo*, *stèste*, *stèttero*.

Future : *starò*, *starai*, *starà*, etc.

Imperat. : *sta* (*sta'*, *stai*, fam), *stia*, etc.

Pres. Subj. : *stia*, *stia*, *stia*, *stiamo*, *stiate*, *stiano*.

Imp. Subj. : *stessi*, *stessi*, *stesse*, *stéssimo*, etc.

Condit. : *starei*, *staresti*, etc.

Gerund. : *stando* (staying).

Past Part. : *stato*, -a, -i, -e (stayed).

Verbs ending in *-stare* are regular, as : *restare*, to remain ; *contrastare*, to dispute.

NOTE. *Contrastare*, when meaning to oppose, is conjugated like *stare*.

The following verbs are also conjugated like *stare* : *riutare*, to cease ; *sottostare*, to be beneath ; *sovrastare* (in some forms also reg.), to be above.

The English forms *I am*, etc., *I was*, etc., followed by the present participle of the verb, are rendered in Italian by the present and imperfect. These forms may also be rendered by the present and imperfect of the verb *stare*, followed by the gerund. Examples : *I am speaking*, *parlo*, *sto parlando*. *I was reading*, *leggevo*, *stavo leggendo*. *He is thinking*, *pensa*, *sta pensando*. *They were working*, *lavoravano*, *stavano lavorando*.

## EXERCISE XXI.

Shall we go ? Let us go. Let us not go. We shall not go. They went. We went. I gave. I shall not give. Will you do it ? I am doing it. Are they doing it ? Will they not give ? Is he staying ? He will not stay. Did you go ? I have gone. If I gave. Would he not give ? They would not do it ? Shall I not go ? You did not go. They would have gone. If I had not gone.

## ESERCIZIO DI LETTURA

Un certo astrologo (1) annunziò un giorno la morte di una signora, molto cara a Luigi Decimo-primo. Poco tempo dopo (2) la predizione (3) questa signora infatti cessò di vivere (4). Il Re restò addoloratissimo ed essendo molto superstizioso, pensò subito che la predizione fosse stata la causa di quella morte immatura. Egli decise (5) quindi di far mettere (6) a morte il malaugurato astrologo e comandò che fosse arrestato e portato subito alla sua presenza (7). Quando lo (8) vide (9), il Re l'accusò di esser stato la causa di quella morte e l'invitò a parlare in sua difesa. "Magnanimo Re,, rispose l'astrologo senza esitare "io non ho niente da dire in mia difesa, perchè la mia predizione era segnata a caratteri indelebili nel corso delle stelle (10), ed è mia virtù di poter predire i destini (11) degli uomini,,. Irritato il Re di tale risposta, disse : "Ebbene, giacchè (12) tu pretendi (13) di essere tanto sapiente da conoscere (14) i destini degli uomini, dimmi (15) quale sarà il tuo destino,,. L'astrologo indovinò il significato (16) delle parole del Re, e rispose (17) subito : "Sire, io prevedo che cesserò di vivere tre giorni prima di Vostra Maestà,,. Il Re ammirò la furberia dell'astrologo e, anche per un po' di paura, invece (18) di farlo mettere a morte, ordinò che si pensasse al suo mantenimento, sperando in cuor (19) suo che si conservasse in ottima salute (20) ancora per moltissimi anni.

NOTES. 1. Astrologer. 2. After. 3. Prediction. 4. To live. 5. Decided. 6. To put. 7. Presence. 8. Him. 9. Saw. 10. Stars. 11. Fate. 12. Since. 13. Pretendere, to pretend. 14. To know. 15. Tell me. 16. Meaning. 17. Answered. 18. Instead. 19. Heart. 20. Health.

## CONVERSAZIONE

Che cosa cercate ? (What are you looking for ?)

Cerco i biglietti ; non so più dove li ho messi.

Li (them) ho io, andiamo ; è già molto tardi.

Credete che arriveremo in tempo ? Prendiamo una carrozza.

A che ora saremo a Roma ?

Domani alle tredici, credo.  
Avete scritto (written) che preparassero delle stanze?

Scrissi (I wrote) una lettera l'altra settimana e ho mandato un telegramma stamattina.

Credete che il signor Giorgio sarà alla stazione al nostro arrivo?

Certamente, egli penserà a tutto.

Sono molto contenta di essere in treno, amo molto viaggiare.

Anch' io (so do I), viaggierei sempre.

Quanto tempo ci fermiamo qui?

Cinque minuti, signora.

Gràzie. Non abbiamo tempo di mangiare.

Tanto meglio, non ho ancora appetito; mangeremo alla prossima stazione.

#### EXERCISE XXII.

1. We are going to the theatre this evening.  
2. Where are you going? 3. What shall we do to-morrow? 4. I am going into the country.  
5. We will go and (a) see the new church. 6. What are you doing? 7. I am copying a very interesting passage from this book. 8. Give this boy something to eat, he is hungry. 9. It is necessary that I should go to the city. 10. Let us make haste, it is very late. 11. I am going out for a little while, and shall be back by dinner-time.

#### KEY TO EXERCISE XIX.

Parlavano or parlàrono. Parlàrono (essi)?  
Ami? Imparaste? Io non lavai. Pagheremo.  
Dimenticchiàmo. Cantate? Non domandare.  
Se voi portaste. Se noi compràssimo. Essi

Continued

perdonerebbero. Bruciare. Assicurato. Quando entrai. Egli entrò or entrava. Se io entrassi. Lavorando. Avendo copiato. Avremo pagato. Cominceremo. Pensammo. Impararono. Se avessi studiato. Credo (penso) che abbiamo accettato. Preghiamo. Consiglieremmo. Avremmo rifiutato. Non mancherò. Non hanno mandato? Credevo (pensavo) che avessero mandato.

Note that the verb to do in the interrogative, negative, and interrogative-negative forms is not translated: Did he ask? (asked he?), domandò, etc.

#### KEY TO EXERCISE XX.

1. We study Italian. 2. This year we have travelled all the winter, and will travel again this autumn. 3. It is necessary that you should think of your future. 4. If we had listened to your counsels, we should still have all our money. 5. I ate very little, but you ate nothing at all. 6. We shall meet our friends in Paris, and will come back to London together. 7. Let us hope that all will arrive safely. 8. By making mistakes one learns. 9. If we had worked more we should have already finished our work; now who knows if we shall have finished it when our master asks for it? 10. Did you arrive in time the other evening? 11. I think it will soon snow. 12. Look, but do not touch. 13. Let us not forget to help the poor. 14. I had already copied the letter when he entered. 15. Take this letter to its address, please. 16. When they arrived they found the door closed.

| <i>Ne donnant pas</i> | <i>N'ayant pas donné</i> |

Interrogative Conjugation

1. When a verb is used interrogatively, the subject is placed after it in the simple tenses, and between the auxiliary and the past participle in the compound tenses:

*Que penseront-ils de nous ?* What will they think of us ?

*Nous avez-vous envoyé du raisin ?* Have you sent us any grapes ?

2. When the verb ends in mute *e* in the first person singular, it takes an acute accent, to prevent two mute syllables from following each other. This occurs in the first person singular of the present indicative of the first conjugation—*donné-je ?* do I give ?—and in the pluperfect subjunctive, when it is used as a second form of the past conditional:

*Eussé-je mieux fait de ne rien dire ?*

Would I have done better to say nothing ?

3. When the third person singular of the verb or of its auxiliary ends with a vowel, the subject is joined to it by the letter *t* between two hyphens: *donne-t-il ?* does he give ? *a-t-il donné ?* has he given ? This *t* is not merely "euphonic," as it is sometimes called; it is a survival of the Old French form, in which, as in Latin, the third person singular ended with that letter.

4. If the verb has a noun for its subject, that noun does not come after the verb. It takes its place as in an ordinary affirmative or negative sentence, and a personal pronoun agreeing with it is placed after the verb, or the auxiliary:

*Does that lady sing ? Cette dame chante-t-elle ?*

*Has your brother lent you his book ? Votre frère vous a-t-il prêté son livre ?*

5. If the noun be accompanied by the interrogative adjective *quel*, the verb does not require to be followed by a personal pronoun:

*Quelle raison peut triompher du préjugé ?* What reason can overcome prejudice ?

6. Interrogative sentences are very frequently formed without inversion, by the use of *est-ce que*. Its place is immediately before the verb:

*Est-ce que vous le connaissez ?* Do you know him ?

*Est-ce que vous lui avez écrit ?* Have you written to him ?

This form is particularly used to avoid the awkward and harsh inversion of *je* in the first person singular of the present indicative, thus : *Est-ce que je chante faux ?* rather than, *Chanté-je faux ?* Am I singing out of tune ? *Est-ce que je lis trop bas ?* rather than, *Lis-je trop bas ?* Am I reading too low ?

## GERMAN

Continued from  
page 3506

By P. G. Konody and Dr. Osten

### LXV. Use of the Tenses of Verbs.

1. The PRESENT is used in German :

(a) In sentences and general remarks without any limitation of time : *Shakespeare ist* (pres.) *der größte Dichter aller Zeiten*, Shakespeare is the greatest poet of all times. *Wer Geduld hat, kommt zum Ziele*, He who has patience arrives at his goal. Proverbs and similar sentences that are independent of time are generally expressed in the present tense.

(b) In place of the future tense, if the action is regarded as sure to take place, or if the future is already indicated by an appropriate adverb of time : *Ich bin* (pres.) *mergen bei dir*, I am [shall be] with you to-morrow. *Nächste Woche gehe ich fort*, Next week I go away, etc.

(c) In place of the imperfect, if the narration is to be given more vivacity and liveliness : *Ich begegnete ihm ; er sah mich ; er grüßte mich ; ich danke ihm ; wir sprachen eine Weile, und er geht fort ; I met him ; he saw me ; he greets me ; I thank him ; we talk for a while, and off he goes.*

(d) In some cases, where the present perfect tense is used in English, as after the adverbs *schon*, *already*, and *seit*, *since* : *Ich kenne ihn seit zehn Jahren*, I have known him for ten years [I know him since ten years].

(e) Where the progressive form is used in English, or where the English sentence is formed with the aid of the verb "to do," I am going, I am reading, I do not believe, etc. are rendered in German by : *ich gehe, ich lese, ich glaube nicht*, etc. The literal translation (*ich bin gehend, ich tue nicht glauben*) is absolutely inadmissible.

2. The IMPERFECT is used in narrating a past action, or an action not yet finished, when another occurrence sets in : *Im Anfang schuf Gott Himmel und Erde ; die Erde war wüst und leer ; In the beginning God created heaven and earth ; earth was barren and empty.* The imperfect is the common tense of narration.

3. The PERFECT is used to express past actions, or events without any temporal connection with any other actions or events : *Ich bin im Garten gewesen*, I have been in the garden. *Der Zug ist abgegangen*, The train has started ; but : *der Zug ging* (imperfect) *ab, als ich ankam*, The train started when I arrived. As in English, the perfect is often used to replace the clumsy second future : *Ich werde kommen, wenn ich meine Arbeit beendet habe* (instead of : *beendet haben werde*), I shall come when I have finished my work.

*Est-ce que* is also used in the affirmative-interrogative form to indicate that the answer "no," and in the negative-interrogative form to indicate that the answer "yes" is expected :

*Est-ce que cela nous regarde ?* That does not concern us, does it ?

*Est-ce que vous ne me croyez pas ?* You believe me, do you not ?

4. The PLUPERFECT is used as in English.

5. The FIRST and SECOND FUTURE are used as in English, and also in the place of the present and the perfect, when doubt or certain limitations are to be expressed : *Ich werde mich wohl irren* (first future), I am (pres.) probably mistaken ; and *ich werde mich wohl geirrt haben* (second future), I have probably been mistaken.

LXVI. The INFINITIVE PRESENT is employed in German either with or without the preposition *zu*, to ; the one is the "prepositional," the other the "pure" infinitive.

1. The *pure infinitive* is used :

(a) substantively with the article : *das Denken*, thinking ; *das Lernen*, studying ; and

(b) after the verbs *wollen*, *lassen*, *dürfen*, *mögen*, *müssen*, *fönnen*, *lassen*, *hören*, *heißen*, *lehren*, *lernen*, *sehen* (see), *machen* (make), *bleiben* (stay), *helfen* (help), *föhlen* (feel), *gehen* (go), [see LXII].

2. The *prepositional infinitive* is used :

(a) As a gerundial infinitive or attribute of a noun : *Die Kunst zu schreiben war den Ägyptern bekannt*, The art of writing [to write] was known to the Egyptians. *Die Hoffnung zu siegen belebte ihren Mut*, The hope of conquering inspired their courage. *Die Aussicht die Stelle zu erlangen erregte ihn*, The prospect of getting [to get] the position delighted him.

(b) Verbs with stressed prefixes [see XXVIII. I, page 1878] insert the "zu" of the prepositional infinitive between the prefix and the verb, the whole being contracted into one word : *Ich wollte nicht abreißen* (pure infinitive after the verb *wollen*), I would not depart ; and *Ich befohl ihm abzureisen*, I ordered him to depart (prepositional infinitive with "zu" inserted between the separable prefix "ab" and the verb "reisen").

(c) The prepositional infinitive is also used as the *object* of transitive verbs : *Ich heisse jenzukommen*, I hoped to get away ; *er beabsichtigte zu stehlen*, He intended to steal ; or to modify adjectives : *Es ist schwer zu glauben*, It is difficult to believe ; or with attributive meaning, especially after the verbs *sein* and *bleiben* : *Es ist zu ertragen*, It can be endured [it is to endure] ; *Es bleibt zu hoffen*, It remains to be hoped ; *Es wäre zu wünschen*, It would be desirable [to desire]. It is also used as *subject* : *Abzureisen wäre seine Pflicht gewesen*, To depart would have been his duty ; *Gutes zu tun war sein stete Sorge*, To do good was his incessant endeavour ; and with the preposition *um*, to denote purpose : *Er kam, um zu entscheiden*, He

came to decide [for the purpose of deciding]; *Er ging hin, um sich zu vergewissern*. He went there to make sure (of it). *Sie setzte sich ans Klavier, um zu üben*. She sat down at the piano to practise.

(d) In the case of reflective verbs the preposition is placed in the infinitive present between the personal reflective pronoun *sich* and the infinitive: *sich zu ärgern*, to be vexed [literally: to vex oneself]; and in the infinitive past between the past participle of the verb and the infinitive of the auxiliary verb: *sich geärgert zu haben*, to have been vexed [to have vexed oneself].

(e) From the prepositional infinitive present a participle present can be formed by a final -b (*zu leben-b*), which is used attributively with substantives and is declined like an adjective: *Der zu vollendete Bau* (in the sense of: the structure that has to be finished); *die Frau des zu ehrenden Künstlers* (the wife of the artist to whom honour is due).

## LXVII. Affirmation and Negation.

The affirmative answer to the questions: have you . . . ? are you . . . ? is there . . . ? etc. (I have, I am, there is) is not usually employed in German, but is generally replaced by "yes" and "no": *Jaß du den Brief?* Have you the letter? *Ja*, yes; *waren Sie dort?* Were you there? *Nein*, no. Only if special stress is to be laid on the answer, the verb may be used, but always accompanied by a corresponding pronoun, adverb, etc.: *ich habe ihn (den Brief)*; *ich war nicht dort*, I was not there. The answer to the question: *„Jaß du den Brief?“* can under no circumstances be: *„Ich habe!“* The English answer to "do you . . . ?" "I do" "I do not" is also always replaced in German by *ja* and *nein*. The employment of *„tu“*, to do, in a question is altogether unknown in German. The assertion *ja* is sometimes replaced by *doch*, especially in answers to negative questions: *Sie waren nicht dort?* You were not there? *Doch!* or *O, doch!* Certainly, I was. *Ja* is sometimes inserted in sentences to signify that the assertion is well known: *Wir hatten es ja alle gehört*, We all had heard it (as you know). In these cases the *ja* can also be replaced by *doch*: *wir hatten es doch alle gehört*.

## LXVIII. Use of the Moods.

The indicative is the mood of certainty, the subjunctive the mood of supposition, possibility, wish, request, command, civility, and advice; and their employment in independent sentences or in subordinate clauses is determined by the character of the action or event which has to be expressed. Thus the moods can be classified as follows: the indicative is the mood of fact and positive occurrence, whilst the subjunctive is the mood of supposition, suggestion, probability, of which the reality is not fully ascertained.

1. The subjunctive is used very extensively in German, also in indirect speech (*oratio obliqua*) for rendering quotations with circumlocution: *Der Vater meinte, daß dies nicht rätlich sei*, The father thought that this was not advisable; *Ich sagte ihm, daß er gehen könne*, I told him that he could go; *Ich glaubte, daß er dagewesen sei*,

I thought that he had been here. To express a wish: *Möge Gott uns helfen!* May God help us! *Friede sei mit Euch!* Peace be with you! Also in a suggestive sense: *Wärden Sie so gut sein?* Would you be so kind? *Könnten Sie mir nicht sagen?* Could you not tell me? etc.

2. As the indicative is the mood of certainty, and the subjunctive the mood of uncertainty, *glauben* and similar verbs rule either mood, according as the statement is positive or subject to doubt: *Ich wußte, daß er dagewesen ist* (indicative), I knew that he had been here; and *Ich glaube, daß er dagewesen sei* (subjunctive), I believed that he had been here.

3. The tenses used in the subjunctive correspond generally with those which would be employed in the indicative in cases where certainty is expressed or direct speech is rendered. The imperfect and pluperfect subjunctive are employed instead of the present and perfect subjunctive, where an ambiguity may arise from similarity of sound of these forms. Thus instead of: *die Mutter meinte, die Kinder laufen immer* (present subjunctive) *davon*, The mother said the children always run away, it is correct to say: *die Mutter meinte, die Kinder liefen* (imperfect subjunctive) *immer davon*, because the third person plural of *laufen* is the same in the indicative and subjunctive. In the same way the conditional is used instead of the future: *Er sagte, sie würden gehen*, instead of *er sagte, sie werden gehen* („werden“ being sounded the same in both moods).

4. If the direct speech is changed into the indirect in principal sentences, the tense generally remains the same in the subjunctive as it was in the indicative. But where the imperfect indicative is used in the direct speech, the perfect takes its place in the indirect speech. In the same way the perfect subjunctive replaces the pluperfect indicative: *Sie ging* (imperfect indicative) is changed into . . . *daß sie gegangen sei* (perfect subjunctive). The perfect of the subjunctive is employed instead of the imperfect and pluperfect indicative, with the conjunctions *ehe*, *bevor*, *before*; and *nachdem*, *after*. Thus, *sie ging, ehe ich kam*, She went before I came, is changed in indirect speech into: *Man sagte mir, daß sie gegangen sei, ehe ich gekommen wäre*.

5. The imperative of direct speech is expressed in indirect speech by circumlocution with the auxiliary verbs of mood *sollen* and *mögen*: *Er soll kommen, er mag gehen*, is expressed in indirect speech by: *Er sollte kommen, er möge gehen*.

6. The subjunctive is used in subordinate clauses introduced by the conjunctions *daß*, *damit*, *als ob*, etc.: *Er meinte, daß er nicht gehen* (present subjunctive); *Ich sagte, daß er nicht dagewesen wäre* (pluperfect subjunctive); *Wir schien, als ob ich sie* (imperfect subjunctive), It seemed to me, as though I fell.

LXIX. The ENGLISH GERUND is often expressed in German by the prepositional infinitive [see LXVI., 2], with or without the aid of different adverbs: "Instead of speaking, he walked away silently" is rendered in German

by: *Satt zu sprechen* (prepositional infinitive) ging er still fort. The gerund is also frequently replaced in German by subordinate clauses: He thanked the man for having helped him, *Er dankte dem Manne dafür, daß er ihm geholfen hatte*; My calling on him was perfectly superfluous, *Es war vollkommen überflüssig, daß ich ihn besuchte*.

**XXX Position of Words.** In the sentence: *Der Vater schreibt einen Brief*, the father writes a letter, the subject (*Vater*), predicate (*schreibt*), object (*einen Brief*), stand in the normal position, as in English, the subject preceding the predicate, etc. The arrangement of words in the normal sentence can be changed, and the sentence altered in form:

1. Der Vater schreibt einen Brief.
2. Schreibt der Vater einen Brief?
3. Einen Brief schreibt der Vater.
4. . . . . der Vater einen Brief schreibt.

1. Arrangement 1. is the normal one, with the predicate, in the simple tenses, between the subject and the object, and in the compound tenses between the finite verb and the past participle or infinitive: *Der Vater hat einen Brief geschrieben*.

2. If the predicate changes its place by *preceding* the subject, the sentence is altered into the form of a question.

3. In the form: *Einen Brief schreibt der Vater* (literally: a letter writes the father), in which the *object* introduces the sentence, the remaining words being left in their normal position, a simple inversion takes place, in order to lay stress on a certain part of the sentence: *Schreibt der Vater eine Rechnung, einen Brief, oder ein Gedicht?* (does the father write an invoice, a letter, or a poem?) is answered by this form in order to emphasise the object, as well as for reasons of euphony.

4. (a) The fourth form can only be employed in subordinate clauses introduced by subordinate conjunctions, such as *daß, ob, sobald, weil, da, trotzdem, etc.*: *Sei ruhig, weil der Vater einen Brief schreibt*, *Be quiet, because the father writes a letter*; *Ich weiß, daß der Vater einen Brief schreibt*, *I know that, etc.* The conjunction *doch* or *jedoch*, but, admits both the normal and the inverted form: . . . . *doch* der Vater schreibt einen Brief, and . . . . *doch* schreibt der Vater einen Brief. *Die Mutter schläft, doch der Vater schreibt einen Brief*, *The mother sleeps, but the father etc.*; and: *Der Vater ist da, doch schreibt er einen Brief*, *The father is here, but etc.*

(b) If a compound tense is employed the arrangement is as follows:

1. Der Vater hat einen Brief geschrieben.
2. Hat der Vater einen Brief geschrieben?
3. Einen Brief hat der Vater geschrieben.
4. . . . . der Vater einen Brief geschrieben hat.

In 1. the object stands between the finite verb and its participle; in 4. the finite verb is placed at the end, which is the characteristic feature of the subordinate clause.

### EXAMINATION PAPER XVIII.

1. Under what circumstances are the present, the imperfect, the perfect, and the pluperfect tenses used in German?

2. In which forms is the infinitive employed?
3. What difference is to be noted between the English and the German form of affirmative and negative answers to the questions: have you . . . ? are you . . . ? is there . . . ? etc.
4. What words are used in German for the affirmation, and when are they employed?
5. When is the subjunctive used in German, and what can be expressed by this mood?
6. How are the tenses affected when the verb passes from the indicative to the subjunctive mood?
7. By what tense is the English gerund frequently replaced in German?
8. How is a question expressed in a simple sentence?
9. What is the relative position of the words in a subordinate clause?

### KEY TO EXERCISE IN EXAMINATION PAPER XVI. (PAGE 3216)

**EXERCISE 2. (a) Positives:** *Ich werde gern zu Ihnen kommen. Es ist kühl im Garten. Er veranfaltete Alles gut. Unsere Pferde liefen schnell. Die Mose recht süß. (Er zielt genau. Superlative: Ich werde am liebsten, etc. Es ist am kühlfsten, etc. Er veranfaltete Alles aufs Beste. Unsere Pferde liefen am schnellsten. Die Mose recht am süßesten. (Er zielt am genauesten.*

(b) *Er war der jüngste Sohn der Familie. Wir waren die schlauesten Schüler in unserer Klasse. Ich sitze unter dem schattigsten Baume. Erzählen Sie uns die lustigste Geschichte. Er heiratete das reichste Mädchen.*

(c) *Maximilians siegreichster Feldzug. Des Menschen schönste Tier ist die Weisheit. Des Waldes edelstes Tier ist der Hirsch.*

(d) *Ich danke Ihnen bestens. Ich danke Ihnen herzlich. Grüßen Sie ihn sehrstens. Ich empfehle mich ergebenst.*

### KEYS TO EXERCISES IN EXAMINATION PAPER XVII. (PAGE 3356)

**EXERCISE 1.** *Ich habe nicht gewollt. (Er hat nicht gekonnt. (Er hat nicht kommen können. Sie hat nicht kommen wollen. Wir haben nicht spielen dürfen. (Er hat mich helfen lassen. Sie hat es mich wissen lassen. (Er hat fliehen müssen. Ich habe die Kinder spielen sehen. Die Bauern haben ihn hören müssen. (Er hat nicht zu kommen brauchen. Der Vater hat es mich tun heißen (or geheißen). Wir haben ihn kommen sehen. Wir haben sie singen hören. Ich habe ihn aufstehen helfen. Die Geschichte hat sie weinen machen (or gemacht).*

**EXERCISE 2. (a)** *Der Korb wird vom Kinde getragen. Die Musik wird vom Publikum gehört. Die Zeitung wird vom Vater gelesen. Die Tier werden von der Mutter gefodt. Der Hund wird vom Kinde genetzt.*

(b) **Imperfect:** *Der Feind wurde besiegt. Du wurdest geliebt. (Er wurde ausgelacht. Wir wurden geachtet. Ihr wurdet betrogen. Sie wurden aus der Schule ausgeschlossen. Perfect: Der Feind ist besiegt worden. Du bist geliebt worden. Er ist ausgelacht worden. Wir sind geachtet worden. Ihr seid betrogen worden. Sie sind aus der Schule ausgeschlossen worden. First Future: Der Feind wird besiegt werden. Du wirst geliebt werden. Er wird ausgelacht werden. Wir werden geachtet werden. Ihr werdet betrogen werden.*

## LANGUAGES - GERMAN

Sie werden aus der Schule ausgeschieden werden.  
(c) *Pluperfect*: Der Keim war befestigt worden.  
Du wärest geliebt worden. Er war eingeladen worden.  
Wir waren geachtet worden. Ihr wart betrogen worden.  
Sie waren aus der Schule ausgeschieden worden.

*Second Future*: Du wirst werden.  
Du wirst geliebt werden. Du  
werden sein. Wir werden geachtet werden. Ihr  
werdet betrogen werden sein. Er  
Scheide aus der Schule ausgeschieden werden sein.

## CONVERSATIONAL EXERCISES

The following exercises deal with the principal topics of conversation required when in Germany. They begin at the railway station and concern incidents in the daily life of the student abroad.

### I. Railway Station

Where is my luggage?

How many pieces have you?

I have one big trunk, one bag, and a hat box.

Do you wish to have your luggage registered?

Yes, but only the trunk and the hat box.

Have you got your ticket yet?

Are there any smoking compartments in this train?

Yes, and also a dining car.

Where do I change, please?

Not at all.

Do you object to this window being opened?

Not in the least.

I beg your pardon for inconveniencing you.

What is the name of this station?

What o'clock is it, please?

At what time do we arrive at Cologne?

About midnight.

Do you stay at Cologne, or do you go on to Frankfurt?

I intend to stay two days in Cologne.

Don't miss seeing the Cathedral.

How many minutes does the train stop at this station?

Ten minutes, at least.

Time enough to eat something.

May I trouble you for the railway guide?

Could you kindly recommend me a good hotel?

With pleasure! There are only two decent hotels in the town.

Would you be good enough to give me the names and addresses?

The "Bear" is a first class house and rather expensive, whilst the "Eagle" is cheaper and frequented principally by business men.

I believe we shall arrive soon.

Yes, this is Cologne.

This is the famous bridge across the Rhine.

I have been pleased to make your acquaintance.

Will you kindly call a porter?

How far is the hotel?

Just opposite the station.

Then it is not necessary to take a cab?

It is only two minutes from here.

Have you the ticket for the luggage?

What colour is your trunk?

Green with white stripes.

There, I see it!

I keep my bag and my umbrella.

That building with the tower is the hotel.

It seems to be very extensive.

Wie ist mein Gepäck?

Wie viel Stücke haben Sie?

Ich habe einen großen Koffer, eine Tasche und eine  
Gefäßbox.

Wünschen Sie Ihr Gepäck aufzugeben?

Ja, aber nur den Koffer und die Gefäßbox.

Haben Sie schon Ihre Karte?

Gibt es Rauch-Gewerks in diesem Zuge?

Ja, und auch einen Speisewagen.

Wie muß ich umsteigen, bitte?

Nur nicht.

Haben Sie etwas dagegen, wenn dieses Fenster  
geöffnet wird?

Nicht im mindesten.

Ich bitte um Vergebung, daß ich Sie störe.

Wie heißt diese Station?

Wie viel Uhr ist es, bitte?

Um wie viel Uhr kommen wir in Köln an?

Umgeteilt um Mitternacht.

Wollen Sie in Köln, oder gehen Sie weiter nach  
Frankfurt?

Ich beabsichtige zwei Tage in Köln zu bleiben.

Verzeihen Sie nicht, den Dom zu sehen.

Wie viel Minuten hält der Zug in dieser  
Station?

Zehn Minuten mindestens.

Zeit genug, um etwas zu essen.

Darf ich Sie um den Eisenbahn-Fahrplan bitten?

Können Sie mir wirklich ein gutes Hotel empfehlen?

Mit Begeisterung! Es gibt nur zwei anständige Hotels  
in der Stadt.

Würden Sie so gut sein mir die Namen und Adressen  
zu sagen?

Der „Bär“ ist ein erstklassiges Haus mit ziemlich teuer,  
während der „Adler“ billiger ist und hauptsächlich  
von Kaufleuten besucht wird.

Sich glänze wir werden bald antreffen.

Ja, das ist Köln.

Dies ist die berühmte Brücke über den Rhein.

Es hat mich gefreut Ihre Bekanntschaft zu machen.

Wollen Sie wirklich einen Gepäckträger rufen?

Wie weit ist das Hotel?

Gerade dem Bahnhof gegenüber.

Dann ist es nicht nötig eine Droschke zu nehmen?

Es ist nur zwei Minuten von hier.

Haben Sie den Gepäckschein?

Welche Farbe hat Ihr Koffer?

Grün mit weißen Streifen.

Dort sehe ich ihn!

Ich behalte meine Tasche und meinen Schirm.

Das Gebäude mit dem Turm ist das Hotel.

Es scheint sehr ausgedehnt zu sein.

*Continued*

END OF VOLUME IV.
